UNIVERSAL DICTIONARY

OF

SCIENCE, ART, LITERATURE, AND PRACTICAL MECHANICS,

COMPRISING A

POPULAR VIEW OF THE PRESENT STATE OF KNOWLEDGE.

ILLUSTRATED BY

NUMEROUS ENGRAVINGS, A GENERAL ATLAS,

AND APPROPRIATE DIAGRAMS.

Sic oportet ad ibram, presertim miscellanæ generis, legendum accedere lectorem, ut solus ad convivium conviva civili. Convivator amittit omnibus satisfacere; et tamen si quid apponitur, quod hujus aut illius palato non respondeat, et hic et ille arbane dissimulant, et alia fercula probant, ne quid contristent convivatorum. *Isaacus.*

A reader should sit down to a book, especially of the miscellaneous kind, as a well-behaved visitor does to a banquet. The master of the feast exerts himself to satisfy his guests; but if, after all his care and pains, something should appear on the table that does not suit this or that person's taste, they politely pass it over without notice, and commend other dishes, that they may not distress a kind host. *Translation.*

DSW

CLERC (John le), a very celebrated writer and critic, was born at Geneva in 1657. At sixteen he could read all the celebrated Latin and Greek authors. After studying at Geneva, he went to France in 1678; returned in 1679, and was ordained a minister of the Genevan church. In 1682 he visited England, preaching in the Walloon and Savoy churches for nearly six months, and then passed over to Holland, and was admitted professor of philosophy, polite literature, and the Hebrew tongue, at Amsterdam. He now published his *Ars Critica*; and in 1686 began, in conjunction with M. de la Crosse, his *Bibliothèque Universelle et Historique*, which was continued to the year 1693, in 26 vols. In 1703 he began his *Bibliothèque Choisie*, and continued it to 1714, when he commenced another work on the same plan, called *Bibliothèque Ancienne et Moderne*, which he continued to his death. In 1691 he married the daughter of the copious Italian writer, Gregorio Leti, by whom he had four children, who all died young. Le Clerc is a divine conspicuous among those who have contended for the right of private judgment, and who, at the same time, dogmatise very freely in the use of their own. He evidently leans towards the Socinian school, and treats the Scriptures occasionally with little reverence. His writings, however, are valuable, and, as a whole, should not be neglected by the biblical student. In 1728 he was seized with a palsy and fever; and, after spending the last six years of his life in a state of mental imbecility, died in 1736.

CLERC (John le), called Chevalier, an eminent historical painter, born at Nancy in 1597. He studied in Italy, where he resided twenty years, and was a disciple of Carlo Venetiano, whose style he so effectually imitated, that several of his pictures passed for the work of Venetiano. He was highly esteemed at Venice, and, as a token of public respect, was made a knight of St. Mark. His freedom and lightness of coloring, in which he resembled his master, were the principal beauties of his paintings. He died in 1632.

CLERC (Sebastin le), engraver and designer to the French king, was born at Metz in 1637. In 1672 he was admitted into the royal academy of painting and sculpture; and in 1680 made professor of geometry and perspective. He published, besides a great number of designs and prints: 1. A Treatise on Theoretical and Practical Geometry. 2. A Treatise on Architecture; and other works. He died in 1714.

CLERGY, *n. s.*) Fr. *clergè*; Lat. *clerus*;
CLERGYMAN, *n. s.*) Greek κληρος, i. e. sorte deligo, the clergy being regarded as the lot or inheritance of God. See onward. The body of

the Christian ministry. A clergyman is a man in holy orders; set apart for the ministration in the pulpit, and at the altar.

But fame! here as we ride on the way,
 Us nedeth not to spoken but of game
 And let auctoritees, in Goddes name,
 To preaching, and to scole, eke, of *clergie*.

Chaucer. Canterbury Tales.

We hold that God's *clergy* are a state which hath been, and will be as long as there is a church upon earth, necessary, by the plain word of God himself; a state whereunto the rest of God's people must be subject, as touching the things that appertain to their soul's health.

Hooker.

The convocation give a greater sum
 Than ever, at one time, the *clergy* yet
 Did to his predecessors part withal. *Shakspeare.*

How I have sped among the *clergymen*,
 The sums I have collected shall express. *Id.*

Not a few years before the Normans came, the *clergy*, though in Edward the confessor's days, had lost all good literature and religion, scarce able to read and understand their Latin service; he was a miracle to others who knew his grammar.

Milton. History of England.

It seems to be in the power of a reasonable *clergyman* to make the most ignorant man comprehend his duty.

Swift.

CLERGY, as a general name given to the body of ecclesiastics, has been traced to every age of the Christian Church; and some have contended that it is sanctioned by the authority of Scripture. Others conceive that it had its rise at a later period, when the desire of spiritual and secular pre-eminence, and corresponding dominion had perverted the minds of the professors and teachers of Christianity; and the interests of the church became interwoven with that of the state. It is a probable opinion that it was established before the time of Tertullian, towards the close of the second century.

The distinction itself was intended, we are told, to suggest, that the former, that is, the pastors or clergy (for they appropriated the term κληρος to themselves), were selected and contradistinguished from the multitude, as being, in the present world, by way of eminence, God's 'peculium,' or special inheritance. In support of this claim they allege, that God is, in the Old Testament, said to be the inheritance of the Levites, because a determinate share of the sacrifices and offerings made to God was, in part, to serve them instead of an estate in land, such as was given to each of the other tribes. But it has been argued, on the other hand, that the tribe of Levi is nowhere called God's inheritance, though that expression is repeatedly used, with respect to the whole nation. Concerning the whole nation of Israel, Moses, who was himself

a Levite, says, in an address to God, Deut. ix. 29, 'They are thy people, and thine inheritance, which thou broughtest out by thy mighty power.' The words in the Septuagint deserve our particular attention. "Οἱ τοὶ λαὸς σε καὶ κληρὸς σε ἐξ ἐγγύων ἐκ γῆς. Αἰγύπτῳ ἐν τῇ ισχύϊ σε τῇ μεγάλῃ. The same persons are, in the same sentence, declared to be both the λαὸς and the κληρὸς. What says the canonist, at once laymen and clergy? That is certainly absurd; the characters are incompatible; yet it did not then appear so to Moses. Nor would it be thought reasonable or just, that what was allowed to be the privilege and the glory of every Israelite, under the more servile establishment of Moses, should, under the more liberal dispensation of the gospel, be disclaimed by all those disciples of Jesus who have not been admitted into the sacred order, which they, for this reason, have called clerical. As to the use of the term in the New Testament, one passage, as the persons to whom we now refer argue, and only one, occurs, in which it is applied to persons. (See 1 Peter. v. 3). The words in the original are, μηδὲ ὄς κατακλιμένοι τῶν κληρῶν, ἀλλὰ τυποὶ γινόμενοι τοῖς ποιμῖνι; thus rendered in our version, 'Neither as being lords over God's heritage, but being ensamples to the flock.' They are part of a charge given to the presbyters, or pastors, relating to their care of the people committed to them, who are called God's flock, which they are commanded to feed, of which they are to take the oversight, not the mastery, and to which they are to serve as patterns. The same persons, therefore, who, both in this and in the preceding verse are styled ποιμῖνοι, the flock, under the direction of God's ministers, the shepherds, are also called κληροί, his inheritance, over whom their pastors are commanded not to domineer. The distinction above mentioned, it is said, stands in direct contradiction both to the letter and to the sense of the unerring standard of Scripture. Some expositors, however, render the term κληροί, in this passage, the church's possessions; but this explication, as others say, ill suits the context, and annihilates the contrast between an imperious manner and an engaging pattern, and supposes an awkward ellipsis in the words themselves. Besides, it is asked what were the church's possessions in those days? Was she so early vested with lands and hereditaments, for it is to such only that the term κληροί, when denoting property or possession, is applied? In the apostolic times, the church's patrimony consisted chiefly in persecution and calumny, hatred and derision, agreeably to the prediction of her Lord.

The distinction of the whole church into clergy and laity, whensoever it originated, was soon extended much farther than the original intention of those who adopted it. In the time of Cyprian, about the middle of the third century, we find that, in general, all things relating to the government and policy of the church were performed by the joint consent, and administration of the clergy and laity. Thus Cyprian says (Epist. vi. § 5, cited by the author of the Enquiry into the Constitution, &c. of the Primitive Church, p. 106), 'he did nothing without the knowledge and consent of his people.' That the

letters from foreign churches were received and read by the whole church, &c.

The origin of the term laity becomes a curious matter of enquiry in this connexion. The schoolmen will not allow it to be derived from λαὸς, populus; they deduce it from lapis, a stone. The following specimen of the mode of reasoning adopted by some celebrated doctors, and cited by Altensfaig in his Lexicon Theologicum, is possibly amusing. 'Capitur clericus pro viro docto, scientifico, perito, scientia pleno, repleto et experto. E contra, laicus capitur pro viro indocto, imperito, insipientie, et lapideo. Unde laicus dicitur a λαὸς Græcè, quod est lapis Latinè. Et sic omnis clericus, in quantum clericus, est laudabilis; laicus vero, in quantum laicus, est vituperandus. Clerici quoque a toto genere de jure proponuntur, et debent præponi laicis.' Cardinal Bona also delivers his sentiments in relation to the care that ought to be taken by the clergy, that laymen may not be allowed to do themselves harm by studying the profounder parts of Scripture, which their stupidity is utterly incapable of comprehending; and though he does not absolutely prohibit their reading some of the plainer books of Scripture, he indulges them more freely in the use of books containing the histories, lives, and legends of the saints, and holy meditations. See more on this subject in *Campbell's Ecclesiastical History*, vol. i.

In the first century the clergy were distinguished by the title of presbyters or bishops; and some maintain that they are of equal rank and authority. See BISHOP. But towards the close of the second century, a notion prevailing that the ministers of the Christian church succeeded to the character, rights, and privileges of the Jewish priesthood, this produced a subordination of rank among them. The bishops assumed a rank and character similar to those of the Jewish high-priest; the presbyters represented the priests, and the deacons the Levites. This distinction was still farther promoted towards the end of the third century; and a new set of ecclesiastical officers was established, such as subdeacons, acolythi, door-keepers, readers, exorcists, &c. The powers of the clergy were considerably extended under Constantine, and the Romish Church attained its full, and finally intolerable, height.

In that church are two very distinct orders of clergy: one regular, comprehending all the religious of both sexes, as abbots, monks, priors, &c.; the other secular, comprehending all the ecclesiastics that do not make the monastic vows. Among the reformed churches, there are none but those of the latter.

In England the term clergy comprehends all persons in holy orders, and ecclesiastical offices: and, though their almost total exemption from the duties of civil life has been modified since the Reformation, important personal exemptions, essential to their sacred office, are still continued to them. Clergymen cannot be compelled to serve on a jury, nor to appear at a court-leet, which almost every other person may be obliged to do; but if a layman is summoned on a jury, and before the trial takes orders, he shall, not

withstanding, appear and be sworn. Neither can he be chosen to any temporal office, as bailiff, reeve, constable, or the like; in regard of his own continual attendance on the sacred function. During his attendance on divine service, he is privileged from arrests in civil suits. In cases also of felony, a clerk in orders shall have the benefit of clergy, without being branded in the hand; and may likewise have it more than once; in both which cases he is distinguished from a layman. But, as they have their privileges, so they have also their disabilities, on account of their spiritual avocations. Clergymen are incapable of sitting in the House of Commons; and by statute 21 Hen. VIII. c. 13. are not, in general, allowed to take any lands or tenements to farm, upon pain of £10 per month, and total avoidance of the lease; nor, upon like pain, to keep any tap-house or brew-house; nor engage in any trade, nor sell any merchandise, under forfeiture of the treble value; which prohibition is consonant to the canon law.

CLERGY, BENEFIT OF, an ancient privilege, whereby one in orders claimed to be delivered to his ordinary to purge himself of felony. The old exemptions granted to the church were principally of two kinds: 1. Exemption of places consecrated to religious duties from criminal arrests, which was the foundation of sanctuaries. 2. Exemption of the persons of clergymen from criminal process before the secular judge in a few particular cases, which was the true and original meaning of the *privilegium clericale*. But the clergy increasing in wealth, power, number, and interest, now claimed that which they obtained by the favor of the civil government, as their inherent right, and as a right of the highest nature, indefeasible, and *jure divino*. By their canons, therefore, and constitutions, they endeavoured at, and often obtained a vast extension of those exemptions; as well in regard to the crimes themselves, of which the list became universal, as in regard to the persons exempted; among whom were at length comprehended, not only every subordinate officer belonging to the church or clergy, but even many that were entirely laymen. In England, however, a total exemption of the clergy from secular jurisdiction could never be thoroughly effected. And, in those particular cases in which it was allowed, the custom was for the bishop or ordinary to demand his clerks to be remitted out of the king's courts as soon as they were indicted: concerning the allowance of which demand there was, for many years, a great uncertainty; till at length it was finally settled in the reign of Henry VI. that the prisoner should first be arraigned; and might either then claim his benefit of clergy by way of declinatory plea; or, after conviction, by way of arrest of judgment. This latter way is most usually practised, as it is more to the satisfaction of the court to have the crime previously ascertained by confession, or the verdict of a jury; and more advantageous to the prisoner, who may possibly be acquitted, and so need not the benefit of his clergy. Originally the law was held that no man should be admitted to the benefit of clergy, but such as had the clerical habit and tonsure. But in time a much wider

criterion was established; every one that could read (a great mark of learning in those days of ignorance) being accounted a clerk, or clericus, and allowed the benefit of clerkship, though neither initiated in clerkship, nor trimmed with the holy tonsure. But when learning became more generally disseminated, and reading was no longer a proof of clerkship, or holy orders, it was found that as many laymen as divines were admitted to the *privilegium clericale*; and therefore by statute 4 Henry VII. c. 13. a distinction was once more drawn between mere lay scholars and clerks that were really in orders. The statute directs, that no person, once admitted to the benefit of clergy, shall be admitted thereto a second time, until he produces his orders: and, to distinguish their persons, all laymen who are allowed this privilege, shall be burned with a hot iron in the brawn of the left thumb. This distinction between learned laymen and real clerks in orders was abolished for a time by the statutes 23 Hen. VIII. c. 1, and 32 Hen. VIII. c. 3, but is held to have been virtually restored by statute 1 Edw. VI. c. 12, which enacts, that lords of parliament and peers of the realm may have the benefit of their peerage, equivalent to that of clergy, for the first offence (although they cannot read, and without being burnt in the hand), for all offences then chargeable to commoners, and also for the crimes of house-breaking, highway-robbery, horse-stealing, and robbing of churches. After this burning, the laity, and before it, the real clergy, were discharged from the sentence of the law in the king's court, and delivered over to the ordinary, to be dealt with according to the ecclesiastical canons. Whereupon the ordinary, not satisfied with the proofs adduced in the profane secular court, set himself formally to make a purgation of the offender by a new canonical trial; although he had been previously convicted by his country, or perhaps by his own confession. This trial was held before the bishop in person, or his deputy, and by a jury of twelve clerks. And there, first the party himself was required to make oath of his own innocence: next, there was to be the oath of twelve compurgators, who swore they believed he spoke the truth; then, witnesses were to be examined upon oath, but upon behalf of the prisoner only; and, lastly, the jury were to bring in their verdict upon oath, which usually acquitted the prisoner; otherwise, if a clerk, he was degraded or put to penance.

By this purgation, the party was restored to his credit, his liberty, his lands, and his capacity of purchasing afresh, and was treated as an entirely innocent man. This scandalous prostitution of oaths, and the forms of justice, in the almost constant acquittal of felonious clerks by purgation, was the occasion that, upon very heinous and notorious circumstances of guilt, temporal courts would not trust the ordinary with the trial of the offender, but delivered over to him the convicted clerk, *absque purgatione facienda*: in which situation the clerk convict could not make purgation, but was to be imprisoned for life, and was incapable of acquiring any personal property, or receiving the profits of his lands, unless the king should pardon him.

The statute 18 Eliz. c. 7, enacts, that, for avoiding such perjuries, and abuses, after the offender has been allowed his clergy, he should not be delivered to the ordinary as formerly; but, upon such allowance, and burning of the hand, he shall forthwith be enlarged, and delivered out of prison; with proviso, that the judge may, if he thinks fit, continue the offender in jail for any time not exceeding a year. And thus the law continued unaltered for above a century; except only, that the statute 21 Jac. 1. c. 6, allowed, that women convicted of simple larcenies under the value of 10s. should (not properly have the benefit of the clergy, for they were not called upon to read; but) be burned in the hand, whipped, or stocked, or imprisoned for any time not exceeding a year. All women, all peers, and all male commoners who could read, were therefore discharged in such felonies absolutely, if clerks in orders; and for the first offence upon burning in the hand, if laymen; yet all liable (except peers), if the judge saw occasion, to imprisonment not exceeding a year. And these men who could not read, if under the degree of peerage, were hanged. At last, however, it was considered, that learning was no extenuation of guilt. And thereupon, by statute 5 Anne, c. 6, it was enacted that the benefit of clergy should be granted to all those who were entitled to ask it, without requiring them to read by way of conditional merit. But experience having shown that so universal a lenity was an encouragement to commit the lower degrees of felony; it was enacted that when any person is convicted of any theft or larceny, and burnt in the hand for the same, he shall, at the discretion of the judge, be committed to the house of correction or public work-house, to be there kept to hard labor for any time not less than six months, and not exceeding two years; with a power of inflicting a double confinement in case of the party's escape from the first.

It was also enacted by statute 4 Geo. I. c. 11. and 6 Geo. I. c. 23. that when any person shall be convicted of any larceny, either grand or petit, who by the law shall be entitled to the benefit of clergy, and liable only to the penalties of burning in the hand, or whipping; the court, instead of such burning in the hand, or whipping, may direct such offenders to be transported to America for seven years; and if they return, or are seen at large in this kingdom within that time, it shall be felony without benefit of clergy. In this state does the benefit of clergy at present stand; very considerably different from its original institution; the English legislature having converted, by gradual mutations, what was at first an unjust exemption of popish ecclesiastics, into a merciful mitigation of the general law with respect to capital punishments. All clerks in orders are, without any branding or transportation, to be admitted to this privilege, and immediately discharged, or at most only confined for one year; and this as often as they offend. All lords of parliament, and peers of the realm, by the statute 1 Edw. VI. c. 12. shall be discharged in all clergyable and other felonies provided for by the act without any burning in the hand, in the same manner as real clerks convict: but this

is only for the first offence. All the commons of the realm, not in orders, whether male or female, shall, for the first offence, be discharged of the punishment of felonies, within the benefit of clergy, upon being burnt in the hand, and suffering discretionary imprisonment; or, in case of larceny, upon being transported for seven years. By statute 19 Geo. III. c. 74, burning in the hand is abolished, and instead thereof, except in cases of manslaughter, the court may order the offender to be whipped. Upon the whole, we may observe the following rules: 1. In all felonies, whether new created, or by common law, clergy is now allowable, unless taken away by act of parliament. 2. Where clergy is taken away from the principal, it is not taken away from the accessory, unless he be also particularly included in the words of the statute. 3. When the benefit of clergy is taken away from the offence (as in case of murder, robbery, rape, and burglary, &c.), a principal in the second degree, being present, aiding and abetting the crime, is excluded from his clergy as well as the principal in the first degree: but, 4. Where it is only taken away from the person committing the offence (as in case of stabbing, or committing larceny in a dwelling house,) his aiders and abettors are not excluded, through the tenderness of the law, which had determined that such statutes shall not be taken literally.

CLERK, *n. s.* } Fr. *clerc*; Lat. from *cle-*
 CLERICAL, *adj.* } *ricus*, a clergyman; a lite-
 CLERKSHIP, *n. s.* } rary man: a scribe by pro-
 fession; it received its peculiar application when the clergy were the only penmen. It is now applied to a man employed under another as a writer; a petty writer in public offices; an officer of various kinds. Clerical is applied exclusively to the clergy, except when used in a legal sense to mark the literal errors of clerks and transcribers. Clerkship is the office of a clerk of any kind. It is also used in the sense of apprenticeship by lawyers. A clerk is, according to the usage of the church of England, a reader as well as a writer, one who reads the responses to lead the congregation.

A good man, ther wos of religioun,
 That was a poure persone of a town,
 But rich he wos of holy thought and werk,
 He wos also a lerned man a clerk.

Chaucer's Canterbury Tales.

They might talk of book-learning what they would;
 but, for his part, he never saw more unfeately fellows
 than great clerks were. *Sidney.*

My lord Passanio gave his ring away
 Unto the judge; and then the boy, his clerk,
 That took some pains in writing, he begged mine.
Shakespeare.

In clericals the keys are lined, and in colleges they
 use to line the table-men. *Bacon's Natural History.*

His notions fitted things so well,
 That which was which he could not tell;
 But oftentimes mistook the one
 For the 'other, as great clerks have done.
Hudibras.

All persons were styled clerks, that served in the
 church of Christ, whether they were bishops, priests,
 or deacons. *Ayliffe.*

Take a just view, how many may remark,
Who's now a lord, his grandsire was a clerk.

Granville.

The greatest clerks being not always the honestest,
any more than the wisest, men. *South.*

He sold the clerkship of his parish, when it became
vacant. *Swift's Miscellanies.*

My friend was in doubt whether he could not exert
the justice upon such a vagrant; but not having
his clerk with him, who is a necessary counsellor, he
let the thought drop. *Addison.*

It may seem difficult to make out the bills of fare
for the suppers of Vitellius. I question not but an
expert clerk of a kitchen can do it. *Arbutnot.*

Church ladders are not always mounted best

By learned clerks and Latinists professed. *Cowper.*

CLERK comes from the Greek κληρος, used
for clergy; but more properly signifies lot or heri-
tage, the lot of clerks or ecclesiastics being to
serve God. Accordingly clerus was at first used
to signify those who had a particular attachment
to the service of God. The origin of the ex-
pression is derived from the Old Testament,
where the tribe of Levi is called the lot, heritage,
κληρος; and God is reciprocally called their por-
tion; that tribe being consecrated to the service
of God, and living on the offerings made to God
without any other settled provision. Thus, Pas-
quier observes, the officers of the counts were
anciently stiled clerks of accounts; and secre-
taries of state were called clerks of the secret.
So clerici domini regis, in the time of Edward I.
was Englished, the king's secretary, or clerks
of his council. The term was applied indifferently
to all who knew how to manage the pen: though
originally it was appropriated to ecclesiastics.
As the nobility and gentry were usually brought
up to the exercise of arms, none but the clergy
cultivated the sciences.

CLERK COMPTROLLER OF THE KING'S HOUSE-
HOLD, an officer of the king's court, authorised
to examine and pass the charges of pursuivants,
messengers of the green cloth, &c. to inspect and
control all defects of any of the inferior officers;
and to sit in the counting house with the lord
steward and other officers of the household, for
regulating such matters.

CLERK OF THE BAILS, an officer in the court
of King's Bench, who files all bail pieces taken
in that court, where he always attends.

CLERK OF THE CHECK, an officer belonging to
the king's court; who has the check and control-
ment of the yeomen that belong to the king,
queen, or prince. He likewise, by himself or
deputy, sets the watch in the court. There is also
in the navy an officer of the same title, belonging
to the king's yards.

CLERK OF THE CROWN, an officer in the King's
bench, who frames, reads, and records all indict-
ments against offenders there arraigned or indicted,
of any public crime. He is likewise termed
clerk of the crown office, in which capacity he
exhibits information by order of the court for
divers offences.

CLERK OF THE CROWN, in chancery, an officer
who constantly attends the lord chancellor in
person or by deputy; writes, and prepares for the
great seal, special matters of state by commission
both ordinary and extraordinary, viz. commissions

of lieutenancy, of justices of assize, oyer and ter-
miner, gaol-delivery, and of the peace; all
general pardons, granted either at the king's
coronation, or in parliament. The writs of par-
liament with the names of the knights, citizens,
and burgesses, are also returned into his office.
He likewise makes out special pardons and
writs of execution on bonds of statute-staple
forfeited.

CLERK OF THE ORDNANCE, an officer of the
king's tower who has the registers, &c. of the
ordnance.

CLERK OF THE ERRORS, in the court of com-
mon pleas, an officer who transcribes and certi-
fies into the king's bench, the tenor of the record
of the action on which the writ of error, made
out by the curstior, is brought there to be deter-
mined. In the king's bench, the clerk of the er-
rors transcribes and certifies records of causes,
by bill, in that court, into the exchequer. And
the clerk of the errors in the exchequer, trans-
cribes the records certified thither out of the
king's bench, and to prepare them for judgment
in the exchequer chamber.

CLERK OF THE ESSOINS, in the court of com-
mon pleas, keeps the essoins roll or enters essoins:
he also provides parchment, cuts it into rolls,
marks the number on them, delivers out the rolls
to the officers, and receives them again when
written. See ESSOIN.

CLERK OF THE ESTREATS, an officer in the
exchequer, who every term receives the estreats
out of the lord-treasurer's remembrancer's office,
and writes them out to be levied for the
crown.

CLERK OF THE HAMPER, or HAMAPER, an
officer in chancery, who receives all money due
to the king for the seals of charters, letters patent,
commissions, and writs; also the fees due to the
officers for enrolling and examining them.

CLERK OF THE KING'S SILVER, an officer of
the common pleas, to whom every fine is brought
after it has passed the office of the custos brevium;
and who enters the effect of writs of covenant
into a book kept for that purpose, according to
which all the fines of that term are recorded in
the rolls of the court.

CLERK OF THE MARKET, an officer of the king's
house, who has the charge of the king's measures
and weights, the standard of those that ought
to be used all over England.

CLERK OF THE NICHILS OR NIHILS, an officer
of the exchequer, who makes a roll of all such
sums as are nichilled by the sheriff's upon their
estreats of green wax, and delivers them in to
the remembrancer of the treasury, to have execu-
tion done upon them for the king. See NIHIL.

CLERK OF THE OUTLAWRIES, an officer of the
common pleas, and deputy to the attorney gene-
ral, for making out all writs of capias et legatum
after outlawry, to which there must be the attor-
ney general's name.

CLERK OF THE PAPER OFFICE, an officer be-
longing to the King's Bench, who makes up the
paper books of special pleadings in that court.

CLERK OF THE PEACE, an officer belonging to
the sessions of the peace, who reads indictments,
enrols the proceedings, and draws the process:
he also certifies into the King's Bench, transcripts

of indictments, outlawries, attainders, and convictions before the justices of peace, within the time limited by statute, under a certain penalty. This office is in the gift of the *custus rotulorum*, and may be executed by deputy.

CLERK OF THE PELLIS, an officer in the exchequer, who enters every teller's bill into a parchment roll, called *pellis receptorum*; and makes another roll of payments called *pellis exituum*.

CLERK OF THE PIPE, an officer of the exchequer, who having the accounts of all debts due to the king, delivered out of the remembrancer's office, charges them in a great roll folded up like a pipe. He writes out warrants to sheriffs, to levy the said debts on the goods and chattels of the debtors; and, if they have no goods, then he draws them down to the treasurer's remembrancer to write estreats against their lands.

CLERK OF THE PLEAS, an officer of the exchequer, in whose office all the officers of the court having special privilege, ought to sue or be sued in any action. In his office also actions at law may be prosecuted by other persons, but the plaintiff ought to be tenant or debtor to the king, or some way accountable to him. The under clerks are attorneys in all suits.

CLERK OF THE ROLLS, an officer of the chancery, who makes search after, and copies deeds, offices, &c.

CLERK OF THE TREASURY, an officer belonging to the court of common pleas, who keeps the records of the court, makes out all records of nisi prius, and all exemplifications of records in the treasury. He has the fees due for all searches; and has an under keeper, who keeps one key of the treasury door.

CLERK OF THE WARRANTS, an officer of the common pleas, who enters all warrants of attorney for plaintiffs and defendants in suit; and enrolls deeds of bargain and sale that are acknowledged in court, or before a judge. He likewise estreats into the exchequer all issues, fines, estreats, and amercements, due to the crown in that court.

CLERKS OF THE PETTY BAG, three officers of the court of chancery, of whom the master of the rolls is the chief: their business is to record the return of all inquisitions out of every shire; to make out patents of customers, gaugers, comptrollers, &c. liberates upon extent of statutes staple; conge d'elires for bishops; summonses of the nobility, clergy, and burgesses to parliament; and commissions directed to knights and others of every shire, for assessing subsidies and taxes.

CLERKS OF THE PRIVY SEAL, four officers who attend the lord privy seal, for writing and making out all things that are sent by warrant from the signet to the privy seal, and to be passed the great seal; and make out privy seals, upon special occasions of his majesty's affairs, as for loan of money, or the like.

CLERKS OF THE SIGNET, four officers continually attending upon his majesty's principal secretary, who has the custody of the privy signet, for sealing the king's private letters, and the grants which pass the king's hand by bill signed. They have their diet at the secretary's table.

CLERKE (Captain Charles), a celebrated English navigator, bred up to the navy from his youth, and present in several actions during the war of 1745. In that between the *Bellona* and *Courageux*, having been stationed in the mizen top on board the former, the mast was carried overboard by a shot, and he fell into the sea with it; but was taken up unhurt. When commodore Byron made his first voyage round the world, Mr. Clerke served on board his ship as a midshipman; and was afterwards on the American station. In 1768 he sailed round the world a second time in the *Endeavour*, as master's mate; but, during the voyage, succeeded to a lieutenantancy. He returned in 1775, and was soon after appointed master and commander. When captain Cook undertook his last voyage, Mr. Clerke was appointed captain of the *Discovery*; and, on the death of captain Cook, succeeded to the supreme command. He did not, however, long enjoy his new dignity, having had symptoms of a consumption before his departure from England; notwithstanding which he persevered in search of a passage between the Asiatic and American continents, until all his officers were of opinion that it was impracticable. He died on the 22d of August, 1778, aged thirty-eight, the ship being then within view of the coast of Kamtschatka.

CLERKE'S ISLANDS, two islands in the North Pacific Ocean, between the coast of Kamtschatka in Asia, and that of North America. They were discovered by captain Cook in his last voyage, and named after captain Clerke. At a distance they appeared to be of a considerable extent, and to have several hills, connected with the low grounds in such a manner as to make them look like a group of islands. The little island lies on the eastern extremity of the large one, and is remarkable for having three elevated rocks upon it. Both islands are uninhabited.

CLERKE'S RIVER, a river of North America, which rises on the western declivity of the Rocky Mountains, and, after a winding course round the mountains, falls into the Columbia about the forty-second degree of north latitude, 500 miles above the mouth of the latter. It was named by captains Lewis and Clarke, who first visited this country in their journey across the American continent to the Pacific.

CLERKE'S ROCKS are a cluster of rocky islets in the South Atlantic, about thirty-seven miles south of the island of Georgia. Lat. 55° S.

CLERKENWELL, one of the most populous of the out-parishes of the city of London, in Os-sulton hundred, Middlesex. It consists of the united parishes of St. James and St. John. St. James's church stands on the site of an ancient monastery, and is a heavy structure, built partly in the Gothic and partly in the Tuscan order. On the green is the sessions-house for the county. Here also is the New-Prison, built on the Howardian plan, as well as Clerkenwell bridewell. In St. John's Square formerly stood the famous hospital of St. John of Jerusalem, which was destroyed by the rebels under Wat Tyler in the fourteenth century.

CLERMONT, a county of South Carolina, in Camden district, bounded on the north by Kershaw county, on the east by Salem, on the south by Clarendon, and on the west by the river Wateree, which separates it from Richland county. It is thirty-five miles long and equally broad. The chief town is Statesburg.

CLERMONT, or **CLERMONT FERRAND**, a populous city of France, the capital of the department of Puy de Dome. Before the revolution it was the capital of Auvergne, and the see of a bishop, suffragan of Bourges. From its situation on an eminence at the foot of a lofty mountain, it was originally Clarus Mons. It is now called Clermont Ferrand, from the town of Montferrand being united to it, and forming one of the faux-bourgs. It is said to contain 16,000 inhabitants, and has a considerable commerce in corn, wine, wool, woollen stuffs, tennies, serges, linen, lace, &c. Here are also manufactures of paper, hats, leather, pottery, and linen and woollen stuffs. There are several fine walks and public squares, but the streets are narrow, and the houses mean; being generally built of stone of a gloomy hue. The cathedral is one of the finest in France, though in an imperfect state: of the five towers which existed in the last century, only one has survived the revolution. The college is a fine edifice, containing a public library; here is also a cabinet of natural history, a botanic garden, a good theatre, and several hospitals. Many Roman antiquities have been found in the neighbourhood; and there are several mineral springs near: the water of a brook which passes through the fauxbourg of St. Allyre has petrified a wooden bridge to perfect stone. A council was held here in 1095, to determine on the crusade against the infidels in the Holy Land, during the pontificate of Urban II. It was the birth-place of Paschal; is 233 miles south of Paris, and fifty south of Moulins.

CLERMONT, or **CLERMONT**, **EN ARGONNE**, a town of France, in the department of the Meuse, and ci-devant territory of Barrois. It is seated on an eminence surrounded with woods and pastures; twelve miles W.S.W. of Verdun, and 137 north-west of Paris.

CLERMONT DE LODEVE, a town of France, in the department of Herault, and ci-devant province of Languedoc. It is the capital of a canton in the district of Lodeve. It has manufactures of cloth and hats, but its chief trade is in wool and cattle. It is twenty miles west of Montpellier.

CLERMONT MANUSCRIPT, Codex Cleromontanus or Regius, a Greco-Latin manuscript of St. Paul's Epistles, found in the monastery of Clermont in France, and used by Beza, together with the Cambridge MS., in preparing his edition of the New Testament. This copy is in the 8vo. form, and is written on fine vellum in uncial, Greek and Latin characters, with some mutilations. Beza supposes that it is of equal antiquity with the Cambridge copy; and it is noted D by Wetstein and Griesbach. As it contains the epistle to the Hebrews, which has been however added by a later hand, it is supposed to have been written in the west of Europe. Dr. Mill contended that it was the second part of the

Cambridge MS.; but this opinion has been entirely refuted by a comparison of their form, size, vellum, and more particularly of their abbreviations. The MS. itself was in the possession of Morinus; and, after his death, deposited among the MSS. of the Royal Library at Paris. According to the accounts of Wetstein and Sabatier, thirty-six leaves were cut out of it at the beginning of the last century (by John Aymon, as it is supposed), and sold in England to the earl of Oxford, who however returned them in 1729. The MS. is therefore once more complete, as the covering only is wanting in which the stolen sheets had been enclosed. This is preserved in the British Museum, and filled with the letters that passed on the occasion. The Codex Cleromontanus, together with other Greco-Latin MSS., has been accused of having a Greek text altered from the Latin, but this charge has been entirely refuted by Dr. Semler.

CLERODENDRON, in botany, a genus of plants of didynamia class, and angiospermia order: CAL. five-cleft, campanulate: COR. tube filiform; border, five-parted and equal: STAM. very long, placed between the segments of the corolla: PIST. four-seeded, bearing a one-celled nut. Species eight; trees and shrubs of the East Indies; the former having scarlet, the latter white flowers.

CLEROMANCY; from κληρος, a lot, and μαντεια, magic, a kind of divination performed by the throwing of dice, or little bones; and observing the points, or marks, turned up. At Bura, a city of Achaia, was a temple and celebrated oracle of Hercules; where those who consulted the oracle, after praying to the idol, threw four dies, the points whereof being observed by the priest, he drew an answer from them.

CLERVAUT, or **CLERVAUX**, a town of France, in the department of Vienne, and ci-devant province of Champagne, five miles north of Châtellerault, and as far from Bar sur Aube. Its abbey, seated in a valley surrounded with woods and mountains, was formerly the chief of the Cistercian order, and had the famous tun of St. Bernard, which held 800 tuns of wine.

CLERY, a town of France, in the department of Somme, and ci-devant province of Picardy. It is the capital of a canton in the district of Peronne; and lies three miles north-west of Peronne.

CLESIDES, a Greek painter, who lived about A. A. C. 276, under Antiochus I. He revenged the injuries he had received from queen Stratonice, by representing her in the arms of a fisherman; but she was drawn with such personal beauty, that she preserved the piece, and liberally rewarded the artist.

CLETHRA, in botany, a genus of the monogynia order, and decandria class of plants; natural order eighteenth, bicornes: CAL. quinquepartite; the PETALS five; the STIGMA trifid; the CAPSULE trilocular and three-valved. Species four; the most noted is *C. anifolia*, a native of Virginia and Carolina, where it grows in moist places, and near the sides of rivulets, rising nearly six or ten feet high. The leaves are shaped like those of the alder, but longer; and placed alternately

upon the branches: the flowers are produced in close spikes at the extremities of the branches; they are white, composed of five petals, and have ten stamina in each, nearly of the same length with the petals. This plant will bear the open air in Britain, and is one of the most beautiful flowering shrubs. Its season is commonly about the beginning of July; and, if not very hot, the spikes will flourish till the middle of September. It thrives best in moist land, and requires a sheltered situation, where it may be defended from strong winds, which frequently break off the branches where they are too much exposed to their violence. It is propagated by layers, but they are generally two years before they take root. It may also be propagated by suckers, which are sent out from the roots; if these are carefully taken off with fibres in the autumn, and planted in a nursery-bed, they will be strong enough in two years to transplant.

CLEVE, } In composition, at the beginning
CLIF, } or end of the proper name of a
CLIVE, } place, denotes it to be situated on
the side of a rock or hill; as Cleveland, Clifton, Stauchli.

CLEVELAND, a district of the North Riding of Yorkshire, part of the vale of Stockton. It borders upon Durham, from which it is separated by the Tees; and is remarkably beautiful, fertile, and well cultivated. It contains 70,444 arable acres. Wheat is its staple produce; and no other district in the neighbourhood produces so great a proportionable quantity of equally fine grain.

CLEVELAND (John), an English poet of some eminence, who, during the civil war under Charles I., engaged as a literary champion in the royal cause against the parliamentarians. He died in 1658, and was much extolled by his party. His works, which consist of poems, characters, orations, epistles, &c., were printed in 1677, in 8vo.

CLEVER, *adj.* } Sax. gleawra; proba-
CLEVERLY, *adv.* } bly from γλαφρός. Dex-
CLEVERNESS, *n. s.* } terous, skilful, just; fit;
proper; intelligent; accomplished; handsome; commodious.

These would inveigle rats with the scent,

And sometimes catch them with a snap.

As *cleverly* as the ablest trap. *Hudibras.*

A rogue upon the highway may have as strong an arm, and take off a man's head as *cleverly* as the executioner. *South.*

It was the *cleverer* mockery of the two.

L'Étrange.

I read Dyer's letter more for the style than the news. The man has a *clever* pen, it must be owned.

Addison's Freetholder.

He can't but think 'twould sound more *clever*,

To me, and to my heirs for ever. *Pope.*

She called him gundy-guts, and he called her lousy Peg, though the girl was a tight *clever* wench as any was. *Arbutnot.*

CLEVES, a duchy in Westphalia, on the north-west of Germany, near Holland, including an area of 880 square miles, being about forty miles long and ten or twelve in medium breadth. It is situated chiefly on the south bank of the

Rhine, mostly above the point where that river branches out and forms the great stream called the Waal, between 5° 45' and 6° 25' E. long. and 51° 35' and 51° 53' N. lat. It is bounded on the north by the bishopric of Munster, and the province of Overysse, on the west by Brabant and Guelderland, on the south by part of Guelderland, the county of Mark, and the duchy of Berg, and on the east by the county of Reclinghausen and Munster. Since the year 1753 it has been divided into three circles, Cleves, Wesel, and Emmerid; Duisburg, Nanten, and Rees, are also districts of some note. In some parts the country is elevated, and covered with fields, woods and forests, sometimes three or four leagues in extent, on the borders of which are numerous towns and villages. The low grounds, especially on the banks of the Rhine, afford excellent pasturage and a great number of cattle and horses are reared in them. Corn, pulse, fruit, flax, tobacco and various vegetables are cultivated here. Game is abundant, and the rivers furnish salmon, pike, carp, and other fish in great numbers. This duchy contains twenty-four walled towns, the chief of which is

CLEVES, the ancient capital, situated on the river Kernisdale, more than two miles from the west bank of the Rhine. It is one of the neatest towns in the empire, standing in a pleasant situation on the declivity of a hill, and in a valley below it. It is built after the Dutch manner; but, though fortified, it is not very strong. In the upper part stands the castle of Schwanenburg, from which there is a beautiful prospect almost over the whole country. The side of the hill is formed into a number of terraces and alleys, which give it a beautiful appearance. This city is very ancient, having been known to the Romans, the traces of whose works are very evident in the country around. It contains about 5000 people, and is twelve miles south-east of Nimeguen, and seventy from Amsterdam; not far from the frontiers of the united provinces, to which it has a gate directly leading, called the gate of Holland. The duchy of Cleves belongs to the king of Prussia: it was indeed ceded to the French partly in 1792, and partly in 1806; and was then included in the department of the Roer. It was afterwards conferred by Buonaparte on general Murat; but, on the restoration of the states of Europe in 1815, it returned to its former possessor. It yields the king of Prussia a revenue of £200,000. The spinning of flax forms an important branch of industry in this country; woollen and linen cloths are also manufactured in several parts, and some silks. Its situation, lying along the Rhine, is extremely favorable for commerce, and the inhabitants are not backward in improving these advantages. The country people are mostly Catholics, while, in the towns, the Protestants form the greater proportion; there are also Jews and Mennonites, liberty of conscience being allowed to all sects. Before the French revolution there were many monasteries here; but they are now almost all suppressed. The air is salubrious, and the climate generally mild. The country is watered by several considerable streams besides the Rhine; as the Maese the Roer the Emeser. the Lippe,

and the Yssel. This duchy forms a part of the grand duchy of the Lower Rhine.

CLEVES, a town of Virginia, in the United States, two miles from Port Royal, in a northerly direction.

CLEW, *n. s.* Saxon, *clýpe*; Dutch, *klouwen*. Thread wound upon a bottom; a ball of thread. A guide; a direction; because men direct themselves by a clew of thread in a labyrinth.

Eftsoons untwisting his deceitful clew,
He gan to weave a web of wicked gnille.

Spenser.

While, guided by some clew of heavenly thread,
The perplexed labyrinth we backward tread.

Roscommon.

They see small *clews* draw vastest weights along,
Not in their bulk, but in their order, strong. *Dryden.*

When the only *clew* we have fails us, which is most reasonable, to stop short or to push forward, without any *clew* at all into the labyrinth of nature.

Bolingbroke.

This alphabet must be your own *clew* to guide you.

Holder.

Is there no way, no thought, no beam of light?
No *clew* to guide me through this gloomy maze,
To clear my honor, yet preserve my faith? *Smith.*

The reader knows not how to transport his thoughts over to the next particular, for want of some *clew*, or connecting idea to lay hold of. *Watt's Logic.*

Clew of the sail of a ship, is the lower corner of it, which reaches down to that earing where the tackles and sheets are fastened.

CLEW, *v. a.* From *clew*, a sea term. To *clew* the sails, is to raise them, in order to be furled; which is done by a rope fastened to the *clew* of a sail, called the *clew-garnet*.

CLIBADIUM, in botany, a genus of plants of the monœcia class and pentandria order. Male: *cal.* common and imbricated. Female florets three or four; *seed* an umbilicate drupe; species but one; a Surinam plant.

CLICK, *v. a.* } Dut. *cliken*; Fr. *cliqueter*;
CLICKER, *n. s.* } or perhaps the diminutive of
CLICKET, *n. s.* } clack. To make a sharp, small, successive noise. The substantives are two low words; one describes the servant of a salesman who calls to customers; the other, the knocker of a door.

The solemn death-watch *clicked*, the hour she died;
And shrilling crickets in the chimney cried. *Gay.*

CLIENT, *n. s.* } Lat. *cliens*. One
CLIENTED, *part. adv.* } who applies to an ad-
CLIENTSHIP, *n. s.* } vocate for counsel and defence. It may be perhaps sometimes used for a defendant in a more general sense.

I do think they are your friends and *clients*,
And fearful to disturb you. *Ben Jonson.*

There is due from the judge to the advocate some commendation, where causes are well handled; for that upholds in the *client* the reputation of his counsel.

Bacon's Essays.

Advocates must deal plainly with their *clients*, and tell the true state of their case.

Taylor's Rule of Living Holy.

This due occasion of discouragement, the worst conditioned and least *cliented* petivoguers do yet, under the sweet bait of revenge, convert to a more plentiful prosecution of actions.

Carew's Survey of Cornwall.

Patronage and *clientship* among the Romans always descended: the plebeian houses had recourse to the patrician line which had formerly protected them.

Dryden.

CLIENT, among the Romans, a citizen who put himself under the protection of some great man, who in respect of that relation was called patron. He assisted his client with his protection, interest, and goods; and the client gave his vote for his patron, when he sought any office for himself or friends. The right of patronage was appointed by Romulus, to unite the rich and poor together, in such a manner as that one might live without contempt, and the other without envy; but the condition of a client, in course of time, became little else but a moderate slavery.

CLIFF, *n. s.* Lat. *clivus*; Sax. *clip*, *clöp*. A steep rock; a rock, according to Skinner, broken and craggy (*rupes*). The name of a character in music, properly *cléf*.

This ladie rometh by the *cliffe* to plaie,
With her meine, endlong upon the stronde;
And findeth Jason, and this other stonde,
In speking of this thing, as I you told.

Chaucer. Legend.

The Leucadians did use to precipitate a man from a high *cliff* into the sea.

Bacon's Nat. Hist.

Mountainers, that from Severus came,
And from the craggy *cliffs* of Tetrica. *Dryden.*

Wherever 'tis so found scattered upon the shores,
there is it as constantly found lodged in the *cliffs* threabout. *Woodward.*

CLIFFORD (George), earl of Cumberland, a nobleman distinguished for his naval enterprises, was born in Westmoreland, in 1558, and educated at Peter-house in Cambridge, under Dr. Whitgift, afterwards archbishop of Canterbury. He was particularly attentive to the study of the mathematics. He was also noted for his skill in the tournament, and all the martial exercises of his age. Queen Elizabeth, on one occasion, took off her glove and gave it to him; a mark of royal favor, which, on public occasions, he used to wear in his hat, adorned with diamonds. In 1586 he fitted out a small squadron, with which he sailed for South America, and, after taking several vessels from the Portuguese, returned to England. In 1588 he took the command of a ship, with which he contributed greatly to the destruction of the Spanish armada; and was rewarded for his gallant conduct by a grant from the queen of a commission to make another voyage to the South Sea. In this, however, he was unfortunate, for, after proceeding as far as the Azores, he was obliged by tempestuous weather to return; nor was he more successful in 1591, in an expedition to the coast of Spain. Yet he next year attacked the Azores, and took the town of Santa Cruz and a rich galleon, valued at £150,000. He sailed again in 1593 and took several very valuable Spanish prizes. In 1595 he fitted out a ship of 900 tons burden, being the largest that had ever been launched by an English subject, but was prevented, by an order from the queen, from sailing in it himself. In three years after, however, he sailed with a squadron to the West Indies, where he took the island of Porto Rico; but in this voyage a great number of his men were carried off by sickness. This

intrepid nobleman died at Savoy, in 1605, and his remains were interred at Skipton in Yorkshire.

CLIFFORD (Anne), only daughter of the above, born in 1589 at Skepton castle, Craven, and was twice married: first to Richard lord Buckhurst, afterwards earl of Dorset, whose life she wrote, and brought him three sons and two daughters. Her second husband was Phillip earl of Pembroke. She built in the course of her life two hospitals, and erected or repaired seven churches. She also erected monuments to the poets Spenser and Daniels, the latter being her tutor. She is particularly celebrated for a spirited reply to Sir Joseph Williamson, secretary of state, after the Restoration. He had presumed to nominate a candidate for *her* borough of Appleby: 'I have been bullied,' said she, 'by an usurper; I have been neglected by a court; but I will not be dictated to by a subject; your man sha'n't stand.'

CLIFFORTIA, in botany, a genus of the polyandria order, and diœcia class of plants; natural order thirty-eighth, tricoœca: male CAL. triphyllous; COR. none; the stamina near thirty in number: female CAL. triphyllous, superior to the receptacle; styles two; CAPS. bilocular; SEED single: species nineteen, all natives of Africa. Their flowers make no very handsome appearance; but the plants themselves are very ornamental evergreens. They grow to the height of four or five feet, and are propagated by cuttings, which must be young shoots of five or six inches long. If planted in pots in spring or summer, and plunged in a hot-bed, they will readily take root. They must be watered plentifully in summer, but very sparingly in winter.

CLIFT, *n. s.* The same with cliff, now disused.

Down he tumbled, like an aged tree,
High growing on the top of rocky *clift*. *Spenser.*
Lo! where the stripling wrapt in wonder roves,
Beneath the precipice o'erhung with pine;
And sees on high, amidst the encircling groves,
From *clift* to *clift* the foaming torrents shine.
Beattie.

CLIFTON, a parish of Gloucestershire, one mile west from Bristol, and 114 west from London. It stands on a cliff or hill, rising gradually from the river Avon, and has been termed, from the salubrity of its air, the Montpellier of England. Within a few years this beautiful village has been adorned with new and elegant ranges of buildings, shooting out, as a physician phrases it, almost with the rapidity of crystallisation. They are occupied generally by those who seek the aid of the Bristol waters; or very respectable constant residents. It has a most charming prospect of the river, and of the western part of Bristol. The church is handsome and commodious, and on the downs are the remains of Roman military works. Inhabitants about 9000.

CLIMACTER, *n. s.* } Gr. κλιμακτηρ. A
CLIMACTERIC, *adj.* } certain space of time,
CLIMACTERICAL, *adj.* } or progression of years,
which is supposed to end in a critical and dangerous time, at the end of which some change is supposed to befall the body.

Elder times, settling their conceits upon *climacters*, differ from one another. *Broune's Vulgar Errors.*

Certain observable years are supposed to be attended with some considerable change in the body; as the seventh year; the twenty-first, made up of three times seven; the forty-ninth, made up seven times seven; the sixty-third, being nine times seven; and the eighty-first, which is nine times nine; which two last are called the grand *climactericks*. *Id*

The numbers seven and nine, multiplied into themselves, do make up sixty-three, commonly esteemed the great *climacterical* of our lives. *Id.*

Your lordship being now arrived at your great *climacterique*, yet give no proof of the least decay of your excellent judgment and comprehension. *Dryden.*

My mother is something better, though, at her advanced age, every day is a *climacterick*. *Pope.*

CLIMATE, *v. n. & n. s.* } Gr. κλιμα. A
CLIMATURE, *n. s.* } space upon the surface of the earth, measured from the equator to the polar circles. Also a region, or tract of land, differing from another by the temperature of the air.

The blessed gods
Purge all infection from our air, whilst you
Do *climate* here. *Shakspeare.*

Such harbingers preceding still the fates,
Have heaven and earth together demonstrated
Unto our *climates* and countrymen. *Id.*

Betwixt the extremes, two happier *climates* hold,
The temper that partakes of hot and cold. *Dryden.*

On what new happy *climate* are we thrown. *Id.*
This talent of moving the passions cannot be of any great use in the northern *climates*. *Swift.*

The subject of *climate* should be studied and attentively observed by the architect; and particularly the effects of the vicissitudes of the seasons upon its materials. *Elmes' Dictionary.*

CLIMATE, in geography, expresses: 1. A portion of the earth's surface contained between two circles parallel to the equator, and of such a breadth, as that the longest day in the parallel nearest the pole exceeds the longest day in that nearest the equator by some certain space of time; and 2. The ordinary state of the atmosphere, with regard to heat and moisture, which prevails in any given portion of the globe. Abulfeda, the great Arabian geographer, gave the names of *real* and *apparent* climates to these two acceptations of the word.

I. In the former the original acceptation of the word is traced, as we see, to the Greek word κλιμα, κλινω, to incline; and was intended by the ancients to express the obliquity of the sphere with respect to the horizon, the causes of the inequalities of day and night. Ptolemy divided the earth's surface from the equator to the arctic circle into zones calculated to make an increase of a quarter of an hour each in the longest day. These zones would be, of course, nearly of equal breadth near the equatorial line, and become contracted in higher latitudes. It was judged, therefore, sufficient to estimate them in those latitudes by their doubles answering to half an hour's increase of time at Midsummer. The late professor Leslie furnishes, from Ptolemy's geographical work, the following table of the climates as he calculated them.

TABLE OF THE CLIMATES.

Climate, or Parallel.	Latitude.	Length of Midsummer day.	Breadth of zone.	Climate, or Parallel.	Latitude.	Length of Midsummer day.	Breadth of zone.
I.	0° 0	12h. 00m	4° 15'	XIV.	43° 4m	15h. 15'	1° 57'
II.	4 15	12 15	4 10	XV.	45 1	15 30	1 50
III.	8 25	12 30	4 5	XVI.	46 51	15 45	1 41
IV.	12 30	12 45	3 57	XVII.	48 32	16 00	1 32
V.	16 27	13 00	3 47	XVIII.	50 4	16 15	1 36
VI.	20 15	13 15	3 38	XIX.	51 40	16 30	1 10
VII.	23 51	13 30	3 21	XX.	52 50	16 45	1 40
VIII.	27 12	13 45	3 10	XXI.	54 30	17 00	1 30

Varenius gives us a table of thirty ancient climates; but without any regard to the refractions. Ricciolus furnishes a more accurate one, wherein the refractions are allowed for; an abstract of which follows:—

Middle of Climate.	Longest Day.	Lat.	Middle of Climate.	Longest Day.	Lat.	Middle of Climate.	Lat.	Cont. Light.	North Night.	Cont. Light.	South Night.
I.	12h 30'	7° 18'	VIII.	16th 0	48° 15'	XV.	66° 53'	31d	27d	30d	28d
II.	13 01 36		IX.	17 0	53 46	XVI.	69 30	62	58	60	59
III.	13 30 23 8		X.	18 0	57 44	XVII.	73 0	93	87	89	88
IV.	14 0 29 49		XI.	19 0	60 39	XVIII.	78 6	124	117	120	118
V.	14 30 35 35		XII.	20 0	62 41	XIX.	84 0	156	148	150	149

VII.	15 30 44 42		XIV.	24 0	65 54						

More ancient writers speak of seven climates only, confining them to what they imagined the habitable part of the earth. The first they made to pass through Meroe, the second through Sienna, the third through Alexandria, the fourth through Rhodes, the fifth through Rome, the sixth through Pontus, and the seventh through the mouth of Borysthenes.

The beginning of the climate is a parallel circle wherein the day is the shortest. The end of the climate is that wherein the day is the longest; the climates being reckoned, as we have stated, from the equator to the pole. The first, at its beginning, has its longest day precisely twelve hours long; at its end twelve hours and a half; the second, which begins where the first ends, viz. at twelve hours and a half, ends at thirteen hours; and so of the rest, as far as the polar circles, where, what the geographers call hour climates terminate, and month climates commence. As an hour climate is a space comprised between two parallels of the equator, in the first of which the longest day exceeds that in the latter by half an hour; so the month climate is a space terminated between two circles parallel to the polar circles, whose longest day is longer or shorter than that of its contiguous one by a month or thirty days.

The breadth of the respective climates is found

by adding the logarithmic cotangent of the sun's greatest declination to the logarithmic sine of his ascensional difference; the sum of these logarithms being the logarithmic tangent of the latitude of the circle nearest the pole; which, being given in each, will determine, of course, the whole operation of forming these circles. Those between the polar circles and the poles are determined by the sun's declination.

The following tables contain the latitude where each climate ends, the length of the longest day at its termination, and its breadth, in degrees and minutes, from Mr. Myer's very complete System of Geography.

FROM THE POLAR CIRCLES TO THE POLES.

Climate.	End of Climate.	Length of Day.	Breadth of Climate.
		Days.	
1	67° 18'	30	0° 46'

II Under the second, and more modern acceptation of the word climate, we have to notice the leading features of that great variety of condition and temperature, which pervades the atmosphere of the globe in different regions.

These have been sometimes treated under four very obvious divisions. The cold and humid; cold and dry; warm and humid; hot and dry. 1. A cold and humid climate is such as pervades the eastern shores of Canada, Newfoundland, and Siberia, where the atmosphere, loaded with fogs, yields little encouragement to settlers, and the few vegetable productions only seem to increase the general gloominess of the scene, being confined to a few hardy shrubs. The fenny districts of more temperate regions, as those of some parts of the eastern shores of England, partake of this climate in a modified degree. 2. A cold and dry climate prevails in most of the northern countries of Europe and Asia, in the winters of Upper Canada, &c. and this seems not to be inimical even to delicate human constitutions, while the finest streams of water and abundant vegetation attend it. 3. Warm and humid climates pervade large districts of both the Old and New Worlds; as, Guinea, Demerara, Panama; Hindostan, particularly Bengal, Zanguebar, and Senegal. Here vegetation luxuriates, and is, at the same time, vigorous; the verdant plains are diversified by gigantic trees; and, while the miasmatic vapors render the atmosphere un congenial to man, the noblest and most ferocious of animals, reptiles of immense size, and beautiful specimens of the feathered creation abound. 4. Hot and dry climates are those of the African and Arabian deserts, where plants, animals, and man, alike languish under burning suns, water is evaporated, and the earth is sand, or 'iron, and the heavens brass.'

These four climates do not, however, as Mr.

Myers observes, always exist according to the full import of the terms by which they are designated. They are subject to various modifications, particularly of two distinct kinds. The one results from the alternation of two different climates in the same region: the other, from the greater or less prevalence of either of the four elements. Thus, when heat, dryness, and humidity are duly combined, they render the climate comparatively temperate. In Egypt, for instance, the combinations of heat and humidity, during the inundation of the Nile, and of heat and dryness during the rest of the year, temper a climate, which, without these alternations, would be insupportable. In Holland the cold humidity of the autumn is succeeded by frost, which increases the salubrity of the climate, that would otherwise not be so healthy. In some places, however, the changes take place so rapidly, or the difference of temperature is so great, that it renders the climate more pernicious to the constitution, than though only one of the kinds existed. The inhabitants of Astrachan and some other cities experience the heats of Africa in summer, and the colds of Siberia in winter. The same constitution of the atmosphere is also agreeably modified, in some instances, by the solar heat; for the dry heat which renders the great desert of Sahara almost inaccessible, becomes a pleasant temperature at either Madrid or Marseilles. The fatal effects of humid heat are less powerful as we advance from the equator; and on the contrary the cold, either dry or humid, is more supportable as we quit the depths of the polar regions and approach towards the tropics. Bergen and Brest have the same winter constitution of the atmosphere, which is rendered humid and varied by the contiguity of the western ocean, but the annual temperatures of the two places are widely different.

The varieties of season connected with this question, we cannot enter into in this place; further than to observe, that in the torrid zone the winter is generally a wet, the summer a dry, season; and that this constitutes the great division of their year: but these are in direct opposition to those seasons, as they would result from the position of the sun in the ecliptic. 'The rain always accompanies the sun, so that, when this luminary is in the northern signs of the zodiac, the countries on that side of the equator have their rainy season. The vertical rays of the sun continually rarify the atmosphere in these regions, the air of colder districts rushes in to restore the equilibrium, the vapors become condensed, and a deluge of rain is the consequence. Those parts of the torrid zone, where there is scarcely any evaporation, have no rain; and in other places the mountains so modify the monsoons as to produce two rainy seasons in the year.' See SEASON.

Professor Leslie insists that all the varieties of climate are reducible to these two causes—distance from the equator,—and height above the level of the sea. 'Latitude and local elevation form, indeed,' says he, 'the great bases of the law of Climate, and any other modifications have only a partial and very limited influence.'

The most obvious effects of latitude appear, in the degree of obliquity given to the solar rays, as

they fall on the surface of the earth, and the quantum of space through which they pass in reaching its surface. Each of these are the immediate results, of course, of the relative height of the sun, and may be illustrated by the following diagram:—

A b B represents the hemisphere, and the dotted semicircle *C D* the upper limit of the atmosphere; *E a* and *E b* are the extreme rays of a pencil of light falling upon the earth at *a* and *b*. And *E' a* and *E' c*, the extreme rays of an equal pencil, when the sun has a less elevation, as at the winter solstice. It will be evident that the rays reach the surface of the earth in a much more attenuated state in the one case than in the other; and that, as the number of rays in the two pencils is the same, their density will be inversely as the areas of the elliptic spaces they cover. These are as the transverse axes *a b*, *a' c*, since the two conjugate axes are equal. The pencil *E' a* has also a much greater space to pass through the terrestrial atmosphere, than *E a*, by which its influence is still further weakened. These causes unite, therefore, in diminishing the solar influence, as the altitude of that luminary decreases; and as this altitude is greatest at the equator, where the sun is vertical, and decreases as the latitude increases, the propriety of the appellations given to the different zones becomes evident, as well as the effects which such a circumstance must have upon the general temperature of the different regions upon which the sun shines.

But, in addition to what we call the height of the sun, the distance of that luminary from the earth must always be taken into consideration in the estimate of different climates. The ratio of these distances at the summer and winter solstices is nearly as 30 to 29; and the number of rays that fall on the same space are inversely as the squares of these distances; and, consequently, in this case, as 900 to 841.—Hence the solar influence in winter is to that in summer, in reference to the distance of the sun only, as 900 to 841, or very nearly as 1.0702 to 1. The length of the day, or the continuation of the sun above the horizon, certainly increases the heat of particular regions, as the shortness of the night also affords less time for a dispersion of the heat accumulated. Refraction and reflection also modify the action of the sun's rays. M. Bouguer has calculated that of 10,000 rays which fall perpendicularly upon the atmosphere, only 8123 reach the surface of the earth; and, if their angle of incidence be 50°, not more than 7624 fall on its surface; that the number was reduced to 2031 when the angle was 7°; and to

5° only when the direction was horizontal. And the earth itself, as absorbing a number of these rays and returning them to the air by reflection, becomes a great source of heat; distance from the earth must therefore be a source of cold; thus we find that, as you ascend in the atmosphere, the cold increases. In the vicinity of Paris, the temperature of the earth being 47°, at the estimated height of 11,084 feet it was found to be 21°, or 11° below congelation, by M. Charles, who ascended in a balloon. And lord Mulgrave, at the bottom of Hackluyt-hill, lat. 80°, found the temperature of the air 50°; but on the top, at the height of 1503 feet, only 42°. Hence we find, that the highest mountains, even under the equator, have their tops continually covered with snow. M. Bouguer found the cold of Pinchina, one of the Cordelieres, immediately under the line, to extend from 7° to 9° below the freezing point every morning before sun-rise; and hence at a certain height, which varies in almost every latitude, it constantly freezes at night all the year round, though in the warm climates it thaws in the same degree the next day. This height M. Bouguer calls the lower term of congelation; between the tropics he places it at the height of 15,577 feet, English measure. And thus while the base of these mountains rests on burning sand, about half way up, in the plains of Quito, we found a temperate zone of the most delightful character. As the hot winds from below ascend the sides of the mountains, they become so cooled by the expansion of the air, that they do not affect the snow on the summits; and the cold winds which sweep over their snowy crests, and descend to the lower regions, are condensed as they proceed, and acquire a temperate warmth before they reach these fertile plains.

A great source of cold is evaporation. The same cause which makes the condensation of vapor a source of heat, makes evaporation the source of cold; as it absorbs the fire in the latter instance, which it gives out in the former: the heat thus absorbed is called latent heat; it producing, in that state, no sensation of warmth. At a certain height above the lower term of congelation it never freezes, not because the cold decreases, but because the vapors do not ascend so high; this height M. Bouguer calls the upper term of congelation, and under the equator he fixes it at the height of 28,000 feet. Kirwan has given us the following mean height of the upper and lower terms of congelation, for the latitude of every 5°, in feet.

Lat.	Alt. lower Term.	Alt. upper Term.	Lat.	Alt. lower Term.	Alt. upper Term.
0°	15,577	28,000	45	7,658	13,730
5	15,457	27,784	50	6,260	11,253
10	15,067	27,084	55	4,912	8,330
15	14,498	26,061	60	3,684	6,546
20	13,719	24,661	65	2,516	4,676
25	13,020	23,423	70	1,557	2,809
30	11,592	20,836	75	748	1,346
35	10,664	19,169	80	120	207
40	9,016	16,207			

Sometimes the temperature of the upper air is higher than that of the lower air, particularly when a large mass of vapors is condensed by electrical agency; for no part of the heat given out by that cause being lost by communication with air much colder, that which surrounds the vapors so condensed, must be heated to a considerable degree. The clouds, by absorbing the sun's rays, are more heated than the clear air would be. These, and other circumstances, render the true height of the terms of congelation, at any time, subject to considerable uncertainty.

Of evaporation, the following facts may be observed: 1. That, in our climates, evaporation is about four times as great from the 21st of March to the 21st of September, as from the 21st of September to the 21st of March. 2. That, other circumstances being the same, it is greater in proportion as the difference between the temperature of the air, and that of the evaporating surface is greater; and so much the smaller, as the difference is smaller; and therefore smallest, when the temperature of the air and evaporating liquor are equal. The former part of this proposition however requires some restriction; for, if air be more than 15° colder than the evaporating surface, there is scarcely any evaporation; but, on the contrary, it deposits its moisture on the surface of the liquor. 3. The degree of cold produced by evaporation is always much greater when the air is warmer than the evaporating surface, than that which is produced when the surface is warmer than the air. Hence, warm winds, as the Sirocco and Harmatan, are more drying than cold winds. 4. Evaporation is more copious when the air is less loaded with vapors, and is therefore greatly promoted by cold winds flowing into warmer countries. 5. Evaporation is greatly increased by a current of air or wind flowing over the evaporating surface, because unsaturated air is constantly brought into contact with it. Hence, calm days are hottest, as has commonly been remarked. 6. Tracts of land covered with trees or vegetables emit more vapor than the same space covered with water. Mr. Williams (*Philadelphia Transactions*) found this quantity to amount to one-third more. Hence, the air about a wood or forest is made colder by evaporation from trees and shrubs, while the plants themselves are kept in a more moderate heat, and secured from the burning heat of the sun, by the vapors perspired from the leaves. Thus, we find the shade of vegetables more effectual to cool us, as well as more agreeable, than the shade from rocks and buildings: and from the same cause the clearing away of woods lessens the vapors, and consequently diminishes the quantity of rain, and increases the temperature. Several parishes in Jamaica which used to produce fine crops of sugar canes, are now dry for nine months in a year, and are turned into cattle-pens through the clearing away of the woods. Hence again, water is most plentiful in those countries where woods abound, and the best springs are there found. Since the woods in the neighbourhood of the American towns have been cut down, many streams have become dry; and others have been reduced so low, as to

cause great interruptions to the miller. It appears probable, that the climates of European countries were more severe in ancient times than they are at present. Cæsar says, that the vine could not be cultivated in Gaul, on account of its winter-cold. The rein-deer, now found only in the zone of Lapland, was then an inhabitant of the Pyrenees. The Tiber was frequently frozen over, and the ground about Rome covered with snow for several weeks together, which very rarely happens in our times. The Rhine and the Danube, in the reign of Augustus, were generally frozen over for several months of winter. The barbarians who overran the Roman empire a few centuries afterwards, transported their armies and waggons across the ice of these rivers.

Drainage of the ground, and removal of forests, however, cannot be reckoned among the sources of the increased warmth of the Italian winters. Chemical writers, says Dr. Ure, have omitted to notice an astronomical cause of the progressive amelioration of the climates of the northern hemisphere. In consequence of the apogee portion of the terrestrial orbit being contained between our vernal and autumnal equinox, our summer half of the year, or the interval which elapses between the sun's crossing the equator in spring, and in autumn, is about seven days longer than our winter half year. Hence, also, one reason for the relative coldness of the southern hemisphere.

In the article CLIMATE (Supplement to the Encyclopædia Britannica) the following simple rule is given for determining the change of temperature produced by sudden *rarefaction*, or condensation of air. Multiply 25 by the difference between the density of air and its reciprocal, the product will be the difference of temperature on the centigrade scale. Thus, if the density be twice, or one half $25 \times (2 - \frac{1}{2}) = 37\frac{1}{2}$ cent. = 67.5° Fahrenheit, indicates the change of temperature by doubling the density or rarity of air. Were it condensed thirty times, then, by this formula, we have 749° for the elevation of temperature, or $25^{\circ} (30 - \frac{1}{30})$. But M. Gay Lussac says, that a condensation of air into one-fifth of its volume is sufficient to ignite tinder; a degree of heat which he states at 300° centigrade = 572 Fahrenheit (*Journal of Science*, vol. vii. p. 177). This experimental result is incompatible with professor Leslie's formula, which gives only 112.5° for the heat produced by a condensation into one-fifth.

The sea exercises an important equalising influence on the temperature of the globe. In the tropical regions a large extent of ocean spreads coolness on every side, and affords a perpetual succession of refreshing breezes. Islands are always, comparatively, of more temperate climates than continents, and those scattered over the expanse of the Pacific, may be said to enjoy almost a perpetual spring. The districts which are surrounded on every side by tracts of continent, experience no mitigation of heat, and are often utterly consumed by the droughts of summer: insular tracts also, and those situated along the sea-coast, experience much less rigorous winters than the interior of continents. The greatest cold in our hemisphere is said to occur

when any country has a wide extent of sea to the south, and of land to the north. Thus Greenland, in lat. 60°, exhibits a more rigorous climate than Lapland, in lat. 72°. From the like cause, the north-east extremity of Asia suffers a cold almost equally intense; and the same combination of circumstances renders the climate of North America, under the same parallel, much colder than that of Europe.

Nor is the influence of *winds* in general, and the trade-winds in particular, here to be forgotten. Blowing from east to west across the sands of Africa, the latter produce, on its western coast, a most intense heat, much greater than is experienced on the eastern. In passing the Atlantic, they are considerably cooled; and though, in traversing South America, their temperature is again raised, yet, before reaching the opposite coast, they meet the tremendous snow-clad Andes, which stop their progress, and diffuse a wide coolness.

Again, the mountain ranges of the earth not only present and retain on their sides a refreshing coolness; but, by the mighty rivers to which they give rise, diffuse a great amelioration of the temperature through extensive regions. They are particularly of this character, and give rise to the largest rivers in the torrid and burning climes of the earth. In the temperate climates, and those approaching to the poles, mountains are of moderate elevation, are almost always barren, and give rise to few considerable streams.

Professor Mayer, from a comparison of observations, constructed the following empirical rule for finding the relation between the latitude and the mean temperature, in centesimal degrees, at the level of the sea. Multiply the square of the cosine of the latitude by the constant number 29, the product is the temperature. The variation of temperature for each degree of latitude is hence denoted centesimally with very great precision, by half the sine of double the latitude.

Latitude.	Mean temperatures.		Height of curve of congelation in feet.
	Cent.	Fahr.	
0°	20°	84·2	15207
5	28·78	83·8	15095
10	28·13	82·6	14764

85	0·22	32·4	117
90	0·0	32·0	00

As the heat is uniformly greater approaching the equator from the poles, it might be supposed

that the annual accumulation would increase the average temperature of those regions. But this is not the case. The perpetual motion and currents of the atmosphere preserve a maximum temperature, which is but little varied; for, as the air of the equatorial regions becomes warmer, the northern winds have the greater tendency to rush in upon it with rapidity, and check the excess.

‘But within the arctic circle,’ observes an intelligent writer, ‘another powerful agent of nature is constantly tempering the inequality of the seasons. The vast beds of snow, or fields of ice which cover the land and sea in these dreary retreats, absorb, in the act of thawing or passing again into their liquid form, all the surplus heat collected during a nightless summer. The rigor of winter, when darkness resumes her tedious reign, is likewise mitigated by the warmth evolved as congelation spreads over the watery surface.’

Experiments have been made, both at home and abroad, to ascertain the comparative temperature of the earth below its surface, as compared with that of the atmosphere; and they have differed very little.

‘In the caves below the observatory at Paris, in 49° of north latitude, and about eighty-five feet below the surface, Fahrenheit’s thermometer constantly stands between 52° and 54°, and scarcely ever varies 2°; while at the surface the difference of temperature, between summer and winter, sometimes exceeds 90°. In the salt mines at Wieliczka, near 50° of latitude, from the depth of 320 to that of 745 feet, the thermometer stands at about 50°. At Cairo, in Egypt, latitude 30°, at the bottom of Joseph’s well, the depth of which exceeds 210 feet, the thermometer stands at 70°. In the mines of Mexico, at 20° of latitude, the temperature at the depth of 1650 feet, was 74°; thus it augments in approaching the equator.’—*Lacroix’s Geo. Physique*.

Mr. Leslie reports some very interesting experiments on this subject, made in the garden of his friend, Robert Ferguson, esq. of Abbots-hall, in a gravelly soil, lat. 56° 10’, and proving how slow is the transmission of heat through the body of the earth. The thermometers were sunk to the depth of one, two, four, and eight feet, and the transmission from the surface appears to have been about an inch per day. The first of these thermometers never sunk lower than 33°, and indicated a mean temperature of 45°·5, which shows that the frost seldom penetrates to that depth. The nature of the soil, however, and external circumstances, must have a great influence on this penetration, as has been proved by experiment. In the same paper it is stated that, ‘in the neighbourhood of Edinburgh, after a long continuance of rigorous weather, the frost was found to have penetrated thirteen inches into the ground in a ploughed field, but only eight inches in one piece of pasture ground, and four inches in another. But, in some of the streets of that city, the frost had descended even below two feet, so as to begin to affect the water-pipes. The greater density and solidity of the pavement had no doubt conducted the frigorific impressions more copiously downwards, while

the loose and spongy blades of grass had mostly scattered and wasted these impressions in the open field. This consideration, it is obvious, might lead to very important practical results. The mean temperatures indicated by the thermometers, at the depth of four and eight feet, were $46\frac{1}{2}^{\circ}$ and $46\frac{1}{4}^{\circ}$; and the mean annual ranges of

the four, in their order from the surface, were, 25° , 20° , 15° , and $9\frac{1}{2}^{\circ}$. The smaller annual temperature of the upper thermometers, the writer thinks, is satisfactorily accounted for by the coldness of the summers of 1816 and 1817, especially the former. The result of the whole number of experiments was as follows:—

	1816.				1817.			
	1 foot.	2 feet.	3 feet.	4 feet.	1 foot.	2 feet.	3 feet.	4 feet.

On this subject, Mr. Leslie remarks, that, ' If the thermometer had been sunk considerably deeper, they would, no doubt, have indicated a mean temperature of $47\cdot7^{\circ}$. Such is the permanent temperature of a copious spring which flows at a short distance, and about the same elevation, from the side of a basaltic, or green-stone rock. Profuse fountains and deep wells, which are fed by percolation through the crevices of the strata, furnish the surest and easiest mensuration of the temperature of the earth's crust. The body of water which bursts from the caverns of Vaucluse, and forms almost immediately a respectable and translucent river, has been observed not to vary in its temperature, by the tenth part of a degree (centigrade) through all the seasons of the year. It is therefore an object highly important for scientific travellers, to notice the precise heat of springs in favorable situations, as they issue from their rocky beds. Such choice observations would accurately fix the medium temperature of the climate. It is only requisite to exclude the superficial and the thermal springs, which are not difficult to distinguish.' See the article CLIMATE. *Supplement to the Encyclopædia Britannica.*

The mean temperature of the air, near the surface of the earth, has also been ascertained at various places. At Paris and Cairo it was found to correspond nearly with the numbers before stated. At St. Petersburg in lat. 60° the mean temperature is about 39° . At Wadso, in Lapland, in 70° of latitude, it was found to be about 36° ; and in the island of Mageröe, near the North Cape, the mean temperature of the year is stated, by M. Von Buch, to be nearly 32° ; the mean for every month in the same situation, is inserted at page 312 of this volume. According

to M. Humboldt, the hottest places are on the southern shores of the Caribbean sea, and the gulf of Guayaquil, in the great equinoxial ocean, between two and three degrees of south latitude. There the mean heat is $81\cdot5^{\circ}$; and the thermometer sometimes rises to 106° . At Belbeis, in Egypt, the thermometer has risen to more than 125° in the shade; but this was occasioned by the hot wind, denominated Sirocco. At St. Petersburg, on the contrary, the cold is sometimes so intense as to congeal mercury. It has also been observed, at the same place, to rise above 90° .

In the first number of the Edinburgh Philosophical Journal, some facts are stated by Mr. Bald apparently incompatible with the idea of the interior temperature of the earth being deducible from the latitude of the place, or the mean temperature at the surface.

The following table presents at one view the temperature of air and water in the deepest coal-mines in Great Britain.

Whitehaven Colliery, county of Cumberland.

	Degrees Fah.
Air at the surface	55
A spring at the surface	49
Water at the depth of 480 feet	60
Air at the same depth	63
Air at depth of 600 feet	66
Difference between water at surface and at 480 feet	11

Workington Colliery, county of Cumberland.

Air at the surface	56
A spring at the surface	48
Water 180 feet down	50

	Degrees Fah.
Water 504 feet under the level of the ocean, and immediately beneath the Irish Sea	60
Difference between water at surface and bottom	12
<i>Tem Collicry, county of Durham.</i>	
Air at pit bottom, 444 feet deep	68
Water at same depth	61
Difference between the mean temperature of water at surface = 49°, and 444 feet down	12
<i>Percy Main Collicry, county of Northumberland.</i>	
Air at the surface	42
Water about 900 feet deeper than the level of the sea, and under the bed of the river Tyne	68
Air at the same depth	70
At this depth Leslie's hygrometer indicated dryness = 83°.	
Difference between mean temperature of water at surface = 49°, and at 900 feet down	19
<i>Jarrow Collicry, county of Durham.</i>	
Air at the surface	49
Water 882 feet down	68
Air at same depth	70
Air at pit bottom	64
Difference between the mean temperature of water at surface = 49°, and 882 feet down	19
The engine pit of Jarrow is the deepest perpendicular shaft in Great Britain, being 900 feet to the foot of the pumps.	
<i>Killingworth Collicry, county of Northumberland.</i>	
Air at the surface	48
Air at bottom of pit, 790 feet down	51
Air at depth of 900 feet from the surface, after having traversed a mile and a half from the bottom of the downcast pit	70
Water at the most distant forehead or mine, and at the great depth of 1200 feet from the surface	74
Air at the same depth	77
Difference between the mean temperature of the water at the surface = 49°, and water at the depth of 1200 feet	25
Distilled water boils at this depth at	213
Do. do. at surface	210½

Saussure found the lake of Geneva, at the depth of 1000 feet, to be 42°; and below 160 feet from the surface there is no monthly variation of temperature. The lake of Thun, at 370 of depth, and Lucerne at 640, had both a temperature of 41°, while the waters at the surface indicated respectively 64° and 68° 30' Fah. Barlocchi observed, that the Lago Sabatino, near Rome, at the depth of 490 feet, was only 44° 30', while the thermometer stood on its surface at 77°. Mr. Jardine has made accurate observations on the temperatures of some of the Scottish lakes, by which it appears, that the temperature continues uniform all the year round, about twenty fathoms under the surface. In like manner, the mine of Dannemora in Sweden, which

presents an immense excavation, 200 or 300 feet deep, was observed, at a period when the working was stopped, to have great blocks of ice lying at the bottom of it. The bottom of the main shaft of the silver mine of Kongsberg in Norway, about 300 feet deep, is covered with perpetual snow. Hence, likewise, in the deep crevices of Atna and the Pyrenees, the snows are preserved all the year round. It is only, however, in such confined situations that the lower strata of air are thus permanently cold. In a free atmosphere the gradation of temperature is reversed, or the upper regions are colder, in consequence of the increased capacity for heat of the air, by the diminution of the density. In the milder climates it will be sufficiently accurate, in moderate elevations, to reckon an ascent of 540 feet for each centesimal degree, or 100 yards for each degree on Fahrenheit's scale of diminished temperature. Dr. Francis Buchanan found a spring at Chitlong, in the lesser valley of Nepaul, in Upper India, which indicated the temperature of 14·7 centesimal degrees, which is 31° below the standard for its parallel of latitude, 27° 38'. Whence, $8\cdot1 \times 540 = 4374$ feet is the elevation of that valley. At the height of a mile this rule would give about thirty-three feet too much. The decrements of temperature augment in an accelerated progression as we ascend.

Ben Nevis, the highest mountain in Great Britain, stands in latitude 57°, where the curve of congelation reaches to 4534 feet. But the altitude of the summit of the mountain is no more than 4380 feet; and therefore, during two or three weeks in July, the snow disappears. The curve of congelation must evidently rise higher in summer, and sink lower in winter, producing a zone of fluctuating ice, in which the glaciers are formed.

Baron Humboldt has stated, that the temperature of the silver mine of Valenciana in New Spain is 11° above the mean temperature of Jamaica and Pondicherry, and that this temperature is not owing to the miners and their lights, but to local and geological causes. To the same local and geological causes we must ascribe the extraordinary elevation of temperature observed by Mr. Bald. He further remarks that the deeper we descend, the drier we find the strata; so that the roads through the mines require to be watered, in order to prevent the horse-drivers from being annoyed by the dust. This fact is adverse to the hypothesis of the heat proceeding from the chemical action of water on the strata of coal. As for the pyrites intermixed with these strata, it does not seem to be ever decomposed, while it is in situ. The perpetual circulation of air for the respiration of the miners must prevent the lights from having any considerable influence on the temperature of the mines.

M. Humboldt has also published an admirable systematic view of the mean temperatures of different places, in the third volume of the Memoirs of the Society of Arceuel. His paper is entitled, Of Isothermal Lines (lines of the same temperature), and the distribution of Heat over the Globe. By comparing a great number of observations made between 46° and 48° N. lat., he

found, that at the hour of sun-set the temperature is, very nearly, the mean of that at sun-rise and two hours after noon. Upon the whole, however, he thinks that the two observations of the extreme temperatures will give us more correct results.

The difference which we observe in cultivated plants, depends less upon mean temperature, than upon direct light, and the serenity of the atmosphere; but wheat will not ripen if the mean temperature descend to 47°6'.

Europe may be regarded, according to this distinguished traveller, as the western part of a great continent, and subject to all those influences which make the western sides of all the continents warmer than the eastern. The same difference that we observe on the two sides of the Atlantic, exists on the two sides of the Pacific. In the north of China the extremes of the seasons are much more felt than in the same latitudes in New California, and at the mouth of the Columbia. On the eastern side of North America, we have the same extremes as in China;

New York has the summer of Rome, and the winter of Copenhagen; Quebec has the summer of Paris, and the winter of Petersburg. And in the same way in Pekin, which has the mean temperature of Britain, the heats of summer are greater than those at Cairo, and the cold of winter as severe as that at Upsal. This analogy between the eastern coasts of Asia and of America, sufficiently proves, that the inequalities of the seasons depend upon the prolongation and enlargement of the continents towards the pole, and upon the frequency of north-west winds, and not upon the proximity of any elevated tracts of country.

Ireland, according to Humboldt, presents one of the most remarkable examples of the combination of very mild winters with cold summers; the mean temperature in Hungary for the month of August is 71°6'; while in Dublin it is only 60°8'. In Belgium, and Scotland, the winters are milder than at Milan. The above admirable paper furnishes us with the following

TABLE OF THE ISOTHERMAL BANDS, AND DISTRIBUTION OF HEAT OVER THE GLOBE.

Isothermal bands.	Names of the places.	Position in			Mean temperature of the year.	Distribution of Heat in the different Seasons.				Maximum and Minimum.

* * The temperatures are expressed in degrees of Fahrenheit's thermometer; the longitudes are counted from east to west, from the first meridian of the observatory of Paris. The mean temperature of the seasons has been calculated, so that the months of December, January, and February, form the mean temperature of the winter: The mark * is prefixed to those places, the mean temperatures of which have been determined with the most precision, generally, by a mean of 8000 observations. The isothermal curves having a concave summit in Europe, and two convex summits in Asia and Eastern America, the climate is denoted to which the individual places belong.

Comparing the northern half of the globe with the southern, our author observes, the southern hemisphere differs considerably from the northern; but the degree of this difference has been variously stated; the coldness of the southern hemisphere, has generally been attributed to the circumstance of the sun being a shorter time on the south, than on the north side of the equator. But it probably depends more upon the greater proportion of ocean, which gives to the southern temperate zone a climate more approaching to that of a collection of islands. There is, there-

fore, a less accumulation of heat during the summer, and a less radiation from the land, in proportion to its less extent; and there is consequently a less current of warm air flowing from the equator towards the south pole, which permits the ice to accumulate more around it. Near the equator, and indeed through the whole of the torrid zone, the temperature of the two hemispheres appears to be the same; but the difference begins to be felt in the Atlantic about 22° of latitude; and there is a considerable difference between the mean temperature of Rio Janeiro and Havannah,

though they are equally distant from the equator, that of the former being $74^{\circ} 5'$ and of the latter $76^{\circ} 4'$. The southern climates generally differ from the northern with respect to the distribution of temperature through the different parts of the year. In the southern hemisphere, under the isothermal lines of 45° and 50° , we find summers, which, in our hemisphere, belong to the lines

$35^{\circ} 5'$ and 41° . We are not accurately acquainted with the mean temperature of any place beyond 50° of south latitude; but there is every reason to suppose that it differs considerably from the same degree of north latitude. We extract from his Personal Narrative, the following tabular comparison on this subject, in Fahrenheit's degrees.

Latitude.	Corresponding Months.	Mean temp. of the months.		Latitude.	Corresponding Months.	Mean temp. of the months	
		Southern Hemisphere.	Northern Hemisphere.			Southern Hemisphere.	Northern Hemisphere.
$0-15$	December June	$82^{\circ} 4$	$83^{\circ} 3$		February August	$62^{\circ} 24$	$62^{\circ} 6$
18	October April	81.5	79.3	43	July January	59.36	64.76
$22-26$	January July	72.5	$66^{\circ} 74$	48	June December	44.6	63.86
	September March	69.44	68.9	53	July January	43.16	56.3
34	December June	56.84	59.72				

The observations employed in constructing this table were all made at sea, except those from which the mean temperature at thirty-four degrees was deduced, which were made at the Cape of Good Hope.

The influence of climate on the character and habits of *man* has, naturally, attracted the attention of various modern philosophers and travellers. Humboldt observes, in his Researches, 'Although the manners of a people, the display of their intellectual faculties, the peculiar character stamped on their works, depend upon a great number of causes which are not merely local; it is nevertheless true, that the climate, the nature of the soil, the physiognomy of the plants, the view of beautiful or savage nature, have great influence on the progress of the arts, and on the style which distinguishes their productions. This influence becomes the more perceptible, the farther man is removed from civilisation. What a contrast between the architecture of a tribe that has dwelt in vast and gloomy caverns, and that of the hordes whose bold monuments recall, in the shafts of their columns, the towering trunks of the palm-trees of the desert! An accurate knowledge of the arts can be acquired only from studying the nature of the site where they arose. The only American tribes among whom we find remarkable monuments, are the inhabitants of the mountains. Isolated in the regions of the clouds, on the most elevated plains on the globe, surrounded by volcanoes, the craters of which are encircled by eternal snows, they appear to have admired, in the solitude of their deserts, those objects only which strike the imagination by the greatness of their masses; and their productions bear the stamp of the savage nature of the Cordilleras.

'What a striking spectacle does human genius

present, when we survey the immense disparity that separates the tombs of Tinian and the statues of Easter Island, from the monument of the Mexican temple at Mitla; and compare the shapeless idols of this temple with the masterpieces of the chisel of Praxitelles and Lysippus! But we shall cease to wonder at the rude style, or incorrect expression, of the monuments of the American nations, when we reflect, that, cut off from the rest of mankind, wanderers in a country where man must have long struggled against nature in her most savage and disordered aspect, these tribes, with no resources but in their own energy, could only emerge with tardy progress from their native barbarism.'

A recent contributor to the Classical Journal has, in his essay on the Causes of the diversity in Human Character, investigated the influence of climate on our species with considerable research and ingenuity. Extreme heat clearly darkens the skin, swells the flesh, and produces that general chubbiness of appearance which is so remarkable in the torrid zone. The intermediate degrees of temperature produce proportional effects; and persons born in temperate climates become gradually assimilated to the characters of the warmer ones in case of their migration thither. The original Portuguese and French settlers on the coast of Africa would scarcely recognise the kindred of their descendants, who, retaining a smattering of their original language, are closely assimilated to the native tribes, both in their complexion and in the woolly hair that covers their heads.

'One of the most striking illustrations of the

assimilating powers of climate,' says the writer just alluded to, 'is afforded in the case of the Jews. This tribe is scattered over the whole face of the earth, and, though naturalised in every soil, it is still preserved distinct from the rest of mankind. The Jews, on account of the prejudices of religion, and other causes, never intermarry with any but their own sect. If, therefore, they are assimilated to the people among whom they reside, this cannot be ascribed to a mixture of races. Yet it is found that the English Jew is white, the Portuguese brown, the American olive, and the Egyptian swarthy: so that there are, in fact, as many different species of Jews, as there are countries in which they reside, a diversity which can scarcely be accounted for from any other cause than the influence of climate. And climate,' as this writer further observes, 'has a direct influence in regulating the strength, or weakness of the human constitution; in consequence of which it materially affects the character. The inhabitants of a hot climate are never so robust as those of a more temperate region; extreme heat relaxes the muscular fibre, deranges the natural secretions, and enervates the whole corporeal system. This imbecility of body necessarily has a great effect on the mind; and among such people we have reason to expect timidity and cowardice rather than valor and a capacity to endure hardship. In a climate where moderate cold occasionally prevails, the animal fibre is braced, and all the bodily functions are allowed free play. Here, therefore, we have reason to expect a strong and hardy race, equally qualified to endure the fatigues of the field, and to brave the dangers of war.' In confirmation of this reasoning he cites the imbecile character of the Chinese, the Persians, and the Hindoos, for successive ages.

With indolence we also find the love of luxury and effeminate pleasures prevail in warm climates; together with a remarkable degradation of the female sex. Hence polygamy destroys domestic rule and domestic happiness: woman is the slave altogether of the sexual desires of the master-sex. She is jealously secluded for the sake of her transient charms; and the object of warm passion, at the best, rather than of generous and tender friendship or esteem. Some writers have, indeed, contended, that these climates are favorable to the early stages of science and the arts; and remind us that the 'fertile plains of the south of Asia, are universally respected as the cradle of arts, and of genius.' Soon, however, have they migrated from these regions. 'There has been a continual progress northward from happier climes to those less favored by nature,' observe the same parties; and we conclude, with the writer in the Classical Journal before adverted to, that it is in the temperate regions of the earth therefore, that we are to look for an advanced state of the arts, and there that we are to expect examples of heroic valor, transcendent genius, incorruptible patriotism, and unshaken virtue. And it will not be denied, that historical evidence affords the most direct confirmation of the truth of this doctrine.

CLIMAX, *n. s.* Gr. κλίμαξ. Gradation; ascent; a figure in rhetoric, by which the sentence

rises gradually, as, Cicero says to Catiline, Thou doest nothing, movest nothing, thinkest nothing; but I hear it, I see it, and perfectly understand it.

Choice between one excellency and another is difficult; and yet the conclusion, by a due climax, is evermore the best. *Dryden. Juv. Dedication.*

Rome radiant Richmond every age has graced,
Still rising in a climax, till the last,
Surpassing all, is not to be surpast. *Granville.*

CLIMB, *v. n. & v. a.*

CLIMBER, *n. s.*

CLIMBER (from clamber), *v. n.* } Sax. cli-
} man; Dut.
} klimmen. To ascend up any place; to mount by means of some hold or footing. It implies labor and difficulty, and successive efforts.

And on the Monday, when it drew to night,
He shette his dore withoute candle light,
And shortly up they clomben alle three.

Chaucer. Canterbury Tales.

In scaling the youngest to plucke off his becke,
Beware how ye climber for feading your neck.

Tusser.

Lowliness is young Ambition's ladder,
Whereto the climber upward turns his face.

Shakspeare.

When shall I come to the top of that same hill?—
—You do climb up it now. Look, how we labour.

Id.

It's not enough to break into my garden,

Climbing my walls, in spite of me the owner?
As a thief.

Id.

Into the window climbs, o'er the tiles,

So clomb the first grand thief into God's fold.

Milton.

Thou sun! of this great world both eye and soul,
Acknowledge Him thy greater; sound his praise
In thy eternal course, both when thou climbst,
And when high noon has gained, and when thou fallest.

Id. Paradise Lost.

Here unto Latmos top I climb,

How far below thine orb sublime.

Marvell.

Here I survey the purple vintage grow,

Climb round the poles and rise in graceful row.

Gay.

The path that leads where hung sublime,

And seen afar, youth's trophies bright

In Fancy's rainbow-ray invite

His windy nerves to climb.

Beattie.

Ah? who can tell how hard it is to climb

The steep where Fame's proud temple shines afar,

Ah! who can tell how many a soul sublime

Has felt the influence of malignant star,

And waged with Fortune an eternal war. *Id.*

What is the end of fame? 'Tis but to fill

A certain portion of uncertain paper;

Some liken it to climbing up a hill,

Whose summit, like all hills, is lost in vapour.

Byron.

CLIMBER, a plant that creeps upon other supports; the name of a particular herb.

Ivy, briony, honey-suckles, and other climbers, must be dug up. *Mortimer.*

CLIME, *n. s.* contracted from climate, and therefore properly poetical. Climate; region; tract of earth.

He can spread thy name o'er land and seas,

Whatever clime the sun's bright circle warms.

Milton.

They apply the celestial description of other climes unto their own. *Broune's Vulgar Errors.*

Of beauty sing, her shining progress view,
From *clime* to *clime* the dazzling light pursue.

Granville.

We shall meet

In happier *climes* and on a safer shore. *Addison.*

Health to vigorous bodies, or fruitful seasons in
temperate *climes*, are common and familiar blessings.

Atterbury.

Heart on her lips, and soul within her eyes,

Soft as her *clime* and sunny as her skies. *Byron.*

CLINCH, *v. a. & n. s.* } Sax. *clýniga*, to
CLINCHER, *n. s.* } knock. To hold in

the hand with the fingers bent over it; to bend the point of a nail in the other side, to confirm; to fix, as to clinch an argument, to contract or double the fingers. That part of a cable which is fastened to the ring of the anchor. A cramp; a holdfast; a piece of iron bent down to fasten planks.

Such as they are I hope they will prove, without a
clinch, luciferous; searching after the nature of light.
Boyle.

Pure *clitches* the suburban muse affords,
And Panton waging harmless war with words.

Dryden.

Simois rolls the bodies and the shields
Of heroes, whose dismembered hands yet bear
That dart aloft, and *clinch* the pointed spear. *Id.*
Here one poor word a hundred *clitches* make.

Pope.

The wimbles for the work Calypso found;
With those he pierced 'em, and with *clinchers* bound.
Id.

Their tallest trees are about seven feet high, the
tops whereof I could but just reach with my fist
clinched. *Swift.*

CLINCH, a navigable river of the United States, in the Tennessee government; which rises in the Cumberland mountains, Virginia, and running south-west, crosses the divisional line; thence meandering south-west by west for about 200 miles, unites with the Tennessee, fifteen miles below the Holstein.

CLINCHING, in sea language, a kind of slight caulking used at sea, in anticipation of foul weather, about the posts: it consists in driving a little oakum into their seams, to prevent the water coming in at them.

CLING, *v. n.* } Dan. *klynger*. To hang
CLINGY, *adj.* } upon by twining round; to stick to; to hold fast upon. To adhere, as followers or friends. To dry up; to consume; to waste; to pine away, *Leclungen* $\tau\pi\epsilon\omicron\upsilon\alpha$, a withered tree.

The broil long doubtful stood;
As two spent swimmers that do *cling* together,
And choke their art. *Shakspeare.*

If thou speakest false,
Upon the next tree shalt thou hang alive,
Fill famine *cling* thee. *Id. Macbeth.*

Most popular consul he is grown, methinks:
How the rout *cling* to him! *Ben Jonson's Cataline.*

The fontanel in his neck was described by the *clinging*
of his hair to the plaster. *Wiseman's Surgery.*

When they united and together *cling*,
When undistinguished in one heap they hung.
Blackmore.

See in the circle next Eliza placed,
Two babes of love close *clinging* to her waist.
Pope.

That they may the closer *cling*,
Take your blue ribbon for a string. *Swift.*

CLINICAL, *adj.* } Gr. $\kappa\lambda\iota\nu\omega$, to lie down.
CLINICK. } Those that keep their beds;
those that are sick, past hopes of recovery. A clinical lecture is a discourse upon a disease, made by the bed of the patient. A clinical convert, one that is converted on his death-bed. This word occurs often in the works of Taylor.

CLINK, *v. a., v. n. & n. s.* perhaps softened from clank, or corrupted from click. To strike so as to make a small sharp noise; to utter a small, sharp, interrupted, noise. A sharp, successive noise; a knocking. It seems in Spenser to have some unusual sense. I believe the knocker of a door.

Though creeping clote, behind the wicket's *clink*,
Privily he peeped out through a chink. *Spenser.*

I heard the *clink* and fall of swords.

Five years, a long lease for the *clinking* of pewter.
Shakspeare.
Id.

The severed bars
Submissive *clink* against your brazen portals.
Prior.

Underneath the umbrella's oily shed,
Safe through the wet on *clinking* pattens tread.
Gay's Trivia.

CLINOMETER, an instrument for measuring the dip of mineral strata. It was originally invented by R. Griffith, Esq. professor of Geology to the Dublin Society, and subsequently modified by Mr. Jardine and lord Webb Seymour.

CLINOPODIUM, field-basil, a genus of the gymnospermia order, didynamia class of plants; natural order forty-first, asperifoliae. The involucre consists of many small bristles under the verticillus or whirl of flowers: *CAL.* two lipped: *COR.* upper lip, flat and inversely heart-shaped. There are three species, herbaceous plants, growing from one to two feet high. They are remarkable only for their strong odor, being somewhat between marjorum and basil.

CLINQUANT, *adj.* Fr. Dressed in embroidery, in spangles, false glitter, tinsel finery.

To-day the French
All *clinquant*, all in gold, like heathen gods,
Shoae down the English. *Shakspeare.*

CLINTON (Sir Henry), an eminent English general, and knight of the bath, was the grandson of Francis earl of Lincoln. He became a captain of the guards in 1758, and in July 1766 we find him a lieutenant-general in America. He took an active part during the unfortunate war with that country; but some misunderstanding having taken place betwixt Sir Henry and Lord Cornwallis, the general, after his return to England, published a narrative of his conduct, which was replied to by his lordship, and vindicated by the general. In 1784 he published a farther defence of his conduct; and in 1795 he was appointed governor of Gibraltar, but died soon after.

CLINTON, a county of New York, in the north-east corner, bounded on the east by lake Champlain, on the north by Canada, on the west by Harkemer, and on the south by Washington. It is divided into five townships; viz. Platts-

burg, the capital, Crown-point, Williamborough, Peru, and Champlain. Its form is a parallelogram. It is ninety-six miles long from north to south, and thirty-seven broad from east to west. In 1799 Essex county was erected from the southern part of Clinton county; and, in 1808, Franklin county from the western part. Clinton county is now bounded, north by Canada, east by lake Champlain, or the state of Vermont, south by Essex county, west by Franklin county. Its greatest length north and south is forty miles and a half; greatest width thirty-one miles; and the area is about 1064 square miles, including the waters of the lake, or 680,000 acres.

CLINTON, a large and populous township of New York, in Dutchess county. According to the census of 1810, the inhabitants amounted to 5949, of whom 437 were senatorial electors.

CLIO, from κλειος, glory, in pagan mythology, the first of the muses, daughter of Jupiter and Mnemosyne. She presided over history. She is represented as crowned with laurels, holding in one hand a trumpet, and in the other a book. She sometimes holds a plectrum or quill with a lute. Her name implies honor and reputation, and it was her office faithfully to record the actions of brave and illustrious heroes.

CLIO, in zoology, a genus of insects belonging to the order of vermes mollusca. The body is oblong and fitted for swimming; and it has two membranaceous wings placed opposite to each other; tentacles three and two in the mouth. The species are six, principally distinguished by the shape of their vagina, and all natives of the ocean.

CLIP, *v. a. & n.* } Ang. Sax. *clýppan*; Scot.
CLIPPER, *n. s.* } *clip*. Thus derived, it sig-
CLIPPING, *n. s.* } nifies to embrace, to confine, to fold in the arms. But there is a very different meaning ascribed to it when it is traced to the Goth, *klippa*, and Sax. *clepan* then it signifies to cut, shear, divide.

A merry child he was, so God me save!
—Wel could he leten blod, and *clippe* and shave.

Chaucer. Canterbury Tales.

He kisseth hire, and *clippeth* hire full oft. *Id.*

Your sheers come too late to *clip* the birds' wings,
that already is flown away. *Sidney.*

He that before shunned her, to shun such harms,
Now runs and takes her in his *clipping* arms. *Id.*

Here I *clip*

The anvil of my sword, and do contest
Hotly and nobly with thy love. *Shakspeare.*

O nation that thou couldst remove
That Neptune's arms, who *clippeth* thee about. *Id.*

It is no English treason to cut
French crowns, and to-morrow the king
Himself will be a *clipper*. *Id.*

All my reports go with the modest truth;
Nor more, nor *clipt*, but so. *Id.*

But love had *clipped* his wings and cut him short,
Confined within the purlieus of his court.

Dryden's Fables.

This design of new coinage, is just of the nature of
clipping *Locke.*

We should then have as much feeling upon the
clipping off a hair, as the cutting off a nerve.

Pentley's Sermons.

He spent every day ten hours dosing, *clipping* papers,
or darning his stockings. *Swift.*

By this lock, this sacred lock, I swear,
Which never more shall join its parted hair,
Clipped from the lovely head where late it grew
Pope.

But in man's dwellings he became a thing,
Restless and worn, and stern and wearisome,
Drooped as a wild-born falcon with *clipped* wing
To whom the boundless air alone were home
Eyron.

CLIPEUS, in natural history, a name given to the flat depressed centronix, from their resembling a shield.

CLISSA, a fort of Dalmatia, seated on a craggy mountain, near which there is a narrow valley, between two steep rocks, through which the road lies from Turkey to Dalmatia. It is six miles north of Spalatia. Long. 17° 31' E., lat. 44° 10' N.

CLISTHENES, a celebrated Athenian magistrate, the author of the mode of banishing ambitious citizens by Ostracism.

CLITHEROE, a borough in Lancashire, at the foot of Pendil hill, thirty miles north of Manchester, 217 N. N. W. of London. It has an ancient castle built by the Lacey's, now in ruins. Clitheroe is a borough by prescription, and sends two members to parliament, whose electors are the freeholders and lifeholders. It is governed by two bailiffs, who act together, and are the returning officers. Within these few years, several extensive manufactories of cotton have been established here, which, together with lime-burning, form the chief trade of the town.

CLITORIA, in botany, a genus of the decandria order, and diadelphia class of plants; natural order 320, papilionaceæ. The cor. supine, or reversed with the vexillum or flag petal very large, patent, and almost covering the alæ or wing-petals. There are six species, all herbaceous perennials, or annuals, of the kidney-bean kind, growing naturally in both the Indies. The stalk is climbing, slender, and of the height of a man. The leaves are winged, placed alternately, and consist of two, three, or five pair of lobes, terminated by an odd one. The flowers, which are elegant, stand singly, each on its proper foot-stalk. They are very large, and generally of a deep blue, but sometimes of a white color. From the fruit of this plant is distilled an eye-water. The beans reduced to powder, and taken in broth, to the quantity of two drachms, prove a gentle purge; and Grimmius remarks, in his Labor Ceyl. that the powder of the dried beans, mixed with the milk of the cocoa nut, or with broth, and administered in quantity from one to three drachms, not only mitigates colic pains, but is very useful, and much used in Ceylon, in all disorders of the stomach and bowels. These plants are propagated by seeds; and in this country, must be kept continually in a stove.

CLITORIS, in anatomy, is a part of the external pudenda, situated at the angle which the nymphæ form with each other. Like the penis it has an erection. It is of different sizes in different women; but in general it is small,

and covered with the labia. The preternaturally enlarged clitoris is supposed to constitute an hermaphrodite. When too large, it may be so extirpated as to remove the unnecessary part; but this requires much care, to prevent subjecting the patient to an involuntary discharge of urine. See ANATOMY.

CLITUMNO, a river of Italy, which passes by Spoleto, and joins the Topino, between Spoleto and Perugia.

CLITURNUS, in ancient geography, a river of Umbria, on this side the Apennine. According to Pliny, it was a fountain consisting of several veins, situated between Hispellum and Spolegium; which soon after swelled into a large and navigable river, running from east to west into the Tinea, and both together into the Tiber. Virgil says, it was famous for its milk-white flocks and herds.

CLITUS, in ancient history, the foster brother and intimate friend of Alexander the great. At the passage of the Granicus, Alexander was attacked by Rhæsaëes and Spithridates, two Persian officers of distinction; his helmet was cut through by the battle axe of the latter, and the next stroke would, inevitably, have killed him, had not Clitus, at that instant, rushed to his assistance, and thrust Spithridates through the body with his spear. But Clitus being, some time after, at a feast where some verses in ridicule of the Macedonian officers were introduced by Alexander, angrily expressed his resentment. Being warmed with drinking, he violently retorted on Alexander, and so provoked him that he left the room for his sword. On this the friends of Clitus forced him away, but he soon returned, repeating some insolent verses from Euripides: on which Alexander snatched a spear from one of his guards and ran him through the body. His death however so afflicted Alexander that he attempted his own life, and for some time shut himself up, and would see no one. See ALEXANDER THE GREAT.

CLIVE (Robert), lord Clive, son of Richard Clive esq. of Styche, in Salop, was born in 1725. Towards the close of the war in 1741, he was sent as a writer in the East India service to Madras; but, being fonder of the camp than the counting-house, he soon exchanged his clerk's place for a pair of colors. He first distinguished himself at the siege of Pondicherry in 1748; and acted under major Laurence at the taking of Devi Cotta, at Tanjore, who spoke of his military talents so highly, that he was made commissary-general. When he came over to England in 1753, he was presented, by the court of directors, with a rich sword set with diamonds, as an acknowledgment of his services, at the siege and in the taking of Arcot. Captain Clive returned to India in 1755, as governor of fort St. David, with the rank of lieutenant colonel; when, in conjunction with admiral Watson, he subdued the pirate Angria, and became master of Geria, his capital, with all his accumulated treasure. Surajah Dowla's perfidy soon produced fresh hostilities, which ended in his ruin; he being totally defeated by colonel Clive at Plassey. The conqueror next day entered Muxadabad in triumph; and placed Jassier Ally Cawn, one of the principal generals, on the throne; the dege-

sed soubah being soon after taken, was put to death by Jaffier's son. Mr. Clive was now honored, by the Mogul, with the dignity of an Omrah of the empire; and was rewarded by the new soubah with a jaghire, or grant of lands, producing £27,000 a year. In 1760 he returned to England, where he received the unanimous thanks of the Company, was elected M.P. for Shrewsbury, and raised to an Irish peerage by the title of lord Clive, baron of Plassey. In 1764 fresh and serious disturbances occurring in various parts of Bengal, lord Clive was again appointed to that presidency, and advanced to the rank of major-general in the army. When he arrived in India he exceeded the most sanguine expectation, by restoring tranquillity to the province without striking a blow. He returned home in 1767; and in 1769 was made knight of the bath; but in 1773 a motion was made in the house of commons that 'in the acquisition of his wealth, lord Clive had abused the powers with which he was entrusted.' He defended himself with great ability; enumerating his services for his country, and quoting various letters from the directors of the East India Company, containing the fullest and most ample commendation and approbation of all his proceedings, as well as the congratulation of the direction, in a full court, on his last return home. He was honorably acquitted; the house resolving that lord Clive had rendered great and meritorious services to his country.' Lord Clive was, however, a striking instance of the inefficacy of external honors, and of great wealth, to confer happiness. After his return to England, though in possession of a splendid fortune, and of many advantages, he often discovered great uneasiness of mind and could not endure to be alone. His friends represented this as the result of a depression of spirits occasioned by a nervous fever; but it was attributed by others to causes of a different nature. At last on the 22d of November 1774, he put an end to his own life when not quite fifty years of age; and his remains were interred at Moreton-Say, the parish in which he was born. He left two sons and three daughters: his eldest son, Edward, succeeding him in his title and estate. Lord Clive is said to have given away a great deal of money in acts of benevolence; and he at one time made a present of £70,000 to the invalids in the East India Company's service. Lord Chatham called him a heaven-born general, who, without experience, surpassed all the officers of his time.

CLIVE (Catharine), a celebrated comic actress, the daughter of a Mr. Rafter, was born in the north of Ireland in 1711. She was married, when young, to Mr. Richard Clive, a barrister; but, a separation taking place, she adopted the comic line of a theatrical profession, and was ever sure to fascinate her audience. Her native wit and playful humor are exemplified by the following anecdote:—She performed at Drury-lane under the management of Garrick, and one night, while playing the lady in *Lethe*, Mrs. Clive, turning her head towards the stage-box, chanced to encounter the eye of Charles Townshend. That celebrated wit pointed instantly to an old belle on his left, a caricature of the ridiculous dame she was portraying. The actress paused for a moment, and burst into a long, very, and loud

galleries caught the jest, and joined boisterously in the mirth. Garrick, chagrined by the indecorum of the incident, hastened to the Green-room, to meet Mrs. Clive, 'Madam,' said he, 'your smiles are always despotie; it was those of Mrs. Clive which called down that burst of merriment just now; to-morrow night I hope it will be excited by those of the character she may intend to personate.' She comprehended his meaning, and sportively shutting her eyes, she tapped them with her fan, exclaiming—'I whip the truants that brought me into the scrape; they never again shall so betray their mistress.' Mrs. Clive at length retired to pass the latter part of her life at Little Strawberry Hill, where many persons of rank and eminence courted her society. Her death occurred in 1785.

CLIVER, *n. s.* Teut. & Belg. *stein, claver*; stone clover. The plant melilot, more properly written cleaver. It grows wild, the seeds sticking to the clothes of such as pass by them. It is sometimes used in medicine.

CLOACÆ, in antiquity, the common sewers of Rome, to carry off the soil of the city into the Tiber; justly reckoned among the greatest works of the Romans. The first, called Cloaca Maxima, was built by Tarquin I. of huge blocks of stone joined together without any cement, in the manner of the edifices of those early times; consisting of three rows of arches one above another, which at length conjoin and unite together; measuring, in the clear, eighteen palms in height, and as many in width. Under these arches they rowed in boats, which gave occasion to the remark of Pliny that the city was suspended in air, and

that they sailed beneath the houses. Under these arches also were ways through which carts loaded with hay could pass with ease. It began in the Forum Romanum; measured 300 paces in length; and emptied between the temple of Vesta and the Pons Senatorius. There were as many principal sewers as there were hills. Pliny concludes their firmness and strength from their standing for so many ages the shocks of earthquakes, the fall of houses, and the vast loads and weights moved over them.

CLOACINA, the goddess of common sewers.

CLOAK, *n. s.* & *v. a.* } Barb. Lat. *cloca*.

CLOAK-BAG, *n. s.* } Sax. *lach*. The primary sense is, a garment; its secondary, a covering that conceals. A cloak-bag is a bag which receives or conceals wearing apparel.

Not using your liberty for a *cloak* of maliciousness,
Peter.

Most heavenly fair, in deed and view,
She by creation was, till she did fall;
Thenceforth she sought for helps to *cloak* her crimes
withal.
Spenser.

Why dost thou converse with that trunk of humours,
that stuffed *cloakbag* of guts?
Shakspeare.

I have already fit
(Tis in my *cloakbag*) doublet, hat, hose, all
That answer to them.
Id.

You may hear it
Under a *cloke* that is of any length.
Id.

We will not live his thin bestained *cloak* with our
sure honours.
Id.

Their *clokes* were cloth of silver, mixed with gold.
Dryden.

C L O C K S.

CLOCK, *n. s.* } Goth. *kloeka*; and Sax.
CLOCK-MAKER, *n. s.* } *clecuan*, to strike, to
CLOCK-WORK, *n. s.* } sound. The instrument
which, by a series of mechanical movements,
tells the hour by a stroke upon a bell.

Wel sikener was his erowing in his loge,
Than is a *clock*, or any abbey or loge.

Chaucer. Cant. Tales.

If a man be in sickness or pain, the time will seem
longer without a *clock* or hour-glass than with it.

Bacon.

The picture of Jerome usually described at his study,
is with a *clock* hanging by. *Broune's Vulgar Errors.*

I told the *clocks* and watched the wasting light.
Dryden.

Resolve by sines and tangents straight,
If bread or butter wanted weight,
And wisely tell what hour of the day
The *clock* does strike by Algebra. *Hudibras.*

This inequality has been diligently observed by several
of our ingenious *clockmakers*, and equations been
made and used by them. *Derham.*

So if unprejudiced you sean,
The goings of this *clock-work* man;
You find a hundred movements made
By fine devices in his head;
But 'tis the stomach's solid stroke,
That tells this being what's o'clock. *Prior.*

Within this hollow was Vulcan's shop, full of fire
and *clockwork*. *Addison.*

You look like a puppet moved by *clockwork*.
Arbutnot.

Fate seemed to wind him up for fourscore years;
Yet freshly ran he on ten winters more,
Till like a *clock* worn out with eating time,
The wheels of weary life at last stood still.

Lee's Oedipus.

Clock, in horology, is a machine so regulated,
by the uniform action of a pendulum, as to measure
time by a series of vibrations in the oscillating
body. Under this head, therefore, we propose to treat
of the structure and internal mechanism of those
machines which owe their property of keeping time to
the continued operation of a pendulum, leaving the
portable chronometer, or **WATCH**, to its appropriate
place in our alphabetical arrangement.

The earliest complete *clock*, of which there is
any certain record, was contrived in the thirteenth
century. It was constructed by a Saracen mechanic,
who received about £2000 for his ingenuity. This
clock is stated to have kept time very accurately,
and it was afterwards presented to the emperor
Frederic II. by the Sultan of Egypt, under whose
direction it was made. Some time after this period,
a *clock* was placed in a small building, erected for
the purpose, in the

city of Westminster, the expense of which was defrayed by a fine imposed on one of the judges for malversation in his office. In the fourteenth century an artist, named James Dondi, a Venetian, constructed a clock for the city of Padua, which was long considered as the wonder of that period. Besides indicating the hours, it represented the motion of the sun, moon, and planets, and also pointed out the different festivals of the year. On this account Dondi obtained the surname of *Horologio*, which became that of his posterity. About the same period William Zelandier constructed, for the same city, a clock still more complex, which was repaired in the sixteenth century by Janellus Turrianus, the mechanist of Charles V.

About the year 1560 Tycho Brahe was in possession of four clocks, which indicated hours, minutes, and seconds, the largest of which had only three wheels, one of which was three feet in diameter, and had 1200 teeth in it, a proof that clock-work was then in a very imperfect state. Tycho, however, observed, that there was an irregularity in the going of his clocks, which depended upon the changes in the atmosphere; but he does not appear to have known how such effect was produced. In the year 1577 Moestlin had a clock so constructed as to make just 2528 beats in an hour, 146 of which were counted during the sun's passage over a meridian or azimuth line, and determined his diameter to be $34^{\circ} 13'$, so that the science of astronomy began thus early to be promoted by the assistance of clock-work; and, as clocks first promoted the study of astronomy, it will be seen by and bye, that astronomy, in its turn, gave rise to some of the most essential improvements in clock-work; and that, as the arts and sciences became more and more cultivated, improvements in clock-work kept pace with them, and employed the talents of the most ingenious men of each succeeding age.

As the construction of every modern horological machine must depend, mainly, on a judicious combination of wheel-work, it may be desirable to examine, first, the principle of a common wheel and pinion, and then to show its application to the movement of a clock.

In the wheel and axis A, B, fig. 1. plate I. of *HOROLOGRY*, two cords of similar length are made to support weights, attached to their lower extremity; the weights being placed in equipoise, although the one is twice as heavy as the other. This apparently paradoxical effect is produced, by giving a mechanical advantage to the cord B, which is twice as far from the centre, or fulcrum, as the one that supports the larger weight: the velocity of the two weights are effected also in an equal ratio. So that if the wheel be made to revolve upon its axis, the weight marked 1 will descend two feet, while the opposite side will only be raised one foot. Here then the gain in power is compensated for by a loss of time, and vice versa; and upon this circumstance depends the advantageous use of a wheel and pinion.

In fig. 2, the pinion D. is supported by a separate axis, round which it is made to revolve; and the wheel B B, being three times as large as

the pinion, the latter will make three revolutions to one of the former, or about one revolution for the portion of a circle shown in the diagram. If we consider the weight C as the maintaining power, it will be evident, that, for every revolution made by its axis, there will be three revolutions of the next wheel in succession.

If we combine a series of wheels and pinions, a still greater increase in speed will result. This is shown at fig. 3; and it will be seen that there are four revolutions of the pinion *c* for one of the wheel that drives it; and as the wheel *d* is attached to the same axis, the pinion *e* will make sixteen revolutions to one of the prime mover.

A reference to this simple mode of increasing velocity in wheel-work, will readily explain why a clock, which makes but twelve revolutions at the barrel, is enabled to beat half and quarter seconds, and even to go as many days as there are turns at the prime mover.

Having determined upon the kind of clock to be made, the first thing to be done, and that in which the clock-maker is generally deficient, is, to calculate the movement, or proper number of teeth in the wheels, and of leaves in the pinions of the going part of the mechanism. Dr. Derham, in his *Artificial Clock-maker*, has treated this subject at considerable length; and has laid down rules which have tended more to puzzle than to assist the workman in the choice of his numbers. He proposes to take at random, a certain number of vibrations per hour for a pendulum of an assumed length, to represent his train, and then to find the factors or numbers, which, used as multipliers, shall give the regular product, or nearly so; after which each factor is represented by a ratio of two optional numbers, to constitute a wheel and its pinion. We will not here follow the Doctor through his processes, but merely observe, that, by calculating his whole movement at one operation from an assumed number of vibrations, he has introduced a variety of such trains into portable clocks and watches, as make a vibration of the short pendulum, and an oscillation of the balance, no exact fraction of a second; in short, he has begun at the wrong end of the business; has first fixed on the length of his pendulum, in inches, without considering exactly the number of vibrations it would make, and then calculated a train that would so nearly suit it, that the adjustment for time, by the bob, would compensate the defect of the numbers; the consequence has been, that the exact value of a vibration in a portable clock, and of an oscillation in an ordinary watch, has hitherto been disregarded in the construction. On the contrary, we recommend to the clock-maker, first to fix upon his number of vibrations per second, and then to calculate the true length of his pendulum, and exact value of his train, agreeably to the number of vibrations per second that he previously determined. The most simple way of calculating the numbers proper for the movement of any clock, intended to show seconds, is, by dividing it into three portions, and then by calculating the wheels and pinions for each separate portion, by a separate calculation, beginning at the bottom of the train; thus, we first fix upon the pinion of the hour arbor to be, suppose eight.

Fig. 3.

Fig. 1.

Fig. 4.

Fig. 2.

which is a good, practical number; and as our piece is to go eight days, we will make the fusee to revolve in twelve hours, which construction will require the great wheel on its arbor to be $8 + 12$, or 96, because the pinion of 8 revolves with the minute-hand on its projecting pivot, in one hour; hence if we divide 192, the number of hours in eight days, by 12, the time of one revolution of the great wheel, the quotient 16 will be the number of effective spiral grooves necessary to be cut on the circumference of the fusee, in order that the piece may go just eight days. This portion of the movement is not, however, called a part of the train, but only determines, as has been said, the time that the clock shall continue to go, after each winding up of the maintaining power; and it is easy to conceive, that, if a fusee or a barrel, with twenty-four turns of the catgut or chain, were placed on the hour arbor, the clock would go a natural day without the large wheel; and, also, that if an intermediate wheel and pinion were placed on the arbor between the hour arbor and the great wheel, the time of going might be prolonged to ten, twelve, or even twenty times eight days, but then the maintaining power must be proportionably increased, which circumstance renders such a construction by no means desirable in a regulator, particularly as the auxiliary spring, now in use, will keep the piece in motion during the act of winding up.

The remaining portion of the movement is properly called the *train*, including those wheels and pinions only which are used for counting the vibrations made in an hour; the train is most easily ascertained by two calculations, one for the two wheels and two pinions which multiply the minutes into seconds, and the other for that wheel and pinion, or those wheels and pinions, which subdivide the seconds into vibrations; the former of these two portions of the train, like the first portion of the movement, or portion for the period of continuance, is the same for all clocks, let the time of vibration be what it may: a circumstance not usually considered. The ratios of velocity to be gained by the pinion on the arbor of the seconds' hand, compared with the wheel on the arbor of the minutes' hand, is required to be 60 : 1; which effect might be produced by one wheel of 300 teeth and a pinion of five leaves, as is done in some of the ornamental French pieces; but the size of the wheel is cumbersome, therefore a pair of wheels, with a pair of pinions, one constituting a ratio or vulgar fraction equal in value to $\frac{8}{60}$, and the other equal to $\frac{1}{60}$, making $8 \times 7\frac{1}{2} = 60$, or any other two numbers making a similar product will produce the same effect with fewer teeth; for, if the pinions be each 8, the wheels, in this case, will be respectively 64 and 60, the compound ratio, $\frac{8}{64} \times \frac{8}{60}$, being equal to the simple $\frac{8}{60}$; and by the same process, if pinions of 10 had been chosen, the wheels would have been $8 \times 10 = 80$, and $10 \times 7\frac{1}{2} = 75$, which numbers would, indeed, have less friction than the preceding ones by reason of their teeth acting at less depth, the diameters of the wheels remaining the same, and would, moreover, be capable of acting more behind than before the line joining the centres of the wheel and pinion; in like

manner pinions of 6 would require wheels of 48 and 45, and pinions of 12, wheels of 96 and 90.

The last portion of the movement, or second portion of the train, for a half-seconds' pendulum, will require only one wheel of sixty teeth on the seconds' arbor, properly shaped for the escapement; for, as one tooth in the dead-beat and common anchor escapements escapes completely at two vibrations of the pendulum, sixty teeth will escape, that is a whole revolution of the seconds' hand will be made, in 120 vibrations; if, however, the pendulum had been required to vibrate seconds, the wheel in question, usually called the swing wheel in opposition to the crown wheel which requires another escapement, would have demanded only thirty teeth for that purpose: and, if three vibrations had been fixed upon, the number to correspond must have been ninety, otherwise there must have been a wheel and pinion of the value of three, like $\frac{3}{3}$ or $\frac{10}{10}$, an addition to the usual swing wheel of thirty, or, which is the same thing, a wheel and pinion of the value of six, like $\frac{6}{6}$ or $\frac{10}{10}$, must have been introduced between the seconds' arbor and a pallet, or a swing wheel of 15. Thus all the variety in the calculation of trains, where seconds are indicated, is confined as we have intimated to the last portion of the movement, and the calculation itself so simple, that the mere altering of the numbers of the pallet-wheel will convert a clock with a seconds' pendulum into one with half-seconds, and vice versa.

The calculation of numbers suitable for an eight-days' clock, with a half-seconds' pendulum, being thus readily obtained by three simple operations, which may be had by mere inspection of the three tables which we shall presently subjoin, the whole may be represented, and its value estimated again, by a compound fraction,

thus: viz. $\frac{8}{96}$ of $\frac{8}{64} \times \frac{8}{60}$ of $\frac{1}{60 \times 2}$ of twelve hours, or, which is the same thing in effect, thus $\frac{8}{96} \times \frac{8}{64} \times \frac{8}{60} \times \frac{1}{60 \times 2} = \frac{512}{44236800} = \frac{1}{64800}$ of twelve hours, or 86400 vibrations in twelve hours, which is the time of a revolution of the fusee, and great wheel, 96, on its arbor, and therefore $\frac{86400}{12}$, or 7200 vibrations, each of half a second in duration, in one hour, constitute the value of this train.

This mode of notation gives the value better than any other, perhaps, that has been adopted; but the position of the wheels and pinions will be better understood from the ordinary mechanical method of writing them down thus:—

Great wheel 96
 Pin 8—64 hour wheel
 Pin 8—60 second wheel
 Pin 8—60 swing wheel
 2 pallets.

Indeed it is difficult to write down the movement by any one notation that shall express, at the same time, both the value and position of the wheel-work, on which account we recommend the workman to write down his numbers by both

forms, taking care, in the method by compound ratios, to put all the drivers under the line of division, and all the driven ones above; so that, when an ascending movement is represented, the wheels may be the denominators, and, when a descending one, the pinions.

The arrangements for calculating a train, and, as such, of forming a clock movement having been examined, it may now be advisable to revert to the mode of regulating the wheel-work by what is called an *escapement*. The term is derived from the French *eschappement*, and it is employed to illustrate the action of the pallets in connexion with the last wheel in the train, the teeth of which may be said to escape at each oscillation of the pendulum.

The earliest mode of forming a pair of pallets, or verge, being exactly similar to that employed in the regulation of a common watch, will be fully examined in another department of our work, and it may be enough to say, that its application to the best constructed horological machines has been long since abandoned.

The swing or scape-wheel, represented at fig. 4. plate I. HOROLOGY, is furnished with a pair of pallets, C, D. The wheel passing in the direction of the arrow resting on the pallet C, and as the pallet's arbor, B, is connected with the pendulum by a rod or crutch, the pendulum must oscillate in the same direction. Passing down the inclined plane the tooth is now found to escape, still turning in the same direction. The wheel then rests on the pallet D, and, being aided in its operation by the tendency of gravity to bring back the pendulum, soon passes to the pallet on the opposite side, and the process is repeated as long as the train continues its impulse.

Having thus briefly examined the action of a common anchor escapement; which, from its great simplicity, has been placed first in the order of arrangement, it may now be advisable to direct the reader's attention to the pallets without recoil, invented by the late Mr. George Graham. In this escapement the seconds' hand stands still after each drop of the pallets, and hence the term *dead-beat*, whereas the hand of a clock regulated by the recoiling escapement is always in motion, oscillating backwards and forwards.

Mr. Vulliamy's improved mode of constructing an escapement without recoil, is represented fig. 5, in which the pallets AA are allowed to expand or contract, by the motion of a double screw, B; and this escapement differs from all the others in the accuracy with which the acting parts are formed, nearly the whole of the pallets with their frame being executed in the lathe.

To form the pallets a ring of steel is, in the first instance, prepared of the required size, and the arms, L, M, turned with a circular groove to receive it. The ring may then be cut in short lengths, and inclined planes formed at the proper angle. The two arms of the pallet frame are held together by the collet and screws Y, Y, and the regulation is performed by the larger end of the screw B, being furnished with a coarser thread than its other extremity, so that the dispo-

portion between them is capable of producing the most delicate adjustment.

The great advantages in this mode of construction are. 1. That the rests of the pallets are correct portions of circles; the centre of which circles is the centre of motion of the axis of the verge, and the pallets move in the same circles, and, consequently, there will not be any recoil in the escapement. 2. That the pallets must be of equal thickness, and consequently the drop the same on both. 3. That the pallets may be made perfectly hard, if properly treated, without risk of altering their shape: and should a pallet be spoiled by an accident in hardening, or a flaw or imperfection of any kind be discovered, another exactly similar is easily made to replace it out of the original ring. When the pallets are made out of the same piece of steel as the arms of the frame, it is difficult to preserve their shape correctly in hardening, and to retain the acting part of the pallet perfectly hard. To obviate this difficulty, the pallet has sometimes been made a separate piece, with a short arm, by which it is fixed with two screws to the arm of the frame; but this is only to exchange one evil for another, as, independent of other disadvantages, which it is unnecessary to enumerate, it is very uncertain, with the pallets fixed in this manner, whether or not the rests of the pallets are concentric with the centre of the axis of the verge. The slightest deviation from its original direction in the arm of the pallet, by hardening or any other cause, has the effect of removing the centre of the circle, forming the rest of the pallets, from the centre of the axis of the verge to some other place, the consequence of which is to render the escapement a recoil escapement. 4. That the mode here recommended of constructing the pallets, offers a great facility for making the inclined planes of the pallets equal to one another, or of altering them, as may be required; and consequently the angle which the pendulum is led by one pallet, will be equal to the angle led by the other.

To a person unacquainted with the mechanism of a clock, the pendulum appears but as an appendage to a very complicated machine; whereas, the fact is, that the series of wheels and maintaining power we have now been describing, are, in reality, but appendages to the pendulum, every part of the machine being constructed in subservience to its motion. From this then it will be seen, that it is the pendulum which is the efficient measurer of time, whilst the office of the wheels is to record the divisions marked by its oscillations; so far, indeed, are the wheels from contributing towards the regularity of the pendulum, that they are mostly found to disturb it. The office then of the wheels is to prevent the pendulum coming to a state of rest, which it effects by repeated impulses, at stated periods.

The honor of first applying a pendulous body to regulate the time in horological machines, has been claimed by mechanics in almost every part of Europe: indeed the Arabians, as far back as the time of caliph Haroun Alraschid, state their claims to the invention, although it is

more than probable, that, if the use of the pendulum were known in the east prior to the seventeenth century, it was employed without the accompanying train of wheels which constitute a modern clock.

If the resistance arising from the friction at the moving parts, and from the motion communicated to the air, were always the same, and the clock were urged by a weight, the action of the swing-wheel on the pallets would be always the same at a given place, in consequence of which, the figure of all the parts being supposed invariable, the arc of vibration would be constantly of the same magnitude; namely, such as, that the motion lost by the resistances opposed to the pendulum should be accurately equal to the motion communicated by the pallets, and the times would be equal; that is to say, the clock would be perfect, and would measure time accurately. But these conditions are not easily obtained. It is not found, however, that the variation in the resistance of the air, arising from its change of density, occasions any sensible irregularity in clocks. The most considerable irregularities in the movement arise from the tenacity of the oil applied to the moving parts. For the oil is less fluid in cold than in hot weather; and when it is less fluid, a greater quantity of the maintaining power must be lost in overcoming its rigidity; whence it must happen, that the teeth of the crown-wheel will, in that case, act forcibly on the pallets, and the vibration will be less. If the pendulum be suspended on an axis, this cause, together with the constant wear, is very injurious to the performance of the machine, but this defect is remedied by suspending it by a straight flexible spring, as is shown in fig. 6 to 14 of plate I. HOROLOGY.

The rod of the above pendulum should be made of straight grained yellow deal, which may be procured from the lath-maker's, it should be split down both ways; neither the sort which is white and spongy, nor that which is of a strong grain, and full of turpentine. The rod is a cylinder of about five-eighths of an inch diameter, and forty-two inches long; it should be dried and gilt, and if varnished it would be less subject to changes from moist weather. The rod being first roughed out, a brass ferrule (*a*, fig. 6 above), must be driven on its lower end, previously turned to receive it, the rod is then to be put into the lathe, the ferrule turned true, and a few other places in the rod may likewise be made round; the whole is afterwards to be planed straight, round, and smooth; a hole is then to be drilled at the bottom of the rod, to receive the wire *b* along the axis. This wire should be steel, and the part which goes into the rod a little taper, and rather larger than the hole in the end of the rod, the rest of the wire cylindrical, and the end conical; a screw must be cut upon the cylindrical part with stocks; the wire must be forced into the hole at the bottom of the rod, and then cross-pinned through both ferrule and rod, as at *P*. The top of the rod, fig. 9, is slit along the grain with a fine spring saw, to receive the spring at *X*, by which the pendulum is suspended; the two parts are

drawn together by a screw, and made to pinch the spring; this screw passes through the quarter part of a brass ferrule, and is tapped into the opposite quarter part; the head of the screw, with the first quarter, appears at *c*, fig. 9. The spring is a piece of strong watch-spring, which has not been coiled up; the upper part has two cylindrical buttons rivetted to it, opposite to each other, one of these appears at *Z*; these bear the weight of the pendulum during the time of adjusting its suspension, before the screws are drawn tight. The ball of the pendulum is made of lead, and consists of two parts screwed together upon the rod, so as to pinch it. Fig. 7 is the ball as it appears edgewise, and shows the section down the axis of the rod where the two parts join. The shape of the ball, when the two parts are screwed together, is the middle frustrum of a globe, as is seen by the figure. These two parts should be moulded from a neat turned pattern of wood, where the hole should be left to receive the rod; they may be cast so near their true form, as to give but little trouble in turning down in the lathe and finishing; if the pattern be made true, the axis of the rod will pass through the centre of gravity of both. Fig. 6 is the pendulum seen flatwise; two pieces of brass are soldered to the back part of the bow, and tapped to receive the screws which fasten the two parts together; one of these pieces appears at *y*, fig. 12. The place of the ball upon the rod being found, it is then to be screwed fast to the rod, and not to be removed to regulate the clock. On the screw part of the wire, at the bottom of the pendulum-rod, is a cylinder of brass in two parts, the screw passing through the centre of both parts. The upper part, *d*, *d*, fig. 6, consists of a milled torus, and a plain cylindrical part, both in one piece; the cylinder has numerical figures engraven on it, in the order they are represented in the plate, the lower part consists of a milled torus only, as at *e*, *e*. When the upper part is screwed to its proper place, it must be held fast, and the lower part screwed against it, so as to pinch the screw-wire, and secure it against any accidental turning. Whenever there is occasion to move the upper part (in order to regulate) the under part must first be detached till the adjustment be made, and then screwed close again, as before. This part may be called the regulator, and will perform that office with a much greater degree of correctness than where the whole ball of the pendulum is moved.

Having thus described the pendulum-rod with its ball, we may now describe the proper method of suspending it, which is by a projecting cock made of brass, and is composed of three distinct pieces, fixed together with rivets and screws. It is difficult to give the exact form without giving many views of it; but the general principle may be easily explained. Strength and steadiness are particularly sought in its formation, and the side view, fig. 9, will make it appear how these are attained in the vertical line, by the part marked *a*, *a*, above the line of suspension, and that marked *c*, *c*, below the line, as these serve as strong brackets each

way; but the part which serves as its principal support in the horizontal line does not appear in the side view, but may be seen in fig. 11. The form of the part from b to b_1 is the same as that seen in the side view from the dotted line e to c . The screw marked at Z , fig. 9, appears sideways in the plan; this screw goes through the two parts, which project forward to hang the pendulum upon. The right angled part d, d_1, b, b_1 , fig. 11, is fixed to the flat brass plate by three rivets, as large as their thickness will admit, one at the angle near the lower b , and one at each extremity of the piece; the parts are put together by rivetting, that, when separate, they may be hammer-hardened. This cock is firmly fixed to a strong piece of wainscot, which is placed against the back of the clock-case, and the whole firmly attached to the wall. The mode of suspension should be such, that none of the lateral motion of the pendulum, as it vibrates, can be communicated to the other parts of the apparatus, nor should the whole be liable to be disturbed by foreign causes. The two planes of the cock at Z , which are to receive the string between them, should be filed flat when the plate T is taken off, and thus the spring may be pinched firm between them; so also should the cheeks of the slit at the upper end of the rod, so that the spring should not have the least play at either of its terminations; otherwise, its force will be very unequal. In placing the cock, care should be taken that the place where the spring bends, fig. 9, should be adjusted to the level of the verge or arbor of the pallets at $A H$.

When the pendulum is to be suspended upon the cock, take out the screw in fig. 9, and release the opposite one at 2, and hang the pendulum-spring between the two planes at Z , fig. 9, putting the cylindrical buttons, which are rivetted at the top of the spring, into the hollow made to receive them at Z , then return the screw into its place, but do not tighten it; then tighten the screw c , at the top of the pendulum-rod, and afterwards the two screws, $H Q$, which will secure it in its place; and from its having hung freely, before these screws were tightened, the several parts will have been drawn into the true perpendicular line; the clock is afterwards put to it. We may now explain the contrivance by which the pendulum receives its impulses from the wheel-work. A , fig. 12, is the verge or arbor, on which the pallets are fixed; $1 1$, is a round piece of brass rivetted to the collet; $k k k$ is the stem of the crutch, seen edgewise, and in fig. 13, it appears flatways. In the centre of the upper part is a round hole, A , made to fit the verge; and at $1, 2$, are two circular slits. In fig. 12, at $2, 2$, is another round piece of brass, fitted rather loose on the verge; the screw at A , and another on the opposite side, go through the fixed plate marked $1 1$, and also through the curved slits on fig. 13, marked $1, 2$, and are tapped into the plate, marked $2 2$, fig. 12, so that the crutch has a considerable motion round the centre of the verge, and may be fixed in any position by these screws, one of which only can appear in this view, and is opposite to A , fig. 12. At the other end of the stem of the crutch, fig. 13, is a hole to receive the screw-

shank of the steel piece seen edgewise, fig. 8, and, when screwed up, appears at K, L . The sides of this piece must be filed flat, and polished: or at least a fine grain given to it; its thickness should be about $\frac{1}{4}$ of an inch; the end of the flat part is seen at fig. 14. The shoulder marked $w w$, at fig. 8, should be turned flat, and when the screwed shank is put through the hole B of the crutch, in order to fix it, a collet of brass should be interposed between the nut and the face of the crutch; this collet or brass plate should be turned hollow towards the crutch, and somewhat round towards the nut, which will make the fitting more effectual. The flat faces of the steel plate must be set parallel to the line $A B$, fig. 13. An oblong hole is pierced through the wooden rod, fig. 14, in the direction of the axis of the rod; two fine steel screws $s s$, are tapped through the sides of this hole. These screws pinch the flat part of the steel piece between them; the ends of the screws which bear against the plate are somewhat rounded off; the ends of these screws, and the flat part they bear against, must be made as hard as possible. The holes for the screws must be made at right angles to the flat sides of the faces of the steel piece, and must pass through the axis of the rod. These screws are $\frac{1}{8}$ of an inch in diameter, and have eighty threads in an inch. They must be forced in so as to cut their own threads in the wood, after which they must never be turned quite out. After having properly suspended the pendulum, and come to set up the clock, draw back the screws s, s , fig. 14, so as to leave room for the flat of the steel part, T , to enter clearly between them. To put the clock in beat, release the screws at A , fig. 12, and its opposite screw, (which is hidden in this view,) so as just to let the verge move stiff in the hole of the crutch. The frame containing the wheel-work must then be set into its place, carefully directing the flat of the crutch between the screws, which pass through the sides of the rod. After having screwed down the frame of the work to the rising board as usual, the crutch must be held fast while the pallets and verge are turned so as to bring the clock into beat. The screw at A , fig. 12, and its opposite must then be tightened, so as to set the pallets and verge fast to the crutch. The back frame must be cut so as to get at the heads of these screws with a key from the front of the clock. These screws have square heads, not slits, and are turned with a key, to prevent the thrusting forwards which is necessary when a turn-screw is used. The clock may be adjusted into beat with the greatest nicety, by releasing one of the screws, s, s , fig. 14, and screwing up the other; taking care not to overturn these screws so as to strip the threads in the wood. The rule to be observed is this: the artist must always hear the flat, T , strike against the screws, and if it be but heard, they cannot be too close; these parts should be oiled. O, P , fig. 10, is a piece of steel wire, which passes through the axis of the rod in order to catch it, by means of two slips of wood properly cut and fastened to the rising board, so that this wire just keeps clear of it, in the vibrations of the pendulum. The ingenious clock-maker will easily perceive, that if the above work be carefully ex-

ecuted, according to the directions given, the impulses will be given in the axis of the pendulum-rod, and thence conveyed to the centre of gravity of the ball: two circumstances absolutely necessary to produce a steady and regular motion of the pendulum.

Dr. Franklin contrived a clock, represented at fig. 15, to show the hours, minutes, and seconds, with only three wheels and two pinions in the whole movement. The dial-plate, it will be seen, has the hours engraved upon it in spiral spaces, along two diameters of a circle, containing four times sixty minutes. The index A goes round in four hours, and counts the minutes from any hour which it has passed to the next following hour. The time, therefore, in the position of the index shown in the figure, is either thirty minutes past XII, IV, or VIII; and so in every other quarter of the circle it points to the number of minutes after the hours which the index last left in its motion. The small hand B, in the arch at top, goes round once in a minute, and shows the seconds. The wheel-work of this clock may be seen at fig. 16. A is the first or great wheel, containing 160 teeth, and going round in four hours, with the index-hand connected by a hole through its axis. This wheel turns a pinion of ten leaves, which, therefore, goes round in a quarter of an hour. On the axis of this pinion is the wheel C, of 120 teeth, which goes round in the same time, and turns a pinion D of eight leaves round in a minute, with the seconds' hand B fixed on its axis, and also the common wheel E of thirty teeth, for moving a pendulum, by pallets, that vibrates seconds, as in a common clock.

This clock is wound up by a cord going over a pulley on the axis of the great wheel, like a common thirty-hours' clock. Many of these admirably simple machines have been constructed, which measure time exceedingly well. It is subject, however, to the inconvenience of requiring frequent winding by drawing up the weight, and likewise to some uncertainty as to the particular hour shown by the index A. Mr. Ferguson has proposed to remedy these inconveniences by the following construction: in the dial-plate of the clock, fig. 17, there is an opening, *a, b, c, d*, below the centre, through which appears part of a flat plate: on this the twelve hours, with their divisions into quarters, are engraved. This plate turns round in twelve hours: and the index A points out the true hour, &c. B is the minutes'-hand, which goes round the large circle of sixty minutes whilst the plate *a, b, c, d*, shifts its place one hour under the fixed index A. There is another opening, *e, f, g, h*, through which the seconds are seen on a flat moveable ring, at the extremity of a fleur-de-lis, engraved on the dial-plate. The great wheel of this clock, containing 120 teeth, and turning round in twelve hours. The axis of this wheel bears the plate of hours, which may be moved by a pin passing through the small holes drilled in the plate, without affecting the wheel-work. The great wheel A, fig. 18, turns a pinion, B, of ten leaves, round in an hour, and carries the minutes'-hand B on its axis, round the dial-plate in the same time. On this axis is a wheel, C, of 120 teeth, turning round a pinion, D, of six leaves,

in three minutes; on the axis of which there is a wheel, E, of ninety teeth, that keeps a pendulum in motion, vibrating seconds by pallets, as in a common clock, when the pendulum-wheel has only thirty teeth, and goes round in a minute. In order to show the seconds by this clock, a thin plate must be divided into three times sixty, or 180 equal parts, and numbered, 10, 20, 30, 40, 50, 60, three times successively, and fixed on the same axis with the wheel of ninety teeth, so as to turn round near the back of the dial-plate; and these divisions will show the seconds through the opening, *e, f, g, h*, in the dial-plate. This clock will go a week without winding, and always show the precise hour; but this clock, as Mr. Ferguson candidly acknowledges, has two disadvantages, from which Dr. Franklin's clock is free. When the minutes'-hand, B, is adjusted, the hour-plate must also be set right by means of a pin; and the smallness of the teeth in the swing wheel will cause the pendulum-ball to describe but small arcs in its vibrations: and, therefore, the momentum of the ball will be less, and the times of the vibrations will be more affected by any unequal impulse of the pendulum-wheel on the pallets. Besides, the weight of the flat ring on which the seconds are engraved will load the pivots of the axis of the pendulum-wheel with a great deal of friction, which ought, by all possible means, to be avoided. This inconvenience might, however, very easily be remedied by omitting the second plate.

The term clock, which is usually applied indiscriminately to all horological machines, belongs in reality to those instruments alone which indicate the hour by means of a bell, and, although we have already shown that striking clocks are of considerable antiquity, the striking portion certainly belongs to a period long subsequent to the first invention of those highly useful machines.

It may now be advisable to examine what is termed the *striking part*, and for its better illustration we have separated that part of the train from the rest of the movement. In the annexed diagram *h* represents the barrel-wheel, furnished with a ratchet and click to prevent the return of the barrel. The wheel *h* turns a pinion of eight teeth, on the same arbor with which pinion is the wheel *i*, turning a similar pinion on the arbor of the wheel *k*. The wheel *k* turns another pinion of eight on the same arbor with the wheel *l* of 48, and this last wheel turns a pinion of six, on the axis of which is a broad flat piece of metal called the fly, seen edgewise at

The wheel *i* has eight pins projecting from it, and these, in succession, raise the tail of the hammer as the rotation of the wheel brings them to it. When the hammer is discharged, or frees itself from the pin, it is carried against the bell by the spring *z*; *u* is called the counter-spring, and is employed to prevent the hammer jarring against the bell.

We have now to examine the connexion between the going or watch part, and that which is employed in regulating the hammer-work.

Let *A* be a piece of brass cut down in twelve spiral steps in form of a snail, (from whence it takes its name) as in the figure; let this be fixed on the socket of the hour wheel; and *B* *G* *L* *F* the rack, with 14 teeth, turning on its centre *L*, having a spring *H* to force the end *F* upon the steps of the snail, *A*, when at liberty. The pin at *I* in the motion-wheel takes hold of the lifting-piece *D* *M* *K*; and the end *K* in rising, lifts up the hook *C*

which lies in the teeth of the rack, and rises until the teeth are disengaged from it; the end *F* then falls down, and stops against the steps of the snail *A*, which in the figure is at two o'clock.

The arbor of the third or gathering wheel *k*, shown in the preceding diagram, comes through the plate on which the pallet *E* *m* is fixed; a turn of which answering to one stroke of the hammer, gathers the rack up one tooth: 12 steps of the snail answer 12 teeth in the rack; and, when the gathering pallet *E* *m* has taken as many teeth in the rack as the number of the hour, the end *E* of the pallet stops against a pin in the rack at *G*, and is there at rest until the hook *C* is again lifted out of the teeth by the lifting-piece, as before.

When the hook *C* is lifted out of the teeth of the rack, the clock would strike continually, as the hook, being out of the teeth, prevents the rack being gathered up; but that the end *K* of the lifting-piece has a small arm which goes through the plate, and a pin in the wheel *t*, which stops against it in such a manner, that when the lifting-piece is suffered to fall by the pin *I* having gone past the pin in the rim of the wheel *t*, it is clear of the arm at the end of the lifting piece *K*; the wheel being then at liberty, the clock strikes until the gathering pallet *E* stops against the pin of the rack at *G*, as before. By putting a small string to the top-end of the spring *S*, or lifting-piece *M*, to come through the case, it may be made to strike the last hour at any time, except when on the warning.

A more simple contrivance for dividing the hours in a striking clock may now be examined;

it may, however, be proper to state, that this apparatus is seldom resorted to in the construction of a modern English clock, although the foreign mechanics still consider it well adapted for its intended purpose

The wheel *A* is in this case united to the barrel arbor, and as such revolves with it, bearing the locking-plate *B*. The arm *C* is attached to the detent *D*, so that when the extremity *C* drops into the notches in the plate, the striking train is stopped, by another arm on the detent *D* intercepting a pin in the warning wheel. A reference to the locking-plate will show that its divisions correspond with the hours of the day: the arm *C* indicating nine o'clock. In clocks of this description, the rack and its appendages are of course dispensed with.

In the year 1803, the Society for the Encouragement of Arts, &c. presented to Mr. John Prior of Nessfield, Yorkshire, a reward of thirty guineas on account of his contrivance for the striking part of an eight-days' clock. As this invention is likely to be useful, we shall describe it here. It consists of a wheel and fly, with six turns of a spiral line, cut upon the wheel, for the purpose of counting the hours. The pins below this spiral elevate the hammer, and those above are for the use of the detent. This single wheel serves the purpose of count-wheel, pin-wheel, detent-wheel, and the fly-wheel, and has six revolutions in striking the twelve hours. If we suppose a train of wheels and pinions used in other striking parts to be made without error, and that the wheels and pinions would turn each other without shake or play, then, allowing the above supposition to be true (though every mechanic knows it is not), Mr. Prior's striking part would be found six times superior to others, in striking the hours 1, 2, 5, 7, 10, and 11; twelve times superior in striking 4, 6, and 8; and eighteen times in striking 3, 9, and 12. In striking 2, the inventor purposely made an imperfection equal to the space of three teeth of the wheel; and, in striking 3, an imperfection of nine or ten teeth; and yet both these hours are struck perfectly correct. The flies in clocks turn round, at a mean, about sixty times for every knock of the hammer, but this turns round only three times for the same purpose: and suppose the pivots were of equal diameters, the influence of oil on them would be as the number of revolutions in each. It would be better for clocks if they gave no warning at all, but the snail piece to raise a

weight somewhat similar to the model Mr. Prior sent for the inspection of the Society for the Encouragement of Arts, &c.

The striking part of this clock is represented at fig. 3. *plate 2, of *HOROLORY*.

A, the large wheel, on the face of which are sunk or cut the six turns of a spiral.

B, the single worm screw, which acts on the above wheel, and moves the fly C.

D, the spiral work of the wheel A. The black spots show the grooves into which the dents drop on striking the hour.

E, the groove into which the locking piece F drops when it strikes one, and from which place it proceeds to the outward parts of the spiral in the progressive hours, being thrown out by a lifting piece H at each hour; the upper detent G being pumped off with the locking piece F, from the pins on the wheel A.

In striking the hour of 12, the locking piece, having arrived at the outer spiral at H, rises up an inclined plane, and drops by its own weight into the inner circle, in which the hour 1 is to be struck, and proceeds on in a progressive motion through the different hours till it comes again to 12.

I, the hammer-work made in the common way, which is worked by thirteen pins on the face of the spiral.

Fig. 4. K, the thirteen pins on the face of the spiral, which work the hammer-work.

L, the outer pins which lock the detent

M, the pump spring to the detent.

It may now be proper to notice the late James Ferguson's machinery for exhibiting the apparent daily motions of the sun and moon, and state of the tides, &c. The dial-plate of this clock is represented at fig. 1, of plate 2, of *HOROLORY*. It contains all the twenty-four hours of the day and night. S is the sun, which serves as an hour index, by going down the dial-plate in twenty-four hours; and M is the moon, which goes round in twenty-four hours, fifty minutes and a half, from any point in the hour circle to the same point again, which is equal to the time of the moon's going round in the heavens, from the meridian of any place to the same meridian again. The sun is fixed to a circular plate, as at fig. 2, and carried round by the motion of the plate, on which the twenty-four hours are engraven, and within them is a circle divided into twenty-nine and a half equal parts, for the days of the moon's age, accounted from the time of any new moon to the next after; and each day stands directly under the time (in the twenty-four hour circle), of the moon's coming to the meridian, the twelve under the sun standing for mid-day, and the opposite twelve for mid-night. Thus, when the moon is eight days old, she comes to the meridian at half an hour past six in the afternoon; and, when she is sixteen days old, she comes to the meridian at one o'clock in the morning. The moon M, fig. 1, is fixed to another circular plate of the same diameter with that which carries the sun; and this moon-plate turns round in twenty-four hours, fifty minutes and a half. It is cut open, so as to show some of the hours and days of the moon's age; on the plate below it that carries the sun, and across this opening at *a* and *b* are

two short pieces of small wire in the moon-plate. The wire *a* shows the day of the moon's age, and time of her coming to the meridian, on the plate below it that carries the sun; and the wire *b* shows the time of high water for that day on the same plate. These wires must be placed as far from one another, as the time of the moon's coming to the meridian differs from the time of high-water at the place where the clock is intended to serve. At London bridge it is high-water when the moon is two hours and a half past the meridian.

Above this plate that carries the moon, there is a fixed plate N, supported by a wire A, the upper end of which is fixed to the plate, and the lower end is bent to a right angle, and fixed into the dial-plate at the lowermost or mid-night twelve. This plate may represent the earth, and the dot at L, London, or any other place at which the clock is designed to show the times of high and low water.

Around this plate is an elliptical shade upon the plate that carries the moon M: the highest points of this shade are marked high-water, and the lowest points low-water; as this plate turns round below the fixed plate N, the high and low-water points come successively even with L, and stand just over it at the times when it is high or low water at the given place; which times are pointed out by the sun S, among the twenty-four hours on the dial-plate: and, in the arch of this plate, above twelve at noon, is a plate, H, that rises and falls as the tide does at the given place. Thus, when it is high-water (suppose at London), one of the highest points of the elliptical shade stands just over L, and the tide place, H, is at its greatest height: and, when it is low water at London, one of the lowest points of the elliptical shade stands over L, and the tide place H is quite down, so as to disappear beyond the dial-plate. As the sun S goes round the dial-plate in twenty-four hours, and the moon M, goes round it in twenty-four hours, fifty minutes and a half, the moon goes round so much slower than the sun, as only to make twenty-eight and a half revolutions in the time the sun makes twenty-nine and a half; and therefore the moon's distance from the sun is continually changing; so that at whatever time the sun and moon are together, or in conjunction, in twenty-nine and a half days afterwards they will be in conjunction again. Consequently the plate that carries the moon moves so much slower than the plate that carries the sun, as always to make the wire a shift over one day of the moon's age on the sun's plate in twenty-four hours.

In the plate that carries the moon, there is a round hole *m*, through which the phase or appearance of the moon, is seen on the sun's plate, for every day of the moon's age from change to change. When the sun and moon are in conjunction, the whole space seen through the hole *m* is black; when the moon is opposite the sun (or full) all that space is white; when she is in either of her quarters the same space is half black and half white; and different in all other positions, so as the white part may resemble the visible or enlightened part of the moon for every day of her age.

To show these various appearances of the moon, there is a black shaded space Nf , Ff , on the plate that carries the sun. When the sun and moon are in conjunction, the whole space seen through the round hole is black, as at N ; when the moon is full, opposite to the sun, all the space seen through the round hole is white, as at F ; when the moon is in her first quarter, as at f , or in her last quarter, as at l , the hole is only half shaded; and more or less accordingly for each position of the moon, with regard to her age.

Having seen that all clocks owe their motion either to a main spring, or the gravitating influence of some ponderous body, it will be evident that the moment the power is withdrawn, as in the act of winding, the wheels will cease to advance. To remedy the irregularity and variation in the time which this must of necessity produce, the annexed simple contrivance is occasionally resorted to:—

The small peg at the extremity of the lever is seen in the one case to rest upon the tooth of the wheel, while the dotted line represents it in its usual position. When the clock is wound the lever is raised, and, during the absence of its proper maintaining power, the pressure of a spring acting on the lever produces an equable motion in the train. There are a variety of other contrivances for this purpose; but the great simplicity of the one we have now described, although not entirely free from defects, fits it for general adoption.

As the period of winding a clock propelled by weights must of necessity depend on the length of the cord to which the weight is attached, it will be evident that any contrivance by which the line may be lengthened without increasing the fall must be advantageous to the machine. This desideratum is usually effected in a common clock, by introducing a pulley, represented at B , and, by means of this simple contrivance, the time of the clock is doubled. It may, however, be proper to add, that the weight must be increased in an equal ratio, as ten pounds attached to the pulley B , can only furnish a maintaining power of five pounds, or half that weight at A , so that a clock which is usually furnished with a weight of about fourteen pounds, in reality only requires seven to give motion to the train.

In all pendulum clocks, but more especially those that are employed for astronomical purposes, the greatest attention should be paid to the stability of the case or frame to which they are attached. The necessity of employing care in this respect may be best shown by reference to a curious fact furnished by the late Mr. Ellicott. It occurs in the Transactions of the Royal Society;

and he states, that a very excellent regulator was repeatedly stopped by the motion of a pendulum attached to another clock in the same apartment. At other times its rate was materially affected, and yet no apparent motion of the clock-case was observable. On this account it is, that the best regulators are usually attached to a firm support, altogether independent of the walls of the building in which they may be placed. A very ingenious apparatus has been suggested by Mr. Hardy, and rewarded by the Society for the Encouragement of Arts and Manufactures, which appears admirably adapted to detect the slightest oscillation that may occur. It consists of an inverted pendulum, and may be readily constructed by supporting a perpendicular wire by a slight steel spring, a movable weight being attached to a tube sliding on the wire. Should any vibration occur, the pendulum is immediately put in motion: and a graduated arc is sometimes attached to the upper part of the frame, which serves to mark the amount of oscillation.

The setting a clock into beat is usually effected by bending the crutch till the vibrations on each side are equal. To know when this is the case, it is merely necessary to mark the exact point occupied by the lower extremity of the pendulum when the ball is at rest. If it be then moved till the pallet escape, or, in plainer terms, till the clock is heard to tick, its extreme distance at that side will then be known. This must also be marked correctly; and if, on moving it in the opposite direction, it be found to describe a similar portion of a circle, it may then be considered as accurately in beat. If this should not be the case, the crutch must then be bent; or, in more complete machines, an alteration made by screws. It is also an essential condition, that the centre of suspension of the pendulum shall be exactly in the same vertical plane with the centre of the verge; for, if the pendulum spring happen not to coincide with a perpendicular line passing through the pivot-hole of the pallet's arbor, one half the arc of vibration will be greater than the other, even after the crutch is properly adjusted. An error of this kind must however be very obvious, and may be remedied by the eye.

In the early stages of the art clocks, as well as watches, were of very simple construction, and every artist was compelled from necessity to complete the machine he attempted to construct; but, in the present state of the business, it is divided into a great number of branches, and each, by devoting himself exclusively to that department, attains a greater degree of exactness and accuracy than he could possibly effect without such a division of labor.

The invention of pendulum clocks has been claimed, more especially, by Galileo and Huygens, neither of whom published their discoveries prior to 1649; and it will be found, by reference to the following extract, that it is to an English mechanic that we are really indebted for this valuable appendage of a modern clock:

‘The clock fixed in the turret of the said church, was the first long pendulum clock in Europe, invented and made by Richard Harris of London, A. D. 1641; although the honor of the invention was assumed by Vincenzo Galileo,

A. D. 1649, and also by Huygens in 1657. This plate is here affixed by Thomas Grignon, of this parish (Covent Garden), the son of the above Thomas Grignon, as a true memorial of praise

to those two skilful mechanicians, his father and Richard Harris, who to the honor of England, embodied their ideas in substantial forms that are most useful to mankind.'

CLOCK, *n. s.* Sax. *galukan*, to close; the gusset or ornamented work of a stocking.

His stockings with silver *clocks* were ravished from him. *Swift.*

CLOD, *n. s. & v. }* Goth. *klode*; Swed. **CLODDY**, *adj. }* *klot*. A lump of earth; the ground; any thing concreted together in a cluster, as particles of earth cleave to each other. Any thing vile, base, and earthy, as the body of a man compared to his soul. The adjective is applied to whatever is muddy, miry, mean, gross, base, and stupid. To clod is to coagulate together into concretions; and, when used in the active sense, to pelt with clods, or to cover with clods.

The glorious sun,
Turning with splendour of his precious eye,
The meagre *cloddy* earth to glittering gold.

Shakspeare.

The earth that casteth up from the plough a great *clod*, is not so good as that which casteth up a smaller *clod*. *Bacon.*

I'll cut up, as plows
Do barren lands, and strike together fints
And *clods*, the ungrateful senate and the people.

Ben Jonson.

The spirit of man,
Which God inspired, cannot together perish
With this corporeal *clod*. *Milton's Paradise Lost.*

Let us go find the body, and from the stream,
With lavers pure, add cleansing herbs, wash off
The *clodded* gore. *Id.*

Fishermen who make holes in the ice to dip up fish with their nets, light on swallows congealed in *clods* of a slimy substance; and carrying them home to their stoves, the warmth restoreth them to life and flight. *Carew.*

The vulgar! a scarce animated *clod*,
Ne'er pleased with ought above 'em. *Dryden.*

Byzantians boast, that on the *clod*,
Where once their sultan's horse has trod,
Grows neither grass, nor shrub, nor tree. *Swift.*

CLODIUS (Publius), a Roman of an illustrious family, but infamous for his licentiousness, avarice, and ambition. He committed incest with his three sisters, and introduced himself in woman's clothes into the house of Julius Cæsar, whilst Pompeia, Cæsar's wife, of whom he was enamoured, was celebrating the mysteries of Ceres, at which no man was permitted to appear. He was accused of this violation of human and divine laws; but, being made tribune, he thus screened himself from justice. Being the enemy of Cato, he procured him to be sent with prætorian powers, in an expedition against Ptolemy king of Cyprus, that by the difficulty of the campaign he might ruin his reputation, and destroy

his interest at Rome during his absence; but Cato, by his success, frustrated these attempts. He was also the inveterate enemy of Cicero, and by his influence obtained his banishment from Rome. He then wreaked his vengeance upon Cicero's house, which he burnt, and set his goods to sale; which, however, to his great mortification, no one offered to buy. He was some time after murdered by Milo.

CLODPATE, *n. s.* clod and pate. A stupid fellow; a dolt; a thickskull.

CLODPATED, *adj.* from clodpate. Stupid, dull, doltish, thoughtless.

My *clodpated* relations spoiled the greatest genius in the world, when they bred me a mechanick.

Arbutnot.

CLODPOLL, *n. s.* from clod and poll. A thickskull; a dolt; a blockhead.

This letter being so excellently ignorant, he will find that it comes from a *clodpoll*. *Shakspeare.*

CLOG, *n. s. & v. n. }* Probably from log,
CLOGGINESS, *n. s. }* a load or hindrance,
CLOGGY, *adj. }* A wooden shoe, which clogs or hinders in walking, while it protects the under shoe and the feet from wet. The idea of the verb is to impede motion by weight; to encumber with shackles; thence, to embarrass. It is occasionally used in the sense of coalesce, and to adhere; but improperly, as in such cases it is only a corruption of clod or clot.

But as he sought his logging, he lapped upon a whelp

That lay under a stayer, a grete walsh dog,
That bare about his neck a grete huge *clog*,
Because that he was spetuous and wold some bite;
The *clog* was longit about his nek for men sluld not wite,

Nothing, the dogges maister if he did eny harm,
So for to excuse them both it was a wyly charm.

Chaucer. Canterbury Tales.

Alone he rode, without his paragone,
For having flicht her bells, her up he cast
To the wide world, and let her fly alone,
He nould be *clogged*, so had he served many one.

Spenser.

Weariness of the flesh is an heavy *clog* to the will. *Hooker.*

They're our *clogs*, not their own; if a man be
Chained to a galley, yet the galley's free. *Donne.*

Since thou hast far to go, bear not along
The *clogging* burthen of a guilty soul.

Shakspeare.

You'll rue the time,
That *clogs* me with this answer. *Id.*

If you find so much blood in his liver as will *clog*
the foot of a flea, I'll eat the rest of the anatomy.

Id.

I'm glad at soul I have no other child
For thy escape would teach me tyranny,
To hang *clogs* on them. *Id.*

His majesty's ships were over-pestered, and *clogged*
with great ordnance, whereof there is superfluity.

Raleigh.
I did but prompt the age to quit their *clogs*,
By the known rules of ancient liberty.

Milton's Paradise Regained.
As a dog committed close

For some offence, by chance breaks loose,
And quits his *clog*, but all in vain,
He still draws after him his chain. *Hudibras.*

By additaments of some such nature, some grosser
and *cloggy* parts are retained; or else much subtilized
and otherwise altered. *Boyle's History of Firmness.*

In France the peasantry goes barefoot; and the
middle sort, throughout all that kingdom, makes use
of wooden *clogs*. *Harvey on Consumptions.*

Guns and pomatums shall his flight restrain,
While *clogged* he beats his silken wings in vain. *Pope.*

CLOGHER, a city and bishop's see of Ireland,
in the county of Tyrone, and province of Ulster.
In a very early age an abbey of regular canons,
dedicated to the Virgin Mary, was founded here.
St. Patrick is said to have presided over the
church of Clogher; and, having appointed his
successor, he resigned this government, and went
to Armagh, where he founded his celebrated
abbey. On the 20th of April, 1396, a dreadful
fire burnt to the ground the church, the two chapels,
the abbey, the court of the bishops, and
thirty-two other buildings. In 1610 king James
I. annexed this abbey and its revenues to the see
of Clogher. Clogher is seventy miles from Dub-
lin, and twenty west of Armagh.

CLOISTER, *n. s. & v. a.* } Welsh, *clás*; Sax.
CLOISTERAL, *adj.* } clauſter; Germ.
CLOISTERED, *part. adj.* } closter; French,
cloistre; Lat. *claus-trum*. A religious retirement;
a monastery; anunnery. A peristyle; a piazza.
To shut up in a religious house; to confine; to
immure; to shut up from the world.

Yeve me than of thy gold to make our *cloistre*;
Quod he, for many a muscle and many an oistre,
Whan other men han ben ful wel at ese,
Hath been our food, our *cloistre* for to rese.

Chaucer. Canterbury Tales.
Cloister thee in some religious house. *Shakspeare.*

Ere the bat hath flown
His *cloistered* flight, there shall be done
A deed of dreadful note. *Id. Macbeth.*

They have by commandment, though in form of
courtesey, *cloistered* us within these walls for three
days. *Bacon.*

It was of the king's first act to *cloister* the queen
dowager in the nunnery of Bermondsey. *Id.*

Upon this ground many *cloistered* men, of great
learning and devotion, prefer contemplation before
action. *Walton's Angler.*

Near to this gloomy *cloister's* gates,
There dwelt the blooming virgin Thwates,
Faire beyond measure, and an heir
Which might deformity make fair. *Marvell.*

Nor in a secret *cloister* doth he keep
These virgin spirits until their marriage day. *Davies.*

Some solitary *cloister* will I choose,
And there with holy virgins live immured. *Dryden.*

How could he have the leisure and retiredness of
the *cloister*, to perform those acts of devotion.

Atterbury.
The Greeks and Romans had commonly two *clois-
tered* open courts, one serving for the women's side,
and the other for the men. *Wotton's Architect.*

CLOISTER, in a more restrained sense, is used
for the principal part of a regular monastery,
consisting of a square, built around; ordinarily
between the church, the chapter-house, and the
refectory; and over which is the dormitory. The
cloisters served for several purposes in the ancient
monasteries. Peter of Blois observes, that it was
here the monks held their lectures: the lecture or
morality at the north side, next the church; the
school on the west, and the chapter on the east;
spiritual meditation, &c., being reserved for the
church. Lanfranc says, that the proper use of the
cloister was for the monks to meet in, and con-
verse together, at certain hours of the day. The
form of the cloister was square; and it had its
name claustrum from claudo, to close; as being
enclosed on its four sides with buildings. Hence,
in architecture, a building is still said to be in
form of a cloister when there are buildings on
each of the four sides of the court.

CLOISTRESS, *n. s.* from cloister. A nun;
a lady who has vowed religious retirement.

Like a *cloistress* she will veiled walk,
And water once a day her chamber round
With eye-offending brine. *Shakspeare.*

CLOKE, *n. s.* See **CLOAK**

CLOMB, *pret.* of to climb.

The sonne, he said, is *clomben* upon heven
Twenty degrees. *Chaucer. Cant. Tales*

Ask to what end they *clomb* that tedious height.
Spenser.

So *clomb* this first grand thief into God's fold.
Milton's Paradise Lost.

CLONAKILTY, a sea-port town in the
county of Cork, Ireland, situated in a bay of
this name. It is built in the form of a cross;
the church, a plain structure, standing on an
eminence. The bay is not convenient, and, in-
deed hardly safe. It is twenty miles south-west
of Cork, and has a good market for yarn.

CLONES, a town in the county of Monaghan,
Ireland. Here was formerly the abbey of St.
Tegernach, of royal blood, who removed to this
place the episcopal seat of Clogher. In 1207 the
town and abbey were destroyed by Hugh de
Lacie; but five years afterwards they were rebuilt.
In 1504 the bishopric was restored. It is ten
miles south-west of Monaghan.

CLONFERT, a city or village of Ireland, in
the county of Galway. An abbey was erected
here in the year 553; the church was also a ca-
thedral at that time, and constituted a bishop's
see. During the middle ages the abbey and town
were frequently plundered by the leaders of fac-
tions, as well as by the Danes. It is thirty-six
miles east of Galway.

CLOMEL, a borough in Ireland, in the
county of Tipperary, situated on the river Suir.
It is the assize town, has a barrack for two troops
of horse, and is governed by a mayor, recorder,

bailliffs, and town clerk; sending one member to parliament. The Suir is navigable from this town to Carrick and Waterford; and some trade is carried on in the woollen branch, particularly by the quakers, who are very numerous in this neighbourhood. There is a spring here of Spa water, that issues out of the side of a rising ground, which, however, is overlooked by a pretty steep hill, on that side of the Suir which is in the county of Waterford. In this town the celebrated Laurence Sterne was born. It consists of four cross streets, and has a spacious bridge of twenty arches over the Suir; the market-house is strong and well built; and there is a charter-school for children. A Dominican friary was founded at Clonmell in 1269, when Otho de Grandison also erected a Franciscan friary, the church of which was esteemed one of the most magnificent in Ireland. This town is very ancient, being built before the Danish invasion: it was formerly defended by a square wall. Oliver Cromwell, who found more resistance from this place than any other in the kingdom, demolished the castles and fortifications, of which now only the ruins remain. The Gothic church is still kept in good repair. Clonmell is nineteen miles south-east of Tipperary, and twenty-two W.N.W. of Waterford.

To CLOOM, *v. a.* corrupted from cleam. Sax. clæman, which is still used in some provinces. To close or shut with glutinous or viscous matter.

Rear the hive enough to let them in, and *cloom* up the skirts, all but the door. *Mortimer's Husbandry.*

CLOSE, *n. s., v. a., adj. & adv.* } Fr. *clos*;
CLOSELY, *adv.* } Teut. *klöse*;
CLOSENESS, *n. s.* } from Lat.

clausus. Any thing shut, as an enclosed field; also a termination, or that which shuts or encloses; a coming together; consolidation; a shutting up. The adjective conveys all the shades of meaning applicable to the other derivatives, we shall therefore furnish the definitions and illustrations of this, in addition to a few that establish the primary sense, as abundantly sufficient to explain both the literal and metaphorical applications of the entire word.

Certes I have now lived too long,
Sith I may not this *closer* kepe.
Al quick I would be dolven depe,
Yf any man shal more repayre
To this gardin for foul or fayre.

Chaucer. Romaunt of the Rose.

Ne left he hath sought,
But through the verger he hath sought
If he might finden hole, or trace
Wherethrough that me [I] mote forth by pace
Or any gap he did it close. *Id.*

I have a tree, which grows here in my *close*,
That mine own use invites me to cut down,
And shortly must I fell it. *Shakspeare.*

The admirable effects of this distillation in *close*,
which is like the wombs and matrices of living creatures.
Bacon.

The king went of purpose into the north, laying an open side unto Pekin, to make him come to the *close*, and so to trip up his heels, having made sure in Kent beforehand. *Id.*

The air, such pleasure loth to lose
With thousand echoes still prolongs each heavenly
close. *Milton.*

Speedy death,

The *close* of all my miseries and the balm. *Id.*
At every *close* she made, the attending throng
Replied, and bore the burden of the song.

Dryden's Fables.

Through Syria, Persia, Greece, she goes;
And takes the Romans in the *close.* *Prior.*

So in the Roman forum Carteus brave,
Galloping down, *closed* up the gaping cave.
Marvell.

Behold the picture! Is it like? Like whom?
The things that mount the rostrum with a skip,
And then skip down again. Pronounce a text,
Cry hem, and reading, what they never wrote,
Just fifteen minutes huddle up their work,
And with a well-bred whisper *close* the scene.
Couper.

Sweet as the downy-pinioned gale that roves,
To gather fragrance in Arabian groves;
Mild as the melodies at *close* of day,
That heard remote along the vale decay. *Beattie.*

In vain she seeks to *close* her weary eyes,
Those eyes still swim incessantly in tears,
Hope in her cheerless bosom fading dies,
Distracted by a thousand cruel fears,
While banished from his love for ever she appears.
Mrs. Tighe's Psyche.

Close to the glimmering gate he dragged his chain,
And hoped that peril might not prove in vain.
Byron.

What deep wounds ever *closed* without a scar,
The hearts bleed longest, and but heal to wear
That which disfigures it; and they who war,
With their own hopes, and have been vanquished,
bear
Silence, but not submission. *Id.*

The adjective is thus exhibited by Johnson.
We have supplied a few illustrations. Shut
fast, so as to leave no part open; as, a *close* box,
a *close* house.

We suppose this bag to be tied *close* about, towards
the window. *Wilkins.*

Having no vent; without inlet; secret; private;
not to be seen through.

Nor could his acts too *close* a vizard wear,
To escape their eyes whom guilt had taught to fear.
Dryden.

Confined; stagnant; without ventilation.

If the rooms be low roofed, or full of windows
and doors, the one maketh the air *close*, and not
fresh; and the other maketh it exceedingly unequal.
Bacon's Natural History.

Compact; solid; dense; without interstices or
vacuities.

The inward substance of the earth is of itself an
uniform mass, *close* and compact. *Burnet's Theory.*

The golden globe being put into a press, which was
driven by the extreme force of screws, the water made
itself way through the pores of that very *close* metal.
Locke.

Viscous; glutinous; not volatile.

This oil, which nourishes the lamp, is supposed of
so *close* and tenacious a substance, that it may slowly
evaporate. *Wilkins.*

Concise; brief; compressed; without exuberance or digression.

You lay your thoughts so close together, that were they closer they would be crowded, and even a due connection would be wanting. *Dryden's Juvenal.*

Where the original is close, no version can reach it in the same compass. *Dryden.*

Read these instructive leaves, in which conspire Fresnoy's close art, and Dryden's native fire. *Pope.*

Joined without any intervening distance or space, whether of time or place.

But yot the cause and root of all his ill,
Inward corruption and infected sin,
Not purged nor healed, behind remained still,
And festering sore did rankle yet within,
Close creeping twixt the marrow and the skin.

Spenser.

Was I a man bred great as Rome herself,
Equal to all her titles, that could stand
Close up with Atlas, and sustain her name
As strong as he doth heaven. *Ben Jonson.*

We must lay aside that lazy and fallacious method of censuring by the lump, and must bring things close to the test of true or false. *Burnet's Theory.*

Approaching nearly: joined one to another.

Now we sit close about this taper here,
And call in question our necessities.

Shakespeare.

Nature so herself does use
To lay by her wonted state,
Lest the world should separate,
Sudden parting closer glews.

Marell.

And as a child, when searing sounds molest,
Clings close and closer to the mother's breast;
So the loud torrent and the whirlwind's roar,
But bind him to his native mountain more.

Goldsmith.

Admitting small distance.
Short crooked swords in closer fight they wear.

Dryden.

Undiscovered; without any token by which one may be found.

Close observe him for the sake of mockery.
Close, in the name of jesting! like you there.

Shakespeare.

Hidden: secret: not revealed.
A close intent at last to shew me grace.

Spenser.

Some spagyrist, that keep their best things close, will be more to vindicate their art, or oppose their antagonists, than to gratify the curious or benefit mankind.

Boyle.

Having the quality of secrecy; trusty.
Constant you are,
But yet a woman; and for secrecy,
No lady closer.

Shakespeare.

Having an appearance of concealment; cloudy; sly.

That close aspect of his
Does show the mood of a much-troubled breast.

Shakespeare.

Without wandering; without deviation; attentive.

I discovered no way to keep our thoughts close to their business, but by frequent attention, getting the habit of attention.

Locke.

Full to the point; home.
I am engaging in a large dispute, where the arguments are not likely to reach close on either side.

Dryden.

Retired; solitary.

He kept himself close because of Saul. *Chronicles.*

Secluded from communication; as, a close prisoner. Applied to the weather, dark; cloudy; not clear. Applied to the mind, it signifies, to be reserved, impenetrable, covetous. The verb is sometimes used with an addition, as to close upon; to agree upon, to join in.

The jealousy of such a design in us would induce France and Holland to close upon some measures between them to our disadvantage. *Temple.*

To close with; to close in with. To come to an agreement with; to comply with; to unite with.

Intire cowardice makes thee wrong this virtuous gentlewoman, to close with us.

Shakespeare. Henry IV.

It would become me better than to close, in terms of friendship with thine enemies.

Id. Julius Cæsar.

There was no such defect in man's understanding, but that it would close with the evidence.

South.

He took the time when Richard was deposed, and high and low with happy Harry closed.

Dryden.

Pride is so unsociable a vice, that there is no closing with it.

Collier on Friendship.

This spirit, poured upon iron, lets go the water; the acid spirit is more attracted by the fixed body; and lets go the water to close with the fixed body.

Newton's Opticks.

Such a proof as would have been closed with certainly at the first, shall be set aside easily afterwards.

Atterbury.

These governours bent all their thoughts and applications to close in with the people, now the stronger party.

Swift.

To close with. To grapple with in wrestling.

CLOSE-BANDED, *adj.* In close order; thick ranged; or secretly leagued, which seems rather the meaning in this passage.

Nor in the house which chamber ambushes close-banded, durst attack me.

Milton.

CLOSE-BODIED, *adj.* Made to fit the body exactly.

If any clergy shall appear in any close-bodied coat, they shall be suspended.

Ayliffe's Pereragon.

CLOSE-HANDED, *adj.* Covetous.

Galla was very close-handed. I have not read much of his liberalities.

Arbuthnot on Coins.

CLOSE-HAULED, in navigation, the general arrangement or trim of a ship's sails when she endeavours to make progress, in the nearest direction possible, towards that point of the compass from which the wind blows. In this manner of sailing, the keel commonly makes an angle of six points with the line of the wind; but sloops and some other small vessels are said to sail almost a point nearer. All vessels, however, are supposed to make nearly a point of lee way when close-hauled, even when they have the advantage of a good sailing breeze and smooth water. The angle of lee way, however, increases in proportion to the increase of the wind and sea. In this disposition of the sails, they are all extended sideways on the ship, so that the wind, as it crosses the ship obliquely toward the stern from forwards, may fill their cavities. But, as the current of

winds also enters the sails in an oblique direction, the effort of it to make the ship advance is considerably diminished: she will therefore make the least progress when sailing in this manner. The ship is said to be close-hauled, because at this time her tacks, or lower corners of the principal sails, are drawn close down to her side to windward, the sheets hauled close aft, and all the bow lines drawn to their greatest extension to keep the sails steady.

CLOSE-PENT, *adj.* Shut close; without vent

Then in some *close-pent* room it crept along,
And smouldering as it went, in silence fed.

Dryden.

CLOSE QUARTERS, strong barriers of wood stretching across a merchant ship in several places; used as a place of retreat when a ship is boarded by her adversary; they are therefore fitted with loop-holes, through which to fire the small arms; they are likewise furnished with caissons, or powder-chests, fixed upon the deck, and filled with powder, old nails, &c., which may be fired at any time from the close quarters, upon the boarders.

CLOSE-STOOL, *n. s.* close and stool. A chamber implement.

A pestle for his truncheon, led the van;
And his high helmet was a *close-stool* pan.

Garth.

CLOSET, *n. s. & v. a.* from close. A small room of privacy and retirement; a private repository of curiosities and valuable things. To shut up, or conceal, in a closet; to take into a closet for a secret interview.

Chamber and *closet* denest of chastitie,
And named her brough of the deitie.

Chaucer.

Deepe, in the *closet* of my parts entyre,
Her worth is written with a golden quill,
That me with heavenly fury doth inspire,
And my glad mouth with her sweet prayses fill.

Spenser's Sonnets.

The taper burneth in your *closet*.
He would make a step into his *closet*, and after a short prayer he was gone.

Shakspeare.

Wotton.

The heat

Of thy great love once spread, as in an urn,
Doth *closet* up itself.

Herbert.

So where the neatest badger most abides;
Deep in the earth she forms her pretty cell,
Which into halls and *closets* divides;
But when the crafty fox with loathsome smell
Infects her pleasant cave the cleanly beast,
So hates her inmate and rank smelling guest,
That far away she flies, and leaves her loathed nest.

Fletcher's Purple Island.

He knew the seat of paradise,
Could tell in what degree it lies;
And as he was disposed could prove it
Below the moon or else above it,
What Adam dreamt of when his bride
Came from her *closet* in his side.

Hudibras.

He should have made himself a key, wherewith to open the *closet* of Minerva, where those fair treasures are to be found in all abundance.

Dryden's Dufresnoy.

He furnishes her *closet* first, and fills
The crowded shelves with rarities of shells.

Dryden's Fables.

CLOSTER SEVEN, a town of Germany, in the circle of Lower Saxony, and duchy of Bremen, memorable for a convention entered into by the duke of Cumberland and the duke of Richelieu, commander of the French armies in 1758, by which 38,000 Hanoverians laid down their arms, and were dispersed. It is nineteen miles south of Stade, and twenty-four N. N. E. of Bremen.

CLO'SURE, *n. s.* from close.

The act of shutting up.

The chink was carefully closed up: upon which *closure* there appeared not any change.

Boyle's Spring of the Air.

That by which any thing is closed or shut.

I admire your sending your last to me quite open, without a seal, wafer, or any *closure* whatever.

Pope to Swift.

The parts enclosing; enclosure.

O thou bloody prison!

Within the guilty *closure* of thy walls
Richard the Second here was hacked to death.

Shakspeare.

Conclusion; end. Not in use.

We'll hand in hand all headlong cast us down,
And make a mutual *closure* of our house.

Id.

CLOT, *n. s. & v. n.* Fr. *caillot*; from Lat.

CLOTTER, *v. n.* } *coagulation*. Probably,

CLOT'Y, *adj.* } at first, the same with

clod, but now applied to different uses. Concretion; coagulation; grume. To form clots or clods, to hang together, to congregate, to coagulate; as clotted cream; clotted blood. Johnson says to become gross, but gives no proof or illustration.

The *clotered* blood, for any leche-craft,
Corrumpeth, and in his bouke ylast,—
That neyther veine-blood, ne ventousing,
Ne drinke of herbes, may ben his helping.

Chaucer.

The white of an egg, with spirit of wine, doth bako the egg into *clots*, as if it began to poch.

Bacon.

The opening itself was stopt with a *clot* of grumous blood.

Wiseman's Surger.

He dragged the trembling sire,
Sliddering thro' *clottered* blood and holy mire.

Dryden's Æneid.

Where land is *clotty*, and a shower of rain soaks through, you may make use of a rool to break it.

Mortimer.

Huge unwiedly bones, lasting remains
Of that giantick race; which, as he breaks
The *clotted* glebe, the plowman lapply finds.

Philips.

CLOTAIRE I., king of France, was the son of Clovis and Clotilda. He began to reign in 511, and died at Compiègne in 561, aged forty-four. See FRANCE, HISTORY OF.

CLOTAIRE II., son and successor of Chilperic I. His father dying in his infancy, his mother maintained the kingdom for him, with great spirit and success, against the efforts of Childbert. After her death Theodebert and Thiuri defeated him; but he afterwards re-united the different kingdoms of France under himself. He died in 628.

CLOTAIRE, III. king of Burgundy, after the death of Clovis II. his father, who left him a minor. His mother Batilda, governed during his minority with great wisdom. He died in 670.

CLOTH, WOOLLEN.

CLOTH, *n. s.*
 CLOTHES, *plural.*
 CLOTHE, *v. a. & n.*
 CLO'THIER, *n. s.*
 CLO'THING, *n. s.*
 CLOTH-SHEARER, *n. s.*
 CLOTH-PRESSER, *n. s.*
 CLOTH-WORKER, *n. s.*

Ang.-Sax. clad, clæth. That which is woven, and now applied to any woven texture of whatever substance. The singular is applied to denominate the article as it comes out of the hands of the manufacturer. The plural is usually applied to the same article made into garments; and to garments in general: hence to whatever is used for covering and protection from outward injuries and unsightly nakedness. The different agents whose cognomen we have given are employed in the primary process of manufacturing and preparing the material; but not in the after process of forming it into apparel. To clothe is to invest, to adorn with dress, to furnish, provide with clothes, to cover.

Better it is to cast away thin here, than to cast away the sweetness of our Lord Jesu Crist, and therefore sayth Saint Poule, *clothe you*—as they that ben chosen of God in herte, of misericorde debonairete, and swiche maner of *clothing* of which Jesu Crist is more plesed than with the heres or ha-bergeons. *Chaucer. The Persones Tale.*

The third had of their wardrobe custody, In which were not rich tyres, nor garments gay, The plumes of pride and wings of vanity, But *clothes* meet to keep keene cold away, And naked nature seemly to aray; With which bare wretched wights he daily clad, The images of God in earthly clay; And, if that no spare *clothes* to give he had, His owne cote he would cut, and it distribute glad. *Spenser.*

He with him brought Preyne, rich arrayed In Claribellae's *clothes.* *Id.*

Take up these *clothes* here quickly; carry them to the laundress in Datchet mead. *Shakspeare.*

I answer you right painted *cloth*, from whence you have studied your questions. *Id.*

Who fears a sentence, or an old man's say, Shall by a painted *cloth* be kept in awe. *Id.*
 Care no more to *clothe* and eat. *Id. Cymbeline.*

The *clothiers* all, not able to maintain
 The many to them 'longing, have put off
 The spinsters, carders, tilters, weavers.

Id. Henry VIII.

My father is a poor man, and by his occupation a *cloth-shearer.* *Hakewill on Providence.*

The king stood up under his *cloth* of state, took the sword from the protector, and dubbed the Lord Mayor of London knight. *Sir John Hayward.*

I'll make the very green *cloth* to look blue.

Ben Jonson.

If thou beest he; but O how fallen! how changed
 From him, who in the happy realms of light,
Clothed with transcendent brightness, did'st outshine
 Myriads though bright! *Milton.*

At length by wonderful impulse of fate
 The people call him home to help the state,
 And, what is more, they send him money too,
 And *cloath* him from head to foot anew. *Marvell.*

A costly *cloth* of gold.

Drayton.

The Spaniards buy their linen *cloths* in that kingdom. *Sieft.*

Your bread and *clothing*, and every necessary of life, entirely depen upon it. *Id.*

They leave the shady realms of night,
 And *clothed* in bodies, breathe your upper light. *Dryden.*

Gazing on her midnight foes,

She turned each way her frightened head,

Then sunk it deep beneath the *clothes.* *Prior.*

Let both use the clearest language in which they can *clothe* their thoughts. *Watts on the Mind.*

Nor let, like Nævius, every error pass;
 The musty winc, foul *cloth*, or greasy glass. *Pope.*

Embroidered purple *clothes* the golden beds.
Pope's Statius.

True Witney broad-*cloth* with its shag unshorn,
 Unpierced, is in the lasting tempest worn. *Goy.*

With superior boon may your rich soil

Exuberant nature's better blessings pour

O'er every land, the naked nations *clothe,*

And be the exhaustless grauy of a world. *Thomson.*

Who toils for nations may be poor indeed,
 But free, who sweats for monarchs is no more
 Than the gilt chamberlain, who *clothed* and fee'd.

Stands sleek and slavish, bowing at his door. *Byron.*

CLOTH is a cotton, linen, or woollen manufacture. That, indeed, which, among the inhabitants of Otaheite, and other barbarous people, is made of the barks of trees, has been sometimes treated under this term; but it has already engaged our attention sufficiently under the word BARK, which see. On the other hand, hair, silk, and the ductile and precious metals of silver and gold have been, in highly civilised countries, wrought into cloth.

But the three divisions of this extensive species of manufacture, which we have named, will embrace its principal and more common application. For HAIR-CLOTH, see that article; for cloth made of silk, see SILK MANUFACTURE; and for cloth of gold and silver, see TISSUE.

Cotton, linen, and woollen cloths, alike undergo three common processes from the raw material, to the complete and finished piece of goods.

1. They are prepared in various ways until they form yarn. 2. They are woven into cloth; and 3. They are bleached, dyed, printed, glazed, &c. to various stages of beauty and perfection. Under the names of the respective materials, COTTON, FLAX, and SILK, will the very distinct methods of preparing those materials be treated. Our attention in this article will be directed to the different operations by which our staple manufacture of woollen cloth is conducted after the sorting of the wool, for which see WOOL; and, with the exception of WEAVING, (an operation sufficiently important to require a distinct article) this finally receiving the name of *cloth*, in distinction from linen, cotton, and silk goods.

Cloths are of various qualities, fine and coarse. The following general criteria of the goodness of cloth, have been often given, viz. 1. That the

CARDING ENGINE.

STEAM-ENGINE.

PLATE II. WOOLLEN.
via Machinae

wool be of a good quality, and well dressed. 2. It must be equally spun, carefully observing that the thread of the warp be finer and better twisted than that of the woof. 3. The cloth must be well wrought, and beaten on the loom, so as to be everywhere equally compact. 4. The wool must not be finer at one end of the piece than the rest. 5. The lists must be sufficiently strong, of the same length with the stuff, and must consist of good wool, hair or ostrich feathers; or, what is still better, of Danish dog's hair. 6. The cloth must be free from knots and other imperfections. 7. It must be well scoured with fullers' earth, well filled with the best white soap, and afterwards washed in clear water. 8. The hair or nap must be well drawn out with the feazel, without being too much opened. 9. It must be shorn close without making it thread-bare. 10. It must be well dried. 11. It must be tenter-stretched to force it to its just dimensions. 12. It must be pressed cold, not hot-pressed, the latter being very injurious to fine woollen cloth.

This manufacture we shall now more particularly consider in its processes. 1. Of preparing the wool, after it has been sorted for the weaver. 2. Of finishing the cloth after it is taken from the loom.

1. *Of preparing the wool after it has been sorted.*—The best wools for the manufacturing of white cloth, intended for dyeing, are those of England and Spain. Spanish wool, as it arrives in this country, has generally some part of the marking pitch still adhering to it in the bale, which must be carefully cut or picked off; and it is frequently so hardly pressed together in the bag, that it requires to be opened out by beating. Until recently it was the practice to beat the wool with rods, in order to shake out the dust and open the staples; but this is now principally done by an opening machine with long coarse teeth, called a devil, or wool-mill, described farther onward. English wool is generally cleaned from pitch marks or other extraneous substances by the wool-sorter, and left by him in a proper condition to commence the process of cloth-making.

In Hampshire, and the west of England, it is now most commonly scoured, by putting it into a furnace containing a liquor composed of three parts of water and one of urine; and after it has been well stirred therein, and the grease it contains dissolved, it is taken out, drained, and washed in running water. In Yorkshire this excellent practice is said to be omitted in regard to wools intended for white cloths; and manufacturers who dye their own wool frequently put it into the dyeing-vat unscoured; a process which, while it enables him to make a greater weight of cloth from his wool, injures the brightness of the colors. It also makes it needful that the oil afterwards used should be increased one-third at least; and gives a general want of cleanliness and comfort to the whole manufacture.

Berthollet states that in this operation, properly conducted, one-fourth of the previous weight of the wool is taken off; and he attributes to the ammonia of the putrefied urine its detergent quality. Vauquelin having analysed

the grease, or yolk, as it sometimes is called, thus discharged, found it to consist of

1. A soap, with a basis of potash, which formed its chief parts.
2. Carbonate of potash, in small quantity.
3. A notable quantity of acetate of potash.
4. Lime.
5. A little muriate of potash.
6. An animal matter, which yields its odor.

He thinks the ammonia contained in the putrefied urine not to be conducive to its action, and advises the use of ordinary soap as better fitted to procure the desired whiteness to wools.

When wool is dyed in the fleece, or without being spun, it is now ready to be committed to the dye-furnace; and this is principally the case when it is to be employed for forming cloths of mixed colors; otherwise it is dyed after being spun. But it is most commonly dyed in the form of cloth.

In the making of superfine cloths, in Hampshire, the wool, after dyeing, is again washed, well dried and beaten with rods on wooden hurdles, to free it from the dye-stuff, which still hangs about it; or this effect is produced by putting it into a wool-mill, formed of a four-flapped vane or fan thinly set with iron spikes, and swiftly revolving within a hollow cylinder of small wooden rods or staves; sufficiently wide apart to suffer the dust to fall through, as the wool becomes separated by the motion of the fans. It is now once more carefully picked, in order to take out the locks which are unevenly dyed, and also the lint, and other filth with which wool in this state abounds. In the manufacture of mixed cloths, wool of the different colors, being weighed out in their requisite proportions, are first shaken well together; they are then further mixed, by being well turned in the wool-mill, and, by being afterwards twice passed through the scribbling engine instead of once, they are generally found to be sufficiently intermixed.

The nature of wool, as a species of hair, has been well illustrated by M. Monge in his Observations sur le Mécanisme du Feutrage, Ann. de Chimie, tom. vi. 'The surface of all these objects,' he observes, 'is formed of rigid plates, superposed or tiled from the root to the point, permitting progressive movement towards the root, and resisting a similar movement towards the point. This conformation is the main cause of the tendency to felting, which the hairs of all animals in general possess.'

But this conformation, it is clear, must be an obstacle to the spinning of wool, and the fabrication of cloth. Their fibres, therefore, are now coated with oil, which, by filling up the cavities, renders their asperity less perceptible in these operations, just as a film of oil is put upon a smooth file when we wish to render it still smoother. For fine cloths, Gallipoli, or olive oil, is principally used: and rape oil for coarse cloths. In still coarser goods, and where color is not an object, fish-oil is sometimes employed; but if the latter remain in the wool or cloth, it is subject to a fermentation injurious to the cloth, and turns it brown. Combustion has even sometimes been known to take place from

it. Some of the Yorkshire manufacturers make use of a mixture of soap and water with oil, which answers, in moist weather, and, if the wool be immediately carded and spun, very well; but the mixture evaporates, if it remain some time unwashed, or the weather become hot.

In oiling, the wool must be sprinkled as evenly as possible. They spread it, for this purpose, on a floor, in Hampshire, beating it in with heavy rods, and use, for superfine cloth, about three pounds of olive oil to twenty pounds of wool. In Yorkshire they reckon six gallons, or a peck, as the proper quantity for fine cloths, and use the wool-mill to assist in its more equal distribution.

This machine consists of a species of cylindrical drum, from three feet, to three feet and a half long, and two and a half to three feet diameter, enclosed with its rollers in a close box or case, in which is a door let down by a hinge. Its circumference being furnished with teeth or spikes, immediately above are five small rollers, furnished with similar teeth: and the machine is made, it is said, to revolve 300 times in a minute. The teeth of the rollers and those of the drum intersect each other, as they all turn round; and the teeth of the five small rollers also intersect each other. The door being opened, or turned down into a horizontal position, about a pound weight of wool is laid upon it at once, and is brought, by its being closed, within reach of the teeth of the cylinder, which take and carry it upwards, so as to work it between the teeth of the cylinder, and those of the five rollers. This opens and separates the matted fibres. Close below, and fitted to the cylinder, is a grating of wooden rods, through which the dust and dirt are carried off. When the door is re-opened, the cylinder throws out the wool in an instant; but sometimes two doors are placed on opposite sides of the machine; one to receive the raw wool, and the other to discharge it when the operation is finished. Coarse goods are passed through this mill; to break the mats of the raw wool and render it light; a second time after it is dyed; a third time, to mix the different sorts together; and lastly, after they are oiled, to spread the effects as we have stated.

The scribbler, a kind of rough carding machine, is now resorted to, to break down the longer fibres, and to lay them straight and parallel. It is the same in principle with the carding machine, hereafter described; and, like the above, consists, 1. Of a large cylindrical drum; but covered on the surface with sheets of leather stuck full of projecting wire-teeth, or card-wires, which, as the cylinder is turned, feed themselves with the wool: 2. Of several other smaller cylinders, called workers and clearers, fixed around the great cylinder in pairs. The wool is taken by the teeth of the workers from the great cylinder, and given to the clearers, which return it again to the great cylinder. It is then transferred to another worker, and by its clearer given back again to the great cylinder, and so on. While the teeth of the different cylinders do not actually touch each other, they revolve so near, that the fibres of the wool which the teeth of one card contains are caught by the teeth of the other

card, and drawn out a very few at a time, which renders the wool light and open. 3. When it has passed between three or four pairs of workers and clearers, it is taken up by the *doffer*, a small cylinder, which turns round very slowly. 4. From it the wool is stripped off by a steel comb, which is placed parallel to its axis, and moved rapidly up and down by a crank. The comb, in ascending, does not touch the doffer; but only as it falls down. The successive portions thus combed off, finally hang together in a thin fleece or web; received in a basket from the machine. Scribbling is repeated twice or three times before the wool is completely disentangled and fit for carding, which, as we have stated, is only an improved operation of the same kind.

But great attention has been bestowed on the carding engine. We shall best illustrate it by the accompanying plate. M, M, M, M is the frame work of the machine which is of wood or cast iron, the arched part receiving the screws, which support the cylinders or workers and clearers fixed round it. The workers A are larger, and turn slower, than the clearers B; but all work against the cards of the great cylinder, and each is worked upon its clearer. C is the large cylinder turned by an endless strap applied upon a pulley at one end of its axis. It performs 100 revolutions per minute, and is from thirty to thirty-six inches in diameter. D is a roller-bowl, as it is called, or a cylinder of wood, fluted shallow, and moved by a pulley E, connected with another endless strap moving round a second pulley F, on the cogged wheel G. The lower hemisphere of this roller-bowl is circumscribed with a fluted shell, to catch the wool that falls from the doffer on the left of it. H is a cog-wheel receiving motion from the pinion of a pulley I, turned by an endless band moving on the central pulley of G. This wheel is connected at top with a pinion fixed on the axis of the large cylinder.

The wool having been scribbled is spread upon the feeding-cloth K, an endless sheet stretched over two rollers, on the axis of one of which moves the wheel H. It is taken off the sheet, between a pair of feeding-rollers about two inches and a half diameter within the frame, and clothed with cards laid on in spiral fillets. They are moved by toothed pinions, on the axis of the cloth-roller, rather quicker than the feeding-cloth, and, in the most complete view of the machine we can give, are concealed by other parts of it. These rollers deliver the wool to the cylinder L, about nine inches in diameter, which works against and communicates it to the great cylinder. It is now conveyed to the five workers, and clearers, embraced by the chair N passing under a wheel fixed in G, shown under the frame work, but this chain only moves the three workers A, which revolve once in about four revolutions of the great cylinder.

The clearers both card the wool on the workers, as well as that on the cylinder, and are moved by the band O passing over a wheel eight inches and a half in diameter fixed on the extremity of each of their axes, and communicating with a wheel twenty-two inches in diameter, fixed on that of the great cylinder. The cylinder turns about

three times and a half as fast as they: this same strap moves the carrier L. It also turns the fly P, moving the same way as the surface of the great cylinder, but about half as fast again. This fly is designed to raise and lighten the wool on the surface of the cylinder (not to take it off), so that the doffer, which we have already mentioned, Q, may act upon it the more effectually. This is a cylinder of about fourteen inches diameter, covered with cards about four inches wide, and moving round at the slow rate of about one-thirtieth of the pace of the great cylinder: it is turned by a band connected with the axis of the roller-bowl: a comb which works against these cards cannot be seen. It is supported by rods screwed to it at each end, guided by two horizontal levers. The lower ends are jointed on small cranks formed on an horizontal axis at the lower part of the frame, and put into very quick motion by a strap, from a pulley at the bottom. Each revolution of the cranks causes the comb to rise and fall about two inches; when it descends, its edge-teeth act on the surface of the doffer cards, so as to take out the wool and drop it slowly into the shell of the roller-bowl. The revolutions of this bowl within its shell rolls the wool between them into a straight cylindrical shape, called a carding; these cardings are yielded from between the roller-bowl and its shell, upon a flat table R, in portions there exhibited. An endless cloth covers this table. It is stretched over horizontal rollers, and carries the cardings away to the slubbing machine or biley, by means of the motion it receives from the pulley S, which is fixed on the axis of one of the rollers.

The *slubbing machine* is a species of spinning engine performing the preparatory operations of reducing and clensating the cardings, and giving them a slight twist. They are then called rovings or slubbings. This was once accomplished by hand on the common hand spinning-wheel, then machines were invented, by means of which a number of slubbings could be drawn out together; but the aid of hands being required for joining the rolls or cardings of wool, they were found of little service, and have universally given way to the modern machine, which we shall now endeavour to describe.

It is a wooden frame, within which passes to and fro a moveable carriage, containing a number of perpendicular spindles, put into rapid motion by a long cylinder, and a band from a pulley affixed to each spindle. These spindles are placed perpendicularly, in a frame at about four inches from each other; their lower extremities are pointed, and turning in sockets; and the upper half projecting above the frame. On the lower part a small pulley or whirl is fixed, to receive the band from the horizontal cylinder (about six inches in diameter), and a little longer than the row of spindles: it is placed before them with its centre at a lower position than the row of whirrs. The cylinder receives motion by a pulley at one end, with an endless band from a wheel, made like the large wheel used in spinning wool by the hand. This wheel is situated at the outside of the frame of the machine, and its axis supported by upright standards erected from the

carriage; the wheel is turned by the left-hand of the spinner, applied to a winch, and gives motion to the cylinder, which turns all the spindles at once. The operations of the spinning jenny are so very similar, that our plate of that machine will fully enable the reader to comprehend this. The discretion of the spinner regulates the degree of twists given to the slubbings, which depends both on the rapidity with which the wheel is turned, and the corresponding quickness with which the carriage is drawn out, as well as on the fineness of the wool and the length of its fibre.

For fine shawl yarns, a machine called the mule, similar to the cotton mule, is often employed, see COTTON MANUFACTURE, the slubbing passing through rollers which assist in drawing out the thread smaller and more regularly.

In the *spinning jenny* the slubbings are again spun and prepared for the loom. Its parts are similar to those of the preceding machine, only differently placed. Our plate II. CLOTH, WOOLLEN, contains a view of this important modern invention. F, F, F, is the frame work, at the end of which the spindles *s, s, s*, are placed, about four inches apart. As in the slubbing machine their lower ends turn in caps or sockets of the cross-rail, and near the middle they are held up by brass collars fixed on another rail. Towards the lower end they receive an endless strap round their respective pulleys, communicating with the great roller A, which is generally made of tin plate, and receives its motion from the band B, which passes the great wheel C C. The moveable cross-rail D is morticed into blocks of wood, and runs on the general frame by means of small wheels or castors. It can be moved to and fro from six to seven feet. The underside is furnished with narrow notches for the slubbings to pass through, opposed to the projecting pieces, of a parallel cross-rail E, so as to form a clasp which confines the slubbings in the notches when the lower rail is raised up. They can however pass freely through the notches when the lower rail is down. This rail is limited in its movements up and down a small space by staples, which project downwards from the upper rail. Its rising and falling is effected by small cords fastened to it at about every three feet, and conducted over small pulleys in the substance of the upper rail, which are all attached to a handle, situated over the middle of the upper rail, beneath an arched bar G. This the spinner holds in her left hand, while the right is employed in turning the wheel; and by the fingers of her left hand she raises up the lower rail, and draws it close to the upper. In this position it is returned at pleasure by a small spring-catch, and clasps the slubbings in the notches, through which they pass; when the spring-catch is pushed back the lower rail falls, and releases the slubbings. An inclined frame H, receives the cops of the slubbings to be spun. They are rolled on iron wires, placed in two rows, each containing half as many cops as there are spindles. Each slubbing is conducted through a notch in the clasp, and thence it now proceeds nearly in a horizontal position to the spindles *s, s, s*. The yarns having been drawn out and twisted are wound on the spindles in balls.

It is a wire used for bearing down the thread from the points of the spindles, and attached to a horizontal rail, which is supported on pivots at its ends, close to the row of spindles. A pulley K receives one end of this rail, and a short lever at the other is hid by part of the framing. Between the pulley K and the lever the wire is extended, and by turning round the rail the wire receives a perpendicular motion. This the spinner can communicate when at her business by the cord L, the end being made fast to a pin at M, and the pressure of her finger on a small trigger in the handle G. A counterweight to bring it back to its first position is suspended from the pulley K.

The spinning jenny is worked by a female (generally) standing within the frame and turning the wheel with her right hand, while the cross-rail D is managed by her left. We have described the manner in which the slubbings are drawn between the upper and lower rails of this part of the machine; they are drawn off the balls at H, when the clasp retires from the spindles, until a certain length of each is extended nearly in an horizontal position between the spindles and the clasp. The motion of the wheel then twists those parts of the slubbings which are extended, and first in a contrary direction to the twist of the slubbing. They are now wound up upon the spindles, previously to drawing out a fresh portion of each slubbing, in order to spin it in the same manner. For this purpose they are pushed down upon their respective spindles, by pressing the trigger which moves the wire L; and the motion of the wheel is applied while the carriage and clasp are pushed home towards the spindles. Arrived there, the thread is finished and wound up.

The art of using the jenny consists in drawing out the carriage with a movement correspondent to the rapidity with which the spindles give the twist, or rather untwist, to the slubbing; for the principal extension of the thread is effected whilst this is going forward: as also in giving an equal degree of twist to the whole thread. The yarn that is intended for the warp, we should add, requires that the spindles be turned for a time after the thread is extended to its full length; but for the yarn which is to be used as weft, it is different: the whole of the twist is given during the extension of the thread, and none afterwards; this renders the weft softer than the warp, because in the cloth the weft appears more on the surfaces than the warp, and it is principally the felting and interlacing of the fibres of the weft that will form the surface of the cloth.

Warping, which is our next process, is performed by mounting the yarn on wires in a frame, and drawing it off the coppings, so as to combine a number of them together. The warping-mill, which is now generally used, is a large reel, with an horizontal axis; the ends of the threads in fact are made fast to the reel, which is turned round, and it draws off the threads upon its own circumference. To prevent them overlaying one another, they are guided through an eye or ring affixed to a slider, moved along a wooden rail, in a direction parallel to the axis of the reel, by a cord that winds round one end of the axis.

After this process the warp is *scoured* with urine to cleanse it from the unctuous matters adhering, and sized in a cauldron, about a dozen yards at a time: it is then dried and stretched in the open air: and when dry it is transferred from the field to the loom. The weft-yarn is wound off the jenny-cops on the quills or bobbins which are afterwards used by the weaver.

For the loom employed, and its most recent improvements, we refer the reader to the article *WEAVING*. It will be sufficient here to observe that the width of the cloth returned from that process is expected to correspond with the number of the yarns, so that 3000 common threads will make a piece of coarse cloth 103½ inches wide; and 100 yards of fine cloth is expected to be produced from about 2960 threads: the weft averages about one pound per yard: and sixty-two yards of cloth is considered a fair return for sixty-five yards of yarn.

The cloth must now be scoured in the piece, preparatory to felting: and for this purpose it is taken to the fulling-mill, which ordinarily consists of a pair of stocks in wooden hammers, suspended in an inclined position, and the heads lifted up and down by cogs or tappets, fixed on the axis of a water-wheel. When the cogs are removed by its revolutions from under the hammers, they fall by their own weight, and strike the piece of cloth, which is contained in a wooden cistern or trough. This both causes a continual circulation or turning round of the piece of cloth in the trough, and effects the scouring or washing it by continually bending or folding it in a fresh direction. It is now extended on the well known tenter-hooks, fixed in horizontal rails, attached to vertical posts, one line of the rails being fixed and the other moveable, by means of pins and holes.

Milling is another operation performed by the action of the hammer of the fulling-mill. To a piece of cloth thirty-one yards long, three pounds of soap are allowed at this stage, and it is worked in the mill about two hours, then soaped anew twice, and returned to the mill for about the same time, so that it undergoes the operation three times.

‘The operation of fulling woollen stuffs, has so close a relation with felting,’ says M. Monge, a writer we have before quoted, ‘that we cannot dispense with entering into some details on this subject. The roughness with which the fibres of wool are bristled at their surface, and the disposition which the fibres have to take a progressive movement in the direction of the root, is an obstacle to the spinning of wool and to the fabrication of stuffs. In order to spin the wool, and afterwards weave it, we are obliged to coat all the fibres with a film of oil. When the piece of stuff is manufactured it must be deprived of this oil which gives it a disagreeable color, and constitutes a kind of filthiness which would be an obstacle to dyeing. For this purpose it is carried to the fulling-mills, where it is beaten with mallets in a trough filled with water, through which clay (fuller’s earth) has been diffused. The clay combines with the oil, which it renders soluble in water; both are carried off by the fresh water which the machine itself brings

upon it; and at the end of a certain time the stuff is scoured.

But scouring is not the only object of the fulling. The alternate compressions which the beetles exert on the piece of stuff, especially when the scouring is well advanced, produce an effect analogous to that of the hand-pressure of the latter. The fibres of wool which compose one of the threads of the woof, or of the warp, take a progressive movement, get introduced into one of the neighbouring threads, then into those which follow, and soon all the threads both of the woof and warp are felted together. The stuff, after having suffered a narrowing in its two dimensions, partakes of the nature both of web and felt; it may be cut without being liable to open out its threads, and there is no necessity for hemming the different pieces which enter into the composition of a garment. If it be ordinary knit wool, the stitch is no longer apt to run when it happens to escape. Lastly, the threads of the woof and the warp being no longer so well defined, or so distinct from each other, the stuff, which in other respects is thickened, forms a warmer clothing.

After milling the piece is again stretched on the tenter-hooks, and only now awaits the finishing operation that forms its surface. To effect this it is generally first dressed with teasels, a species of thistle; the part used is the ball, or ear, which contains the seed of the *dipsacus fullonum*. Scales project from this ball, with elastic points turned downward. They are fixed in a small frame which is provided with a handle eight or ten inches long, having a small stick, about eight inches long, passed through it at one end. This stick is split into two at each end nearly all its length. Near the middle there is another similar stick which is passed through the handle; the two split sticks being parallel to each other. The space between them is filled with teasels, jammed in very fast, as also in their split parts, where they are secured by strings extended between the ends, and twisted until they draw the sticks and bind the teasels forcibly together. The whole forms a tool resembling the curry-comb, and which is used in a similar manner, to draw out, by scratching, all loose ends of the fibres of the wool. Two men hold the teasel-frame and work the cloth as it hangs up in a vertical position, drawing it down in portions as they proceed. The first time the cloth is thus dressed it is wetted, and worked three times over in that state by strokes, in the direction of its length, then it is worked again three times in the other direction. But more scientific modes of accomplishing this part of the manufacture have of late been adopted in Yorkshire. Plate III. CLOTH, WOOLLEN, represents a gig-mill, very commonly used in the manufactories. On F, a wooden frame is erected, a cylindrical engine C, over which the cloth is conducted, and which revolves with the pulleys PP, receiving an endless band from the upper wheel W. The pulleys are, one fixed and one loose for the straps to turn upon freely, that the machine may be the more readily put in motion or stopped. W, communicates with a barbed wheel X, by means of a strong iron shaft, and is moved by the great wheel G, connected with any convenient first

mover. Round the cylinder, C, are teasels secured in boxes or frames. One end of the piece of cloth, is wound over the roller R, at the bottom of the frame, and the other end of the piece is wound on the rollers r, r. The roller below is moved by a bevelled wheel s, and fixed on the extremity of the axis of the cylinder, having a pinion at each end. The upper rollers r, r are both turned by a large spur-wheel which works in a smaller wheel, on the end of the cylinder; one roller is mounted over the other, like the two rollers of a flattening-mill, and pressed together by screws with sufficient force to draw the cloth between them. The piece of cloth, when brought to the machine, is laid down on a board on the ground before the machine, and one end is passed under the roller R, which is merely to guide it; then it is carried over the cylinder, as at O, and introduced between the pair of rollers at top, which draw it slowly forwards; from these it turns upwards, and is extended horizontally over two other rollers suspended from the ceiling. Quitting these it descends perpendicularly, and is gathered on the ground in folds on a board or bench. To make the piece pass a second time, or as many times as is required, through the machine, the two ends of it have only to be sewed together, and it will circulate continually over the machine. B is a perforated pipe which conveys water to the machine for wetting the cloth. The teasels are picked in the course of these operations and cleaned by children. Various substitutes of metallic teeth &c. have been suggested, but none seem to have answered on a considerable scale.

The wool of the cloth is raised by the preceding process, so as to stand up all over its surface in a loose fur: the last operation is shearing, or cropping this fur. The clothiers' shears, for performing this by hand, consist of two very large flat steel blades, united together by a stem, which is bent into a circular bow, and sufficiently flexible to allow one of the blades to be moved upon the other, but not in parallel planes like scissors, for when the one blade is laid flat upon the cloth the plane of the other will be inclined to it at about an angle of forty-five degrees. The spring of the bow, however, is so set as to press the two edges into contact. The edges of the two blades are not parallel to each other, but inclined, so that the edge of the upper blade crosses the edge of the lower blade, and bears upon the flat surface of that blade, at the end nearest to the bow, whilst the other end of the edge of the upper blade is removed over the edge of the lower blade, thus leaving an interval between the two edges when the shears are open. In this state, the shears being open, if the lower blade is laid flat upon the surface of the cloth, the nap or wool, which is to be removed by the cropping, will stand up above the edge of the lower blade, in the interval between the two edges; then, if the blades be forced together, the edge of the upper blade will pass or cross over that of the lower, and cut away all the wool which projects above the edge of the lower blade. The contact of the cutting-edges begins at the end nearest to the bow, and proceeds regularly to the other, because, as before mentioned, the edges are not parallel. The blades open or re

turn to their former position by the elasticity of the bow, but in order to make the cut they are closed by means of a handle or lever, which is fitted or lodged on a round part of the stem of the bow, so as to play thereupon as upon a centre. A double cord is made fast to the lever or handle near to this centre, and the other end of the cord is fastened to a block of wood, which is screwed to the flat of the lower blade, and rises up to a proper height. By depressing this handle the shears are closed, and make their cut with the greatest facility, the elasticity of the bow returning the handle. The manner of cropping is:—Let the piece of cloth be laid down in folds upon a plank, or low bench, placed on the ground, and the end drawn across a table or bench, which is covered with cloth and stuffed. The cloth is stretched out flat upon the surface of the table, and is retained by hooks and weights. Two workmen are now employed who place the lower blades of their shears flat on the surface of the cloth, with the line of the edge in the direction of the length of the piece; one of the shears is laid on the edge or list of the cloth, and the other exactly in the middle of the breadth of the cloth. The bows and stems of the shears project over the edge of the table where the workmen place themselves. Each man guides the shears with his left hand, and makes the cut with his right. To hold the shears a short staff is lashed to the bow of the shears, and secured by a stay to the lower blade; its direction is nearly parallel to the back edge of the upper blade. The workman puts his arm through the bow as far as the elbow-joint, then lays the fore-arm flat against the staff, which he grasps with the hand; and in this way he has a great command of the shears, leaving the right hand at liberty to work the handle which closes them. This is moved backwards and forwards with great rapidity to make cuts or clips on the cloth, and between every cut the lower blade is moved forward on the cloth. The art consists in moving the shears with proper regularity. To assist this weights are laid on the flat of the lower blade, which press it down into the cushion on which the operation is performed. Common cloth is cut wet the first time, then dressed with teasels, dried, and cut three times in a dry state. The most common shearing-frames used in the manufactories are only intended to give the difficult motion used for cropping by the hand.

We copy the specification of a patent granted to Mr. Harmar, of Sheffield, for a machine for raising a shag on all sorts of woollen cloths, and cropping or shearing them; which, together, come under the description of dressing woollen cloths, and also for cropping or shearing of fustians. This was until a late period very generally used in Yorkshire; it is said to have been since simplified. See plate IV. CLOTH, WOOLLEN.

Fig. 1. exhibits a side and end view of shearing cloth from list to list. A is the frame, with its pillars, legs, and rails. B is the cushion or shear-board over which the cloth is extended. C, the cropper's shears in their situation for working, with their bobs or levers. D, the harness or breeches fitted to each end of the riding

blade of C; at the near end is hollowed the bow of C, and at both ends fastened with screws passing through the blade, or else is grooved to admit the blade, and is fastened with wedges. It is composed of two strong pieces of plank, with holes to admit screws through to nut-screws fastened to their upper surface, and square holes through which pass small pillars; other two pieces of plank are frames for wheels turning on pins (as in drawing), situated under the pieces fastened to the riding blade; here the lower ends of screws are rivetted to plates, but so as to turn, which plates are screwed to the wheel-frames; also, in these lower pieces, small pillars are fixed, which, passing through the upper pieces, steady the harness; those screws turned to right or left bring the edges of C to the angle of B, for the work of shearing. E, the inclined planes down which the wheels of D roll when the machine is working. F is the working axle, with its rods or rails; the gudgeons of this axle rest on the cross rails of A; the axle has the inclination of B and E, as in drawing. Its rods, fixed to the sides of it by projecting pieces, are about four inches from its centre, and the thimbles of G ride down them to keep pace with C in its progress. G is the line communicating at the lower end by a thimble with the rods of F, and at the upper end with the bob or lever of C, as in drawing. H is an axle-tree, with its handle, cog-wheel, and stop, fixed by stops, on which it turns, to the pillars of A. I, the lines communicating with the extremities of K at one end, and the other with H. K, levers, turning on their pins, and, by the action of K and I, work against E, to raise C from B, for all necessary purposes. L, pulleys in their frames, to give a proper direction to I, that the turning of H may have the effect before named. M is a crank attached to the lower gudgeon of F; the crank handle has an eye in it, through which a square leg passes, against which works the lower end of a screw, the nut of which is one side of the said eye. This screw, turned to right or left, loosens or fastens the leg in the eye at pleasure. The said leg at the other extremity has a handle where the near end of the catch N is fitted on. Now, as the leg is shifted by means of its eye and screw in that end where the handle is further from the centre of F, N works O with more speed. N is the catch that works O. O is the cog-wheel of N, with its screw pinion on its axle. P is an iron axle, with pulleys near both ends, with a cog-wheel. R is a small sword, fitted into the mortise of the projection on the lower extremity of F, and pinned, and the other end is fitted to the crank handle of S. S is the crank axle and pulley that carries the band which goes to the power that works the machine. The situation for R, as to that end that sits on the crank of S, is directly behind the lower end of F, and under the further extremity of B, where the crank end of S rides on a stop fixed to the further rail of A; the pulley end, where the stop is, rides on X. Now the crank S being put in motion, gives R the necessary vibration, and R works F, which alternately raising or falling its rods or rails by G, C works; and, to effect the progression of C, F being in a working state, M works N, and O works P, and C is carried forwards by T, and to

carry C forwards faster or slower, as necessary. For the due performance of shearing cloth, the handle of the leg of M, where N is fitted on, must be brought nearer to the centre of F for slacking, and more distant from the said centre to increase the speed, as then N will take more or less teeth in O.

Or the progression in this frame may be effected by the method described in the progression of fig. 3, under the letters M, N, O, P. T, the lines for carrying forwards C by P. U is a projection fastened to D, and works against U when C is about to stop. V is a rail and small sword passing through a mortise fixed to one of the legs of A, at nearly one end, and by a working joint, goes up to near the extremity of W. W is a lever, passing through its fulcrum, and pinned to the upper end of X; and near the other end rests on a small notch, sunk in the inside of the upper end of one of the pillars of A, and weighted in the extremity with lead or iron. X is the step of the pulley end of S, and, by a small sword, goes up to W, on the near side of one of the pillars of A, through which X goes, and moves on a pin, and is the step of one end of O; and the further side of the said pillar, where the letter X stands, is the step of the pulley end of S. Now when U or D works against U or V, W is thrown from its notch, and W sinking raises X, and slackens the band on the pulley of S; then the machine stops, and X, raising the step of S on the further side of the pillar of A, on the near side of it sinks the step of O, and the screw-pinion is thrown out of the large cog-wheel of P. Y is a small axle on steps, fastened to D, with its handle and bands going too near the extremity of Z. Z, two small rails, with catches at their extremities, which fall into notches in D to fasten both the shears of C together. Now when the machine stops, by the means already described, the pressure of the handle of Y raises the catches of Z, from their notches in D, and the shears of C are at liberty, and may be driven by the hand to the necessary situation for shifting the cloth, first turning II to the right, to clear them from B. The cloth being shifted, bring the said shears of C to their proper situation, and the catches of Z will fasten them; then turn II to the left, throwing back its catch, and the shears of C are brought to their work; when lift up to its notch the extremity of W, and the band on S is tightened, and the machine works.

Fig. 2 is a side and the two end views of shearing the length-way of the cloth. A, the frame, with its pillars, legs, and rails. B, a circular cushion, or shear-board, formed to the angle of the cropper's shears, and at each end resting on steps fixed to the top rail of A, to be moved round, as occasion shall require. C, the cropper's shears in its harness, or working position. D, the harness, attached to both ends of the ledger blade of the shears C, as particularly described in fig. 1, under the letter D; but this mode of shearing requires that the strong pieces, attached by screws to the ends of C, should be framed together near the back of the said ledger blade, to take the weight of the ends of the shears. When the whole width of a narrow cloth is shorn, the second shear of C is placed behind

that in drawing, and has another, B, for it to work upon, and I, to be worked by. And that part of D attached to the heel of C and letter E, are lengthened as described, fig. 3, under the letter C; so in like manner the shears are situated behind each other in taking the width of a broad cloth. Here it must be noted, as in this mode of shearing the cloth having the progression, the wheels of D are omitted, and pieces of wood, half rounded, supply their place. E is a small frame in its steps, with its arms and lines. The situation of E is seen under letter D, fig. 3; it is attached to the heel part of the harness, as there seen by the drawing. One of the lines of E goes down to the working-rail of F, in the aforesaid, fig. 3; and the other line communicates with the lever or bob of D. F, the roller, with its handle, on which the cloth to be shorn is wound. G, the small rollers, to guide the cloth to B; the middle one which swells riding on it, lighteneth the lists of the cloth as it rides forwards; the swells are moveable, for the purpose of suiting cloths more or less longlisted. H, the rod, cranked on every side, with the pulley for the progression, and that also which carries a band to the working power situated at the upper end of K, near Q. I is the thimble fitted on the crank, with the line going up to near the extremity of the bob working C. K, and axle, with its cog-wheel and stop, as particularly described, fig. 1, under the letters II, I, K, L, and produce a like effect, and must be fixed to this figure the same as in that. L, the cheek to F, fastened by a pin at the near end, and passing under F, being hollowed to it, the further extremity (being carried under C and B) having a weight suspended on it. M, the roller, with a cog-wheel, to which the end of the cloth is attached; and, being tightened by the handle of F, the weight on L keeps it in that tight state as it is carried through the work. N, an iron axletree, carrying a large pulley with one groove, and a five-groove pulley with its steps, that out of sight lies under A on a cross rail. O, an iron axletree, carrying a five-groove pulley and screw pinion on steps, as in drawing. P, bands going from the small pulley of II to the large pulley of N; and from the five-groove pulley of N to the five-groove pulley of O.

Now these five-grooved pulleys gradually descend in their dimensions from fourteen inches to three inches in one, and the other may be the same dimensions, or very considerably smaller; or it may be reduced to a pulley of three inches diameter with one groove. These five-grooved pulleys stand, in respect to each other, in contrary directions. Now when the crank by a band on the pulley on its upper extremity is set to work, the band B, from the other pulley, puts O and P in motion, and carries forward M. That M may have different speed, the band of the five-groove pulleys must be shifted for that purpose to the different grooves, which give them more or less speed. *The Stop-Frame*—Q, the step where rides the upper end of II, which step at one end is tenoned into the pillar of A, and pinned. R is a small sword, at the lower end tenoned into the extremity of Q, and pinned; and at the upper end is mortised, so as to admit the further end of S. S is the lever, tenoned

into the mortise of R, and pinned, and passing through a mortise in the pillar of A. Now to stop the machine, the near extremity of the lever S must be pressed down, and that slackens the band communicating from the acting power to the pulley of H. When set a-going, the said extremity of S must be lifted up, and pinned there. To work this machine, put the cloth to work as directed under letter M; then throw back the stop of G, and the shears are brought to their work; then raise the extremity of S, and the machine works. Fig. 3 shows a second mode of shearing cloth the length way, a side and end view. A is the frame, with its pillars, legs, and side and end rails. B, the inclined planes, as fig. 1, under E, C, the shear boards, over which the cloth is stretched from H to H; every shear has its board, and is placed by the side of each other, so as to take the width of the cloth; and the shears, situated for the like purpose on them, the harness H, and small working frame E, fig. 2, are lengthened accordingly. D, the cropper's shears in its harness, and bob or working lever, with E, fig. 2, in its proper situations, attached by the steps to the harness of D. E, the axle, with the line communicating with the bob at one end, and at the other with one of the axle rods, by a thimble, described under F and G, fig. 1. F, the line and thimble before named.

G, is a small axle, with its lines, levers, pulleys, &c. particularly described under letters, H, I, K, L, fig. 1. H, rollers for the cloth, and their cog-wheels and stops. I, a lever, with its catch and stop to the wheel of H, which is on the other side of the pillar of A, near the middle of it, and falls into the cog-wheel of H, which line communicates with the lower end of the catches on H and L, and passes through small pulleys, fixed under the catches, on the inside of the frame A, that, by the pressure of the upper extremity of the said lever, the catches are raised out of the cogs of their wheels, to give liberty for winding the cloth when shorn on the roller of H, situated near to I. K, a roller to guide the cloth, when wound forwards, that it may keep its situation on the surface of C: it is placed near the axle G, on steps, in the same direction fixed to the pillars of A. L, an axle, with its handles, cog-wheel, and stop, resting on B, with its near stop. This axle has an aperture through the middle of it lengthwise, to admit the cloth through. Now when the cloth is stretched from one of the rollers of H to the other, by turning L to the right, more regular tightness is given to the cloth, and better fits it for the action of shearing. For effecting the progression in shearing and working the shears, M is a small sword, fitted on the handle of the projection of E at one end, and at the other on the crank handle of N. N, a crank, with its pulley with one groove, and a small five-groove pulley. Or this may be reduced to a small one-groove pulley, of about three inches diameter. The larger one-groove pulley carries a band to the power that drives the machine. The situation of this crank is nearly the same as S, fig. 1, and produces the like effect. O is an axle, with a large five-groove pulley and screw pinion. These pulleys of N and O have their bands, and descend in

their dimensions, as particularly described under letter P, fig. 2. P, a roller, with its cog-wheel, on which the bands wind that carry forward D, D, with all the other shears, more or less, fastened together by a rail, at their proper distances from each other (as in drawing), that each may take its proper share of cloth, being situated as described under letter C. Bands from P to D carry forward the shears of D. For stopping this frame, the stop part of fig. 1, under letters U, V, W, X, must be put to it, fixed to the rails and pillars of A. Q is a projection attached to D, and will stop this frame when the parts above directed are fixed to it in the manner directed, fig. 1. R is a line attached to the shears of D, and, passing through a small pulley fixed in the back rail of A, runs through another pulley fixed in a convenient situation over the frame of this said fig. 3, and by pulling its extremity draws back the shears of D when they have cut their board of cloth. For working this machine, the cloth is wound on the upper roller of H, and round a small roller at the upper end of A, and extended down C, and under K, and to the other roller of H, where it is attached; the stop of the upper roller falling into its wheel, the cloth is tightened by the lower roller and the handles of the roller. L, their respective catches falling into the cogs of their wheels, which keep the cloth in a tight state, then throwing back the catch of G, the shears of D are let down to their work, when, by means of R, they are brought to their proper situation on B. Then lift up the lever of the stop-frame into its notch, as directed under letter S, fig. 2, and the machine works. When the machine stops, as before directed, and particularly described, fig. 1, under X, to shift the cloth for cutting another length, press down the near extremity of I of this third figure, and wind the cloth that is cut on H. When, lifting up the said extremity of I, the cloth may be tightened as above described, and the shears of D shifted to continue their work.

Fig. 4, for raising a shag on cloth preparatory to shearing. A, the side and end rails, legs and pillars, with its teasele frames, and cotters. B, the frames, one open and the other shut, which turn on hinges, and, when shut ready for work, are fastened by buttons screwed loosely to C. C is a frame mortised, to fit four sides of B, when shut; and by projections, or sides fixed to its four corners, rides in the groove of a third frame, fixed to the rails of F. D, a third frame in the inner grooves, or two sides of it; C rides this frame, is attached to F, its projection slides through the gutters or flutes of L, when working. E, the double crank, with its large pulley, which by a band goes to the working power. These cranks stand in contrary directions, on the same axle, that the frame may work alternately. F, working rails, fitted on the crank handles, and fastened on by screws. These rails have a working joint near the side of G, and on the further side of G are attached, by screws, to each end of D; and as E works the frames of D, which carry C and B, works round L, and so raise the shag. G, the pulleys, fixed in their frames, over which F rides. H, the board for raising, in its inclined posture, with the cloth passing over it from one

roller of I to the other. I, the rollers, situated before and behind H, and attached to the legs of A, by screws, the gudgeons rising on steps; and at the upper end of H is a small roller, to guide the cloth round the end of H, which swells for both lists of the cloth, after the manner of fig. 2, under the letter G. K, the cheek to the fore roller I, which at one end is attached to one of the legs of A, and near that end lies over the same roller, and hollowed to fit it, and at the other end carries a weight, as in drawing. L, two pieces of plank, situated on both sides H, at the upper termination of M. The inside of the said planks are fluted or guttered to the angles of L, which stands at the foot of A. The small projection at the top of L is a pattern of the slides fixed to the sides of D, which pass through the aforesaid angle when the frames are working, which raise them to and from the cloth. To effect the revolution of the slides that carry C, the top piece of L is fastened to the side of its plank, at or near the upper end, by a screw, on which it moves, and at or near the bottom end it is fastened to its plank, but with the liberty to play.

When D, by its slides, has passed through the gutter, the lower end of the top piece of L falls, and forms a bridge, to carry the slides of I, to the top of the gutter, for the making of another revolution. M are small swords, terminating in L, and fastened with pins, and passing through sockets fixed to the rail of A, and mortised at the lower extremity into N, where they move on pins. N, a strong rail, extending along the side of A, having a joint in it, and turning on pins in a mortise fixed to the pillars of A. O, an axle, with small projections at its ends, in steps, lying on the lower rail of A, extending from one side of the machine to the other. P, small swords, one tenoned into the projection of O, and the other admitting the near extremity of N, through a mortise where it moves upon a pin. Q, an upright leg, fastened at the lower end to the axle of O, near the lower rail of A. Now by turning this leg to right or left, it moves O, and O by its projection raises and lowers the near extremity of N, and N raises and sinks L, which has a like effect on B, C, D; so that, by these mediums, B is brought into contact with H in all necessary degrees. R is a cog-wheel; its situation is on the further extremity of the back roller of I. S, two catches, for carrying forwards R, attached to I at one end in mortises, and moving on pins, and the other working the cogs of C. T, the working leg, fixed to the further pillar of A by a screw, as in drawing. The upper extremity of the said leg goes through a socket, fixed to the further rail of F, near the upper part of it. Now, by the vibration of this extremity of T, in its socket, by E working F, S carries round R, and by varying the pins of S nearer to, or more distant from, the centre of its motion, the said R is carried forwards either faster or slower. For shifting B and C to right and left of H, for the purpose of raising more regularly U, a cog-wheel and stop of the under side, with a handle near the periphery of the said cog-wheel, to act as a crank on the top-side. F, three rails. The rail that crosses the top of H is tenoned into the

extremities of those that form or lie to the right and left of it. W, the steps on which V right with pins to keep the rails of V in their place. X, bands fastened at one end to C, and the other extremity passing through nuts fixed to V, where they are fastened by the end, screws working through the side of their nuts against them. Y, two legs, fastened together at the lower end by a working joint at the upper ends. The further is attached to the near rail of F, and that nearer works upon a pin, a little short of its extremity, with a catch falling into the teeth of W; and, as it works U round, there is another catch on the same side, which prevents the said U from working back. Now F works Y, and Y works U, and U works by its crank V, and X shifts C from right to left by turns in the degree necessary, by tightening and slacking the band X. Z is the near step of E, screwed to a short rail at one end, tenoned into the near pillar at A, near which the step of A is situated. The other extremity of the said rail is fixed under a pin, on a short upright leg, which at the lower is screwed to the inside of the near rail of A, near which the step of A is situated. Now to set this machine to work, or to stop it when working; for the latter, move the said rail from under its pin, and by raising it, the band on E slackens, and the machine stops; and having extended the cloth from the near roller I, on which it is wound, to that behind H, and fixed the handles in B, with its cutters, and buttoned them down, you must then bring the extremity of Z under its said pin, and the machine works.

A perpetual shearing machine is used in the west of England, and is well adapted for narrow cloths. The shears lay crossways on the piece, which is drawn beneath them regularly in the direction of its length without interruption, and hence its name.

A complete rotatory shearing machine, for cropping cloth of any breadth, was invented by Mr. Price, of Gloucestershire, in 1815, and is described with plates in the Repertory of Arts, vol. xxxix. This machine crops the cloth across the breadth, beginning at one end of the piece and continuing regularly to the other. The cloth for this purpose, is conducted through it by the motion of rollers, and is drawn over a bed or support which lies beneath the stationary or fixed blade of the shears or croppers (which answers to what is called the ledger-blade in the common shears), so that the cloth passes between the bed and the stationary blade. The moving blades of the shears are fixed on the circumference of a cylinder situated above the fixed blade, with its axis exactly parallel to it, and capable of revolving by the power of machinery, so that the edges of the moving blades will be carried against and passed over the edge of the fixed blade, in order to cut away all the wool of the cloth which rises above the edge of the fixed blade. Several such moving blades are fixed upon the same cylinder, to act in succession against the fixed blade; and these moving blades are placed obliquely to the axis of the cylinder, or in such a manner as to form portions of spirals; but, as all parts of the cutting edges are equidistant from the axis of the cylinder, it is

manifest that, in the revolution of the cylinder, every part of each spiral edge is brought in succession into contact with the fixed blade, so that in its revolution it crops off all the wool, which by the progressive motion of the cloth over its bed, is raised up against the fixed edge. The edges of the moving blades are placed at such a degree of obliquity to the axis of the cylinder, that at the same instant the end of one ceases to cut against the edge of the fixed blade, the following revolving blade will begin its action at the other end of the cylinder; therefore, by the time that any one of the revolving edges has passed over and made its cut against the whole length of the fixed blade, and is ready to quit it, the succeeding revolving edge is brought into action, and, when this has passed, the next in succession begins, so as to keep up a continued action. The cloth is stretched in width by a contrivance which he calls stretching-bands, to prevent it getting into folds or wrinkles, which would be injured by the shears, or make irregularities in the shearing.

These stretching-bands are endless straps or bands, each of which is extended over two wheels. The bands have sharp pins projecting from them to prick into the lists at the edges of the cloth; and the bands being so situated that one of them lies exactly beneath each list, they will be caused to circulate round their respective wheels by the motion of the cloth. The stretching of the cloth is effected by the position of the wheels on which the bands circulate, the direction of the bands being slightly oblique to the lengthways of the cloth. The endless straps are so fitted into grooves or troughs, that they are firmly retained to move straight forwards in their oblique direction; and the direction of the obliquity is such, that the bands are nearest together at that end where their pins take hold of the lists of the cloth; but as the bands move forwards with the cloth, they recede from each other, and extend the cloth in breadth in consequence of their obliquity, which may be increased or diminished as is found necessary. The actual width between the two bands can also be regulated according to the width of the piece of cloth. It is not usual to crop the lists of the cloth, and indeed, as the lists are usually of thicker substance than the other parts of the cloth, they would bear up the fixed blade too high from the cloth to cut the nap quite close.

The bed or support on which the cloth is cut is so constructed, that it can be adapted in length to the breadth of the piece of cloth between the lists, in order that the cloth only may be supported or borne up to the edge of the fixed blade; whilst the lists, being depressed or borne down below the level of the bed, by thin slips of metal called guards, will escape the action of cropping, and thereby remain with the long wool upon their surfaces. The bed by which the cloth is borne whilst it is cut is only a narrow ridge of metal, over which it passes, so as to be bent with a sudden curvature, and in this way the nap can be cut more close and even than upon a flat bed or soft cushion. The operation of cutting is facilitated by a row of pieces of metal

screwed to a strong bar, to form a straight edge, very similar to the cutting edge of the fixed blade, but thin and elastic. This edge is placed close to the elevated ridge of the bed, and presses the cloth gently down upon the bed, immediately before it comes to the edge of the fixed blade, against which the nap is to be cut off; this elastic edge being placed on one side of the ridge, and the cutting edge of the lower blade on the other side, the cloth is only exposed for a very narrow space just where it comes to the cutting edge. By this means the cloth can with safety be brought nearer to a level with the upper surface of the fixed blade, so as to shear it closer than could otherwise be done without endangering the cloth. The ends of the ridge part of the bed are composed of a number of narrow plates of metal, accurately fitted together, and placed side by side in a mortise made in the end of the solid bed; their upper ends project out of the mortise so as to line with the elevated ridge, and form a continuation of it; but there is a sliding piece in the bottom of the mortise on which they all bear, and the point of it is of a wedge form. By removing this wedge any number of the moveable pieces may be let down, so as to diminish the length of the elevated part of the bed at pleasure, according to the breadth of the cloth. The whole seems well contrived to effect the desired object.

The cloth, having been shorn for the last time, is brushed over and pressed. The former operation is now generally performed by two cylindrical machine brushes, over which a system of rollers passes the piece, brushing both the sides at the same time. Pressing gives it the final smooth coat and polish: preparatory to which it is doubled and laid in even folds, a leaf or sheet of glazed pasteboard being inserted between each fold or plait of the cloth. It is then covered with thin wooden boards or fences in the press, on which are laid iron plates properly heated, and on the whole, by means of a lever turning a screw, the top of the press is brought down with the degree of force judged necessary to give the gloss. A very high finish however is found objectionable, because the slightest shower of rain marks the cloth. Coarser cloths are glossed with a large hot iron in a hollow box, suspended by tackle from the ceiling, and which two men work backwards and forwards over the surface of the cloth.

By stat. 28 Geo. III. c. 38, all the former statutes respecting the exportation of wool and sheep are repealed; and an infinite variety of regulations and restrictions upon the subject is consolidated into that statute. It is given almost at length in 4 Burn's J. title Woollen Manufacturer. The principal prohibitions are, that if any person shall send or receive any sheep on board a ship or vessel, to be carried out of the kingdom, the sheep and vessel are both forfeited; and the person so offending shall forfeit £3 for every sheep, and suffer solitary imprisonment for three months. But wether sheep, by a licence from the collector of the customs, may be taken on board for the use of the ship's company. And every person who shall export out of the kingdom any wool

or woollen articles, slightly made up, so as easily to be reduced to wool again; or any fullers' earth, or tobacco-pipe clay; and every carrier, ship-owner, commander, mariner, or other person, who shall knowingly assist in exporting or in attempting to export these articles, shall forfeit 3s. for every pound weight, or the sum of £50 in the whole, at the election of the prosecutor, and shall also suffer solitary imprisonment for three months. But wool may be carried coastwise upon being duly entered, and security being given according to the direction of the statute, to the officer of the port from whence the same shall be conveyed. And the owners of sheep, which are shorn within five miles of the sea, and ten miles in Kent and Sussex, cannot remove the wool, without giving notice to the officer of the nearest port as directed by the statute. Much contest having arisen as to the

policy, in the present times, of several acts heretofore made for the regulation of the woollen manufactures; these acts were by 43 Geo. III. c. 136 (a temporary act continued by several subsequent acts), suspended with a view to the framing of a new law on the subject. At length by stat. 49 Geo. III. c. 109. several acts, and parts of acts (nearly forty in number), on this subject from the 2 of Edw. III. to 5 Geo. III. are repealed: and persons having served apprenticeship to any branch of the woollen manufactures, and their wives and families, are allowed to set up and exercise that trade, or any other, in any part of Great Britain, notwithstanding the restrictions in stat. 5 Eliz. c. 4. There are other miscellaneous woollen goods of considerable importance; and we propose, in a history of the WOOLLEN MANUFACTURE of Great Britain, to give a summary of those of each of its branches.

CLOTH, INCOMBUSTIBLE. See ASBESTOS.

CLOTH, LINEN. See LINEN.

CLOTIO, from κλωθειν, to spin, the first of the three Paræ, or Fates, daughter of Jupiter and Themis. She was supposed to preside over the time of birth. She held the distaff in her hand and spun the thread of life. She was represented wearing a crown with seven stars, and covered with a variegated robe.

CLOTPOLL, *n. s.* from clot and poll. Thick-scul; blockhead.

What says the fellow, there? call the *clotpoll* back.
Shakspeare.

Head, in scorn.

I have sent Cloten's *clotpoll* down the stream,
In embassy to his mother. *Shakspeare. Cymbeline.*

CLOUD, *n. s., v. a. & v. n.* } The derivation is
CLO'DILY, *adv.* } not known. Min-
CLO'UDINESS, *n. s.* } shew derives it from
CLO'UDLESS, *adj.* } *claudo* to shut;
CLO'UDY, *adj.* } Somner from *clod*;

Casaubon from ἀχλὺς, darkness; Skinner from *kludde*, Dutch, a spot. The embodied vapors of the atmosphere; or obscurity; a stain; a multitude of people; an host; Goth. *lyd*; Sax. *leod*; Teut. *liut*; Sax. *ploth*; a crowd, a troop; anything that spreads, variegates, obscures; fills the air with gloom, the mind with confusion, the heart with sadness. It sometimes is applied to a den in the mountains; a rock, a cliff. Goth. *klett*; Sax. *clud*, *pleoth*, *pleoth*.

The 'derknesse of deeth,' ben the sinnes that the wretched man hath don, which that distrouben him to see the face of God; right as a derke *cloud*, betwene us and the sonne. *Chaucer. The Persones Tale.*

O sterc of steres, with thy stremes clere,
Sterc of the se, to shippman light and gide!

O lustie, living, moste plescaunt to appere,
Whose bright-bemes the *cloudes* maie not hide!

O Waie of life to hem that go or ride;
Haven after tempest, surest up to rive
On me have merrie for thy joyes five. *Id.*

Their captaine there they cruelly found kild,
And in his armes the dreary dying mayd,

Like a sweet angell twixt two *clouds* uphild,
Her lovely light was dimmed and decayed
With *cloud* of death upon her eyes displayed;
Yet did the *cloud* make even that dimmed light
Secme much more lovely in that darknesse laid,
And twixt the twinkling of her eye-lids bright,
To sparke out little beames, like starrs in foggie
night. *Id.*

Some had rather have good discipline delivered
plainly, by way of precepts, than *cloudily* wrapped
in allegories. *Id.*

So my storm-beaten heart likewise is cheered
With that sun-shine, when *cloudy* looks are cleared.
Spenser.

Witness my son, now in the shade of death,
Whose bright outshining beams thy *cloudy* wrath
Hath in eternal darkness folded up. *Shakspeare.*

Now are the *clouds*, that lowered upon our house,
In the deep bosom of the ocean buried. *Id. Richard III.*

You have such a February face,
So full of frost, of storm, and *cloudiness*. *Id.*

For shedding round about his sparkling light,
He clears their dusky shades, and *cloudy* night,
Producing lik' himself their shapes all shining bright.
Fletcher's Purple Island.

Be not disheartened then, nor *cloud* those looks,
That want to be more cheerful and serene. *Milton.*

The' poets may of inspiration boast,
Their rage, ill governed, in the *clouds* is lost. *Waller.*

Clouds are the greatest and most considerable of all the meteors, as furnishing water and plenty to the earth. They consist of very small drops of water, and are elevated a good distance above the surface of the earth; for a *cloud* is nothing but a mist flying high in the air, as a mist is nothing but a *cloud* here below. *Locke.*

As a mist is a multitude of small but solid globules, which therefore descend; so a vapour, and therefore a watery *cloud*, is nothing else but a congeries of very small and concave globules, which therefore ascend to that height in which they are of equal weight with the air, where they remain suspended, till, by some motion in the air, being broken, they descend in solid drops; either small, as in a mist; or bigger, when many of them run together, as in rain. *Green's Cosmologia.*

I saw a *cloudy* Hungarian diamond made clearer by lying in a cold liquor; wherein, he affirmed, that upon keeping it longer, the stone would lose more of its *cloudiness*. *Boyle.*

If men would not exhale vapours to *cloud* and darken the clearest truths, no man could miss his way to heaven for want of light. *Decay of Piety.*

How can I see the brave and young
Fall in the *cloud* of war, and fall unsung? *Addison.*

The objection comes to no more than this, that, amongst a *cloud* of witnesses, there was one of no very good reputation. *Atterbury.*

This Partridge soon shall view in *cloudless* skies,
When next he looks thro' Galilæo's eyes. *Pope.*

The handle smooth and plain,
Made of the *clouded* olive's easy grain. *Id.*

The purple *clouds* their amber linings show,
And edged with flame rolls every wave below. *Gay.*

If you content yourself frequently with words instead of ideas, or with *cloudy* and confused notions of things, how impenetrable will that darkness be!
Watts on the Mind.

Now beamed the evening star,
And from embattled *clouds* emerging slow,
Cynthia came riding on her silver car,
And hoary mountain cliffs shone faintly from afar. *Beattie.*

The gusts of appetite, the *clouds* of care,
The storms of disappointments all o'ercast,

Henceforth no earthly hope with Heaven shall share
This heart, where peace serenely shines at last. *Id.*

Lone as a solitary *cloud*,
A single *cloud* on a sunny day,
While all the rest of heaven is clear,
A frown upon the atmosphere,
That hath no business to appear
When skies are blue, and earth is gay.

Byron. Prisoner of Chillon.

CLOUDS. That clouds are formed from the aqueous vapors, which before were so closely united with the atmosphere as to be invisible, is universally allowed: but it is no easy matter to account for the long continuance of some very opaque clouds without dissolving; or to give a reason why the vapors, when they have once begun to condense, do not continue to do so till they at last fall to the ground in the form of rain or snow, &c. A general cause of the formation of clouds has been often suggested; namely, a separation of the latent heat from the water of which the vapor is composed. The consequence of this separation, as is proved by Dr. Black, must be the condensation of that vapor, in some degree at least. In such case, it will first appear as a smoke, mist, or fog; which, if interposed betwixt the sun and earth, will form a cloud; and, the same causes continuing to act, the cloud will produce rain or snow. But though the separation of this latent heat, in a certain degree, is the immediate cause of the formation of clouds, the remote cause, or the changes produced in the atmosphere, whereby such a preparation may be induced, are much more difficult to be discovered. Common observation shows that vapor is most powerfully condensed by cold substances, such as metals, water, &c. But cold alone cannot in all cases cause the condensation of the atmospherical vapors, otherwise the nights would be always foggy or cloudy, owing to the vapors

of the day being condensed by the superior coldness of the night. Great rains will happen in very warm weather, when the union of the vapors with the atmosphere ought rather to be promoted than dissolved, if cold was the only agent in their condensation. The serenity of the atmosphere, also, in the most severe frosts, abundantly shows that some other cause besides mere heat or cold is concerned in the formation of clouds, and condensation of the atmospherical vapors.

The electric fluid is now generally admitted as one agent in all these great operations of nature. It has been even assigned by Beccaria as the cause of the formation of all clouds whatsoever, whether of thunder, rain, hail, or snow. But though it is certain that all clouds, or even fogs and rain, are electrified in some degree, it still remains a question, whether any clouds are formed in consequence of the vapor of which they are composed being first electrified, or whether they become electrified in consequence of its being first separated from the atmosphere, and in some measure condensed. Electricity is known to be in many cases a promoter of evaporation; but no experiments have yet been brought to prove that electrified air parts with its moisture more readily than such as is not electrified; so that, till the properties of electrified air are farther investigated, it is difficult to lay down any rational theory of the formation of clouds upon this principle. Instances of the descent of very highly electrified clouds have not been uncommon. Brydone, in his Tour through Malta, mentions a remarkable one which appeared on the 29th of October, 1757. About three quarters of an hour after midnight, there was seen to the south-west of the city of Melita, a great black cloud, which, as it approached, changed its color, till at last it became like a flame of fire mixed with black smoke. A dreadful noise was heard on its approach, which alarmed the whole city. It passed over the port, and came first on an English ship, which in an instant was torn in pieces, and nothing left but the hulk; part of the masts, sails, and cordage, were carried to a considerable distance along with the cloud. The small boats and felloques that fell in its way were all broken to pieces and sunk. The noise increased and became more frightful. A sentinel, terrified at its approach, ran into his box; but both he and it were lifted up and carried into the sea, where he perished. It then traversed a considerable part of the city, and laid in ruins almost every thing that stood in its way. Several houses were laid level with the ground, and it did not leave one steeple in its passage. The bells of some of them, together with the spires, were carried to a considerable distance; the roofs of the churches demolished and beat down, &c. It went on at the north-east point of the city, and, demolishing the light-house, is said to have mounted up into the air with a frightful noise; and passed over the sea to Sicily, where it tore up some trees, and did other damage; but nothing considerable, as its fury had been mostly spent at Malta. The number of killed and wounded amounted to nearly 200; and the loss of shipping, &c., was very considerable.

The effects of thunder-storms, and the vast quantity of electricity collected in the clouds which produce these storms, are so well known, that it is superfluous to mention them. It appears, however, that even these clouds are not so highly electrified as to produce their fatal effects on those who are immersed in them. It is only the discharge of part of their electricity upon such bodies as are either not electrified at all, or not so highly electrified as the cloud that produces the mischief. Professor Saussure, and young Mr. Jalabert, when travelling over one of the high Alps, supply a singular instance of being caught among clouds of this kind; to their astonishment they found their bodies so full of electrical fire, that spontaneous flashes darted from their fingers with a crackling noise, and they had the same kind of sensation as when strongly electrified by art.

The height of clouds in general is not great; the summits of very high mountains being commonly quite free from them. But those which are most electrified descend lowest, their height being often not above 700 or 800 yards above the ground; nay, sometimes thunder clouds appear actually to touch the ground with one of their edges. But the generality of clouds are suspended at the height of a mile, or little more, above the earth. Some, however, have imagined them to arise to a most incredible and extravagant height.

The motions of the clouds are not always directed by the wind; they seem to move very slowly when we have considerable gales, and often to be absolutely stationary for a time. The reason of this probably is, that they are impelled by opposite streams of air of equal strength; by which means their velocity is retarded. In such cases both the aerial currents seem to ascend to a very considerable height; for Messrs. Charles and Roberts, when endeavouring to avoid a thunder cloud in one of their aerial voyages, could find no alteration in the course of the current, though they ascended to the height of 4000 feet from the surface of the earth. In some cases the motions of the clouds evidently depend on their electricity, independent of any current of air. Professor Leslie, in his very able article on Meteorology, in the Supplement to the Encyclopædia Britannica, contends that Dr. James Hutton first suggested the true theory of clouds, in his paper upon the subject of Rain, in the Transactions of the Edinburgh Royal Society, 1787. He thus endeavours to define and complete it:—

‘Air, in cooling, becomes ready to part with its moisture. But how is it cooled in the free atmosphere, unless by the contact or commixture of a colder portion of the same fluid? Now, the portion of the air which is chilled, must in an equal degree warm the other. If, in consequence of this mutual change of condition, the former be disposed to resign its moisture, the latter is more inclined to retain it; and, consequently, if such opposite effects were balanced, there could, on the whole, be no precipitation of humidity whatever. The separation of moisture, on the mixing of two masses of damp air at different temperatures, would therefore prove, that the dissolving power of air suffers more diminution from losing

part of the combined heat, than it acquires augmentation from gaining an equal measure of it; and, consequently, this power must, under equal accessions of heat, increase more slowly at first than it does afterwards, thus advancing always with accumulated celerity.

‘The quantity of moisture which air can hold thus increases in a much faster ratio than its temperature. This great principle in the economy of nature was traced by Dr. Hutton from indirect experience. It is the simplest of the accelerating kind, and perfectly agrees with the law of solution, which the hygrometer has established. Suppose equal bulks of air in a state of saturation, and at the different temperatures of 15 and 45 centesimal degrees, were intermixed, the compound arising from such union will evidently have the mean temperature of 30°. But since, at these temperatures, the one portion held 200 parts of humidity, and the other 800, the aggregate must contain 1000 parts, or either half of it 500; at the mean or resulting temperature, however, this portion could only suspend 400 parts of humidity, and consequently, the difference, or 100 parts, amounting to the 200th part of the whole weight of air, must be precipitated from the compound mass. As another illustration, let air of 15° be mixed with air at the temperature of 35°, in three different proportions, all at the point of saturation; one part being combined with three parts, two with two, and three with one. The temperatures arising from the commixture would be 20°, 25°, and 30°; the corresponding parts of moisture precipitated from the mass being derived from the intermediate proportions of 200 and 504, are 352—317·5, or 34·5, 276—252 or 24, 352—317·5 or 34·5, and 428—400 or 28.

‘In these examples we have assumed the portions of differently heated air to be quite charged with moisture before mixing; but it is only required that they should approach to the point of humidity. The effect, however, of simple commixture would, in most cases, be very small. To explain the actual phenomena, we must have recourse to the mutual operation of a chill and of a warm current, driving swiftly in opposite directions, and continually mixing and changing their continuous surfaces. By this rapidity, a larger volume of the fluid is brought into contact in a given time. Suppose, for instance, the one current to have a temperature of 50°, and the other that of 70°, by Fahrenheit’s scale; the blending surfaces will therefore assume the mean temperature of 60°. Consequently, the two streams throw together 200 and 234·2 parts of moisture, making 567·1 parts for the compound, which, at its actual temperature, can hold only 258·6 parts; the difference, or 308·5 parts, forms the measure of precipitation, corresponding to the 2325th of the whole weight of the commixed air. It would thus require a column of air thirty miles in length to furnish, over a given spot, and in the space of an hour, a deposit of moisture equal to the height of an inch. If the sum of the opposite velocities amounted to sixty miles an hour, and the intermingling influence extended but to a quarter of an inch at the grazing surfaces, there would still, on this supposition,

be produced in the same time a fall of rain reaching to half an inch in altitude.

These quantities come within the limits of probability, and agree sufficiently with experience and observation. But in the higher temperatures, though the difference of the heat between the opposite strata of air should remain the same, the measure of aqueous precipitation is greatly increased. Thus, while the mixing of equal masses of air, at the temperatures of 40° and 60°, is only 6·6, that from a like mixture at 80° and 100° amounts to 19°. This result is entirely conformable to observation; for showers are most copious during hot weather, and in the tropical climates. The quantity of moisture precipitated from the atmosphere thus depends on a variety of circumstances: on the previous dampness of the combined portions of the fluid; their difference of heat; the elevation of their mean temperature; and the extent of the combination which takes place. When this deposition is slow, the very minute aqueous globules remain suspended, and form clouds; but if it be rapid and copious, those particles conglomerate, and produce, according to the state of the medium with regard to heat, rain, hail, or snow.

But Mr. Luke Howard of London has furnished the most complete classification and exposition of these phenomena, in his *Nomenclature and Observations on Clouds*, published in the 16th and 17th vols. *Philosophical Magazine*.

The simple modifications are thus defined: 1. *Cirrus*. Parallel, flexuous, or diverging fibres, extensible in any or in all directions. 2. *Cumulus*. Convex or conical heaps, increasing upwards from a horizontal base. 3. *Stratus*. A widely extended, continuous, horizontal sheet, increasing from below.

The intermediate modifications which require to be noticed are, 4. *Cirro-cumulus*. Small well-defined roundish masses, in close horizontal arrangement. 5. *Cirro-stratus*. Horizontal, or slightly inclined masses, attenuated towards a part or the whole of their circumference, bent downward or undulated, separate or in groups, consisting of small clouds having these characters.

The compound modifications are, 6. *Cumulo-stratus*. The cirro-stratus, blended with the cumulus, and either appearing intermixed with the heaps of the latter, or superadding a widespread structure to its base.

7. *Cumulo-cirro-stratus, vel nimbus*, is the rain cloud. A cloud or system of clouds from which rain is falling. It is a horizontal sheet, above which the cirrus spreads, while the cumulus enters it laterally and from beneath.

The cirrus appears, according to this author, to have the least density, the greatest elevation, the greatest variety of extent and direction, and to appear earliest in serene weather, being indicated by a few threads pencilled on the sky. Before storms they appear lower and denser, and usually in the quarter opposite to that from which the storm arises. Steady high winds are also preceded and attended by cirrus streaks, running quite across the sky in the direction they blow in.

The cumulus has the densest structure, is formed in the lower atmosphere, and moves

along with the current next the earth. A small irregular spot first appears, and is, as it were, the nucleus on which they increase. The lower surface continues irregularly plane, while the upper rises into conical or hemispherical heaps; which may afterwards continue long nearly of the same bulk, or rapidly rise into mountains. They will begin, in fair weather, to form some hours after sunrise, arrive at their maximum in the hottest part of the afternoon, then go on diminishing and totally disperse about sunset. Previous to rain, the cumulus increases rapidly, appears lower in the atmosphere, and with its surface full of loose fleeces or protuberances. The formation of large cumuli to leeward in a strong wind, indicates the approach of a calm with rain. When they do not disappear or subside about sunset, but continue to rise, thunder is to be expected in the night. The *stratus* has a mean degree of density, and is the lowest of clouds, its inferior surface commonly resting on the earth or water. This is properly the cloud of night appearing about sunset. It comprehends all those creeping mists, which in calm weather ascend in spreading sheets, like an inundation of water, from the bottom of valleys, and the surfaces of lakes and rivers. On the return of the sun, the level surface of this cloud begins to put on the appearance of cumulus, the whole at the same time separating from the ground. The continuity is next destroyed, and the cloud ascends and evaporates, or passes off with the appearance of the nascent cumulus. This has long been experienced as a prognostic of fair weather.

The cirrus having continued for some time increasing or stationary, usually passes either to the cirro-cumulus or the cirro-stratus, at the same time descending to a lower station in the atmosphere. This modification forms a very beautiful sky; is frequent in summer, an attendant on warm and dry weather. The cirro-stratus, when seen in the distance, frequently gives the idea of shoals of fish. It precedes wind and rain; is seen in the intervals of storms; and sometimes alternates with the cirro-cumulus in the same cloud, when the different evolutions form a curious spectacle. A judgment may be formed of the weather likely to ensue by observing which modification prevails at last. The solar and lunar *haloes*, as well as the parheliac and paraselenic (mock sun and mock moon), prognostics of foul weather, are occasioned by this cloud. The cumulo-stratus precedes, and the nimbus accompanies rain. Mr. Howard gives a view of the origin of clouds, which will be found worth consulting. The uses of the clouds are obvious; from them proceeds the rain which refreshes the earth, without which according to the present system of nature, the whole of its surface would be a mere desert. They are likewise of great use as a screen, interposed between the earth and the scorching rays of the sun, which are often so powerful as to destroy the grass and other tender vegetables. In the more secret operations of nature also, where the electrical fluid is concerned, the clouds bear a principal share; and serve as a medium for conveying that fluid from the atmosphere into the earth, and from the earth into the atmosphere.

CLOUDS.

1 Cirrus or Curlcloud 2 Cirrocumulus or Sandercloud 3 4 5 Cirrostratus or Wanecloud 6 Cumulostratus or Beam cloud 7 Cumulus or Stakencloud 8 Nimbus or Raincloud 9 Stratum or Fallcloud

CLOUD (St.), a town and palace of France, in the province of the Isle of France, situated on the Seine. The palace, though not the largest, is one of the most pleasantly situated, and beautiful, of any in the neighbourhood of Paris. It contains several beautiful specimens of the fine arts, has a park, gardens, and cascades. The great cascade is 108 feet in width, and the same in height. The terrace affords an extensive view of Paris. Henry III. was assassinated here in 1580, and here Napoleon principally resided. It has a fine manufacture of porcelain; five miles west of Paris.

CLOUDBERRY, *n. s.* from cloud and berry, *chamæmorus*. The name of a plant, called also knoberry.

CLOUDCAPT, *adj.* from cloud and cap. Topped with clouds; touching the clouds.

The *cloudcapt* towers, the gorgeous palaces,
The solemn temples, the great globe itself,
Yea, all which it inherits, shall dissolve. *Shakspeare.*

CLOUDCOMPELLING, *adj.* A word formed in imitation of *νεφέληγατηγος*, ill understood. An epithet of Jupiter, by whom clouds were supposed to be collected.

Health to both kings, attended with a roar
Of cannons, echo'd from the affrighted shore;
With loud resemblance of his thunder prove
Bacchus the seed of *cloudcompelling* Jove. *Waller.*

Supplicating move
Thy just complaint to *cloudcompelling* Jove. *Dryden.*

CLOVE, *n. s.* the preterite of cleave. See *To CLEAVE*.

Gyon's angry blade so fierce did play
On the other's helmet, which as Titan shone,
That quite it *cleave* his plumed crest in tway. *Færic Queen.*

CLOVE, *n. s.* Fr. *clou*, a nail, from the similitude of a clove to a nail. A valuable spice brought from Ternate in the East Indies. It is the fruit or seed of a very large tree.

Clove seems to be the rudiment or beginning of a fruit growing upon *clove-trees*.

Browne's Vulgar Errors.

Some of the parts into which garlick separates,
when the outer skin is torn off. In this sense it is derived from clove, the preterite of cleave.

'Tis mortal sin an onion to devour;
Each *clove* of garlick is a sacred power. *Tate's Juvenal.*

CLOVE JULY-FLOWER. See *DIANTHUS*.

CLOVE-TREE. See *CARYOPHYLLUS*.

CLOVEN, *part. pret.* from cleave. See *To CLEAVE*.

There is Aufidius, list you what work he makes
Among your *cloven* army. *Shakspeare.*

Now heaped high
The *cloven* oaks and lofty pines do lie. *Waller.*

A chap-fallen beaver, loosely hanging by
The *cloven* helm, and arch of victory. *Dryden.*

CLOVEN-FOOTED, *adj.* } Cloven and foot, or
CLOVEN-HOOFED. } hoof. Having the foot divided into two parts: not a round hoof; bisulcous.

There are the bisulcous or *cloven-hoofed*; as camels and beavers. *Browne's Vulgar Errors.*

The *cloven-footed* fiend is banished from us. *Dryden.*

Great variety of water fowl, both whole and *cloven-footed*, frequent the waters. *Ray on the Creation.*

Whether the serpent at the fall
Had *cloven* feet, or none at all. *Hudibras.*

And for his aspect, look upon the fountain
And then on me, and judge which of us twain
Look likest what the boors believe to be
Their *cloven-footed* terror.

For n. Deformed Transformed.

CLOVER, *n. s.* } Dutch *kliver*; Sax.
CLOVER-GRASS, *n. s.* } *clafar*; from its cleft
CLOVERED, *adj.* } leaves, a species of trefoil: a rich provision for cattle; and so great a luxury, that when an individual has all the comforts of life in abundance, he is said to live in clover.

The even mead, that erst brought sweetly forth
The freckled cowslip, burnet, and green *clover*. *Shakpeare.*

Nature shall provide
Green grass and fattening *clover* for their fare. *Dryden.*

Clover improves land, by the great quantity of earth it maintains. *Mortimer's Husbandry.*

My Blouzelinda is the blithest lass,
Than primrose sweeter, or the *clover* grass. *Gay.*

Flocks thick nibbling thro' the *clovered* vale. *Thomson.*

Well, Laureat was the night in *clover* spent. *Ogle.*

CLOVER, in botany. See *TRIFOLIUM*, and *AGRICULTURE*.

CLOUGH, *n. s.* Sax. clough. The cleft of a hill; a vale between cliffs.

CLOUGH, *n. s.* in commerce, an allowance of two pounds in every hundred weight for the turn of the scale, that the commodity may hold out weight when sold by retail.

CLOVIO (George Julius), a celebrated historical and portrait painter, was born at Selavonia in 1493. At eighteen years of age he went to Rome, where he spent three years, devoting himself entirely to painting in miniature. His knowledge of coloring was established by the instructions of Julius Romano, and his taste of composition and design was founded on the works of Michael Angelo. He thus acquired so great a degree of excellence in portrait, as well as in historical painting, that in the former he was considered equal to Titian, and in the latter not inferior to Buonaroti. He died in 1578. His works are exceedingly valuable, and are still numbered among the curiosities of Rome.

CLOVIS I. the real founder of the French monarchy, was born in 467, and succeeded his father Childeric in 481. His first exploit was the defeat of Syagrius, the Roman governor of Gaul, after which he took Soissons, and made it his capital. His wife Clotilda prepared him for the reception of Christianity, which, however, he did not embrace till after a victory obtained over the Germans, which he attributed to the effect of his prayer to the God of the Christians before the battle. He was soon after publicly baptised with 3000 of his subjects, by St. Reni, archbishop of Rheims, and his fitness for the ceremony may be judged of from his declaration on hearing of the sufferings of Christ. 'Had I been there,' said he, 'with my valiant Goths, how I would have avenged him!' He was a warlike prince, and conquered the several provinces of

Gaul, possessed before his time by the Romans, Germans, and Goths. These he united to the then scanty dominions of France, removed the seat of government from Soissons to Paris, and made this the capital of his new kingdom. Under the pretext of zeal for the conversion of the Visigoths in Gaul, he invaded their territory, and killed Alaric their prince with his own hand. The Visigoths were afterwards assisted by Theodoric, king of Italy, and Clovis was obliged to retreat with great loss, from the siege of Arles. These tribes were finally allowed by treaty to retain the country of Septimania, comprising the sea-coast from the Rhone to the Pyrenees, while the country thence to the Loire was given up to Clovis. He was soon honored by the emperor Anastasius with the Roman titles of patrician, consul, and Augustus. In his advanced age, he founded several churches and monasteries, in expiation of his sins, and was very zealous for the Catholic faith. After being acknowledged king of all the Franks in Gaul, he died at Paris in 511, in the forty-fifth year of his age, after a reign of thirty years. He left four sons, for whom he founded four kingdoms. See FRANCE, HISTORY OF.

CLOUT, *n. s.* & *v. a.* } Sax. *clut*; Swed.
CLOUTED, *part. adj.* } *klut*. A fragment or
CLOUTERLY, *adj.* } small piece of cloth;
a patch; a mean fellow; a clown; a booby;
a cuff; a blow with the hand. To clout is to
patch, to mend coarsely; to cover with a cloth;
to join awkwardly, or coarsely together.
Clouted is sometimes corruptly used for clotted.
Clouterly is louterly, that is clumsy, awkward.
Anciently the mark of white cloth, at which
archers shot was called a clout.

And when she of this bill hath taken hede,
She sent it all to cloutes. *Chaucer. Canterbury Tales.*

Many sentences of one meaning clouted up together.
Ascham.

His garment nought but many ragged clouts,
With thorns together pinned, and patched was.
Spenser.

A clout upon that head,
Where late the diadem stood. *Shakespeare.*

Milk some unhappy ewe,
Whose clouted leg her hurt doth shew. *Spenser.*

He drew a good bow; he shot a fine shoot; he
would have clapt in the clout at twelve score.
Shakespeare.

I thought he slept and put
My clouted brogues from off my feet, whose rudeness
Answered my steps too loud. *Id.*

His clothes all patched with more than honest thrift,
And clouted shoes were nailed for fear of wasting:

Fasting he praised, but sparing was his drift,
And, when he eats, his food is worse than fasting.
Fletcher's Purple Island.

The dull swain
Treads on it daily with his clouted shoon. *Milton.*
The single wheel plough is a very clouterly sort.
Mortimer's Hiwandy.

I've seen her skim the clouted cream,
And press from spongy curds the milky stream. *Gay.*

CLOWES (William), an eminent surgeon in
the English navy, in the reign of queen Elizabeth,
settled about 1573 in London, and became
surgeon to Christ's and St. Bartholomew's Hos-

pitals. He went to the Netherlands in 1586, to
superintend the care of the wounded in the army
of the earl of Leicester. He died some time
before 1631; and was the author of treatises On
Syphilis, and On the Cure of Wounds.

CLOWN, *n. s.* } From Lat. *colonus*,
CLOW'NERY, *n. s.* } according to Junius; or
CLOW'NISH, *adj.* } *loon*, a hired servant; a
CLOW'SHLY, *adv.* } peasant; an ill bred
CLOW'NISHNESS, *n. s.* } man; the cognomen for
all that is churlish, rude, uncivil, and brutal.

He came with all his clowns, horsed upon cart-jades.
Sidney.

But with his clownish hands their tender wings
He brusheth oft. *Spenser's Faerie Queene.*

What if we essayed to steal
The clownish fool out of your father's court?
Shakespeare.

Height with a certain grace does bend,
But low things clownishly ascend. *Marvell.*

The fool's conceit had both clownery and ill-nature.
L'Estrange.

The clowns, a boisterous, rude, ungoverned crew,
With furious haste to the loud summons flew.
Dryden.

Young Silvia beats her breast, and cries aloud,
For succour from the clownish neighbourhood. *Id.*

Even his Doric dialect has an incomparable sweet-
ness in his clownishness. *Id.*

If the boy should not make legs very gracefully, a
dancing master will cure that defect, and wipe off that
plainness which the à-la-mode people call clownishness.
Locke.

With a grave look, in this odd equipage,
The clownish mimic traverses the stage. *Prior.*

In youth a coxcomb, and in age a clown. *Spectator.*

A country squire, represented with no other vice
but that of being a clown, and having the provincial
accent. *Swift.*

Touched by thy rod, from Power's majestic brow,
Drops the gay plume, he pines a lowly clown,

And on the cold earth stretched the son of Woe,
Quaffs Pleasure's draughts, and wears a fancied crown.
Beattie.

CLOWN'S MUSTARD, *n. s.* An herb.

CLOY, *v. a.* } Fr. *clouer*, from clou;
CLOY'LESS, *adj.* } Lat. *clavis*. To stop up, to

CLOYMENT, *n. s.* } fill at once, to spike guns,
to drive a nail into the touch-hole. Cloyment is
repletion: cloyless is that of which too much
cannot be had; that which cannot cause satiety.

The length of those speeches had not cloyed Py-
rocles, though he were very impatient of long delib-
erations. *Sidney.*

The very creed of Athanasius, and that sacred hymn
of glory, are reckoned as superfluities, which we must
in any case pare away, lest we cloy God with too
much service. *Hooker.*

Who can cloy the hungry edge of appetite
By bare imagination of a feast? *Shakespeare.*

Alas! their love may be called appetite:
No motion of the liver, but the palate,
That suffers surfeit, cloyment, and revolt. *Id.*

Epicurean cooks
Sharpen with cloyless sauce his appetite. *Id.*

Wealth which all other's avarice might cloy;
But yet in them caused as much fear as joy. *Marvell.*

Settle, cloyed with custard and with praise,
Is gathered to the dull of ancient days. *Pope.*

He envied not, he never thought of kings,
Nor from those appetites sustained annoy,
That chance may frustrate, or indulgence cloy.

Beattie.

CLOYNE, a town of Ireland, in Cork, Munster, one mile from the sea-coast. A church was built in it, and a bishopric erected by St. Colman, in the end of the sixteenth century; and in 707 an abbey was founded. In 1430 the bishopric was united to that of Cork; and the union continued till the 11th of November 1638; since which time this see has been governed by its own prelates. The cathedral is a decent Gothic building. Cloyne lies ten miles west of Youg-hall, and 125 south-west of Dublin.

CLUB, *n. s.* } Swed. *klubba*; Dan. *klub*; Teut. *klopfè*; Wel. *cluppa*; Lat. *clava*. A heavy stick, a mace, a staff intended for offence. Club-headed is a thick, clumsy, oaken sort of head, like the ponderous end of a club. Club-law is the law of force, a suit of cards marked with a club, or rather with a clover leaf, bears this name.

When I bete my knaves,
She bringeth me the great *clubbed* staves.
And crieth; see the dogges everich on,
And brek hem both bak and evey bon.

Chaucer's Canterbury Tales.

Next Hercules his like ensample shewed,
Who all the west with equal conquest wonne,
And monstrous tyrants with his *club* subdewed.
The *club* of justice dread, with kingly power endewed.

Spenser.

He strove his combre *club* to quit
Out of the earth. *Id. Fœnic Queene.*

They are in the very wrath of love, and they
will together, *clubs* cannot part them. *Shakspeare.*

As he pulled off his helmet, a butcher slew him
with the stroke of a *club*. *Hayward.*

Small *club-headed* anterinæ. *Derham.*

Armed with a knotty *club* another came. *Dryden.*

The enemies of our happy establishment seem
to have recourse to the laudable method of *clubbæ*,
when they find all other means for enforcing the ab-
surdity of their own opinions to be ineffectual.

Addison's Freeholder.

The *clubs* black tyrant first her victim died,
Spite of his haughty mein and barbarous pride.

Pope.

CLUB, *n. s., v. n. & v. a.* } Goth. *kluff*; Swed. *klub*; Belgic *kloof*;

CLUB-ROOM, *n. s.* } Teut. *klub*; Teut. *clurben, kloeben*. A portion or apportioning, a division, a society paying equally. An assembly, meeting under certain conditions; a voluntary association generally for purposes of conviviality; sometimes for mutual benefit, by contributing each to the common stock; concurrence, contribution, joint charge; to contribute separate powers to one end; to pay to a common reckoning. Club-room needs no explanation.

A fuddling couple sold ale: their humour was to
drink drunk, upon their own liquor: they laid down
their *club*, and this they called forcing a trade.

L'Estrange.

What right has any man to meet in factious *clubs*
to vilify the government. *Dryden. Medul. Ded.*

Till grosser atoms, tumbling in the stream
Of fancy, madly met, and *clubbed* into a dream.

Dryden.

He's bound to vouch them for his own,
Though' got by' implicate generation,
And general *club* of all the nation. *Hudibras.*

The owl, the raven, and the bat,
Clubbed for a feather to his hat. *Swift.*

I shall reserve for another time the history of such
club or *clubs*, of which I am now a talkative, but un-
worthy member. *Spectator.*

These ladies resolved to give the pictures of their
deceased husbands to the *club-room*. *Addison's Spectator.*

Plumbs and directors, Shylock and his wife,
Will *club* their testers now to take your life. *Pope.*

CLUCK, *v. n.* Welsh. *cloccian*; Armorick. *clochat*; Sax. *cloccan*; Dutch. *klocken*. To call chickens, as a hen.

She, poor hen, fond of no second brood,
Has *clucked* thee to the wars. *Shakspeare's Coriolanus.*

Ducklings, though hatched by a hen, if she brings
them to a river, in they go, though the hen *clucks*
and calls to keep them out. *Ray on the Creation.*

CLUE, the lower corner of a sail.

CLUE GARNETS, a sort of tackles fastened to
the clues, or lower corners of the main sail or
fore sail, to truss them up to the yard, which is
usually termed *cluing* up the sails.

CLUE LINES are for the same purpose as *clue*
garnets, only that the latter are confined to the
courses, whereas the former are common to all
the square sails.

CLUMP, *n. s.* formed from lump, a shapeless
piece of wood or other matter, nearly equal in its
dimensions. A cluster of trees; a tuft of trees
or shrubs: anciently a plump.

CLUMPS, *n. s.* a nunskull.

CLUMSY, *adj.* } This word omitted
CLUMSILY, *adv.* } in the other etymolo-
CLUMSINESS, *n. s.* } gists, is rightly derived
by Bailey from Dutch, *lompisch*, stupid. In
English, lump, clump, lumpish, clumpish, clump-
ishly, clumsily, clumsy. Awkward; heavy;
artless; unhandy; without dexterity, readiness,
or grace. It is used either of persons, or actions,
or things.

This lofty humour is *clumsily* and inartificially man-
aged, when affected. *Collier on Pride.*

The drudging part of life is chiefly owing to *clum-*
siness and ignorance, which either wants proper tools,
or skill to use them. *Id. on Fame.*

The matter ductile and sequacious, apt to be
moulded into such shapes and machines, even by
clumsy fingers. *Ray.*

He walks very *clumsily* and ridiculously.

Id. on the Creation.

But thou in *clumsy* verse, unlicked, unpointed,
Hast shamefully deify'd. *Dryden.*

That *clumsy* outside of a porter,

How could it thus conceal a courtier? *Swift.*

CLUNG. The preterite and participle of
cling.

CLUNG, *adj.* Sax. *clungu*, wasted with lean-
ness; shrunk up with cold.

CLUNG, *v. n.* Sax. *clungun*, to dry as wood
does, when it is laid up after it is cut. See *TO*
CLING.

CLUNIA, in ancient geography, a principal
town of Hither Spain, a Roman colony, with a
conventus juridicus, on the Durus, to the west
of Numantia, now called Corunna del Conde.

CLUNIE, a beautiful lake in Perthshire, with an island in the centre, in which stands an ancient castle, built about A. D. 1500, by George, bishop of Dunkeld, and now a summer residence of the family of Airly. Its walls are nine feet thick at the surface of the ground.

CLUNY, a town of France, in the department of Saone and Loire, and ci-devant province of Maçonnais, seated on the Grone. Before the revolution, it was famous for its Benedictine abbey, founded by William duke of Berry and Aquitain; or, as others say, by the abbot Bern, supported by that duke, A. D. 910. This abbey was so very spacious and magnificent, that in 1245, after holding the first council of Lyons, Pope Innocent IV. went to Cluny, accompanied with the two patriarchs of Antioch and Constantinople, twelve cardinals, three archbishops, fifteen bishops, and a great number of abbots; who were all entertained, without one of the monks being put out of their places; though St. Lewis the king, queen Blanche his mother, the duke of Artois, and his sister, the emperor of Constantinople, the princes of Arragon and a great number of lords, with all their retinues, were there at the same time. Cluny at its first erection, was put under the immediate protection of the apostolic see. It became the head of a very numerous and extensive congregation; and was the first congregation of various monasteries united under one chief; so as only to constitute one body, or, as they call it, one order. This order of monks was brought into England by William earl of Warren, son-in-law to William the Conqueror, who built a house for them at Lewes in Sussex, about the year 1077. There were twenty-seven priories and cells of this order in England, which were governed by foreigners, afterwards made denizens. Cluny lies ten miles north-west of Maçon, and forty-six N. N. W. of Lyons. Population 4200.

CLUPEA, the herring, in ichthyology, a genus belonging to the order of abdominales. The upper jaw is furnished with a serrated mystache; the branchiostege membrane has eight rays; a scaly serrated line runs along the belly from the head to the tail; and the belly-fins have frequently nine rays. There are fifteen species; the most noted are,

1. *C. alosa*, the shad, has a forked snout, and black spots on the sides. In Great Britain the Severn affords this fish in higher perfection than any other river. It makes its first appearance there in May, but in very warm seasons in April; for its arrival sooner or later depends much on the temper of the air. It continues in the river about two months, and then is succeeded by the variety called the twaite. The old fish come from the sea into the river in full roe. In July and August multitudes of bleak frequent the river near Gloucester; some of them are as big as a small herring, and these the fishermen suppose to be the fry of the shad. Numbers of these are taken near Gloucester, in those months only, but none of the emaciated shad are ever caught in their return. The Thames shad does not frequent that river till the end of May or beginning of June, and is esteemed a very coarse and insipid fish.

2. *C. encrasicolus*, the anchovy, has its upper

jaw longer than the under one, and is about three inches long. They are taken in vast quantities in the Mediterranean, and are brought over to Britain pickled. The great fishery is at Georgia, a small isle west of Leghorn. See FISHERY.

3. *C. herengus*, the common herring, has no spots, and the under jaw is longer than the upper one. A herring dies immediately after it is taken out of the water; whence the proverb, As dead as a herring. This fish is everywhere in great esteem, being rich, soft and delicate. Herrings are found from the highest northern latitudes, as low as the northern coast of France. They are met with in vast shoals on the coast of America, as low as Carolina. In Chesapeake Bay there is an annual inundation of these fish, which cover the shore in such quantities as to become a nuisance. We find them again in the seas of Kamtschatka, and probably they reach Japan; Kempser mentions, in his account of the fish of that country, some that are congenerous. The great winter rendezvous of the herring is within the arctic circle; there they continue for many months to recruit themselves after the fatigue of spawning; the seas within that space swarming with insect food in a far greater degree than those of our warmer latitudes. This mighty army begins to put itself in motion in the spring; we distinguish this vast body by that name: for the word herring comes from the German heer, an army, to express their numbers. They begin to appear off the Shetland Isles in April and May; these are only the forerunners of the grand shoal which comes in June; and their appearance is marked by certain signs, by the number of birds, such as gannets and others, which follow to prey on them: but when the main body approaches, its breadth and depth is such as to alter the appearance of the very ocean. It is divided into distinct columns of five or six miles in length, and three or four in breadth, and they drive the water before them with a kind of rippling. The first check this army meets in its march southward is from the Shetland Isles, which divide it into two parts: one wing takes to the east, the other to the western shores of Great Britain, and fill every bay and creek with their numbers; others pass on towards Yarmouth, the great and ancient mart of herrings; they then pass through the British Channel, and after that in a manner disappear. Those which take towards the west, after passing the Hebrides, where the great stationary fishery is, proceed to the north of Ireland, where they meet with a second interruption, and are obliged to make a second division: the one takes to the western side, and is scarce perceived, being soon lost in the immensity of the Atlantic; but the other, which passes into the Irish sea, feeds the inhabitants of most of the coasts that border on it. These migrations are made in order to deposit their spawn in warmer seas, which mature and vivify it more certainly than those of the frozen zone. It is not from defect of food that they set themselves in motion, for they come to us full of fat, and, on their return, are almost universally observed to be lean and miserable. What their food is near the Pole we are not yet informed: but in our seas they feed much on the *oniscus marinus*, a crustaceous

insect, and sometimes on their own fry. The young herrings begin to approach the shores in July and August, and are then from half an inch to two inches long; those in Yorkshire are called herring file. Some of the old herrings continue on our coasts the whole year: the Scarborough fishermen never put down their nets but they catch a few, but the number that remain are not worth comparison with those that return. See FISHERIES. The Dutch are most extravagantly fond of these fish when pickled. A premium is given to the first buss that arrives in Holland with a lading of this their ambrosia, and a vast price given for each keg. Flanders had the honor of inventing the art of pickling herrings. One William Beuklen of Biverlet, near Slays, hit on this useful expedient; from him was derived the name pickle, which we borrow from the Dutch and German.

4. *C. sprattus* has thirteen rays in the back fin. It is a native of the European seas, and has a great resemblance to the herring, only it is of a less size. They come into the river Thames below bridge in the beginning of November, and leave it in March; and are, during that season, a great relief to the poor of the capital. At Gravesend, and at Yarmouth, they are cured like red herrings: they are sometimes pickled.

5. *C. pileardus*, the pilchard. Nose turned up; dorsal in the centre of gravity; scales firm. Appears periodically in vast shoals, on the Cornish coast, about July; body thicker and rounder than the herring; smaller; the back more elevated, and the belly not so sharp nor so serrate; is more full of oil.

CLUSIA, the balsam tree, a genus of the monogynia order and polygamia class of plants: CAL. tetraphyllous or hexaphyllous, leaflet opposite and imbricated: COR. tetrapetalous or hexapetalous: the STAM. numerous. Nectarium of anthers or glandules coalesced, including the germs. The capsule is quinquelobular, quinquevalved, and full of pulp. There are six species, all natives of America. The most remarkable is the *C. flava*. It is pretty common in the British American islands, where the trees grow to the height of twenty feet, and shoot out many branches on every side, furnished with thick, round, succulent leaves, placed opposite. The flowers are produced at the ends of the branches, each having a thick succulent cover. They are succeeded by oval fruit. From every part of these trees there exudes a kind of turpentine, which is called in the West Indies hog gum; because they say, that, when any of the wild hogs are wounded, they repair to these trees and rub their wounded parts against the stem till they have anointed themselves with this turpentine, which heals all wounds. The plants are very tender, and, in this country, must be kept constantly in a stove and sparingly watered, especially in winter; for they naturally grow in those parts of the islands where it seldom rains, and consequently cannot bear much moisture. They may be propagated from cuttings, which must be laid to dry for a fortnight or three weeks, that the wounded parts may be healed over, otherwise they will rot. The best time for planting their cuttings is in July that they may be

well rooted before the cold weather comes on in autumn.

CLUSINA PALUS, in ancient geography, a lake of Tuscany, extending north-west between Clusium and Arretium, and communicating with the Arnus and Clanis. It is now called Chiana Palude.

CLUSINI FONTES, baths in Tuscany, in the territory of Clusium, between Clusium on the north and Aculi on the south, eight miles from each; now called Bagni di S. Casciana.

CLUSIUM, or CAMARS, in ancient geography, a town of Tuscany, at the south end of the Palus Clusina, where it forms the Clanis; the royal residence of Porsenna, three days' journey north from Rome. It is now called Chiusi.

CLUSIUM NOVUM, in ancient geography, a town of Tuscany, near the springs of the Tiber, in the territory of Arretium, where lies the Ager Clusinus; now called Casentino.

CLUSTER, *n. s. v. n. & v. a.* } Sax. *clýrpen*,
CLUSTERY, *adj.* } Dutch, *klister*.

A bunch; a number of things of the same kind, growing or joined together, as grapes on the vine; any number of creatures adhering together, as bees before they live; applied to numbers congregated, whether stars or human beings. The idea is union and connexion, by whatever attraction, of multitudes, constituting a body. To cluster, therefore, is to grow, or to collect together; to congregate.

Grapes will continue fresh and moist all winter, if you hang them *cluster by cluster* in the roof of a warm room. Bacon.

His armour green might seem a fruitful vine;
The *clusters* prisoned in the close-set leaves;
Yet oft between the bloody grape did shine,
And peeping forth, his jailer's spite deceives.

Fletcher's Purple Island.

Forth flourished thick the *clustering* vine, forth crept
The smiling gourd, up stood the corny reed
Embarled in her field. Milton.

As bees

Pour forth their populous youth about the hive
In *clusters*. Id. *Paradise Lost*.

The lascivious *clusters* of the vine
Upon my mouth do crash their wine. Mirvell.

There with their clasping feet together clung,
And a long *cluster* from the laurel hung. Dryden.

An elm was near, to whose embraces led,
The curling vine her swelling *clusters* spread. Pope.

My friend took his station among a *cluster* of mob,
who were making themselves merry with their betters.
Addison.

Or from the forest falls the *clustered* snow
Myriads of gems. Thomson's *Seasons*

The flowering glade fell level where they moved,
O'er arching high the *clustering* roses hung;
And gales from heaven on balmy pinion roved,
And hill and dale with gradulation rung. Beattie

Her glossy hair was *clustered* o'er a brow
Bright with intelligence, and fair and smooth. Byron.

CLUSTER-GRAPE, *n. s.*, from cluster and grape.

The small black grape is by some called the currant, or *cluster-grape*; which I reckon the forwardest of the black sort. Mortimer's *Peacocking*.

CLUTCH, *v. a. & n. s.* Of uncertain etymology. To hold in the hand; to gripe; to grasp; to comprise; to contract; to double the hand

so as to seize and hold fast. The plural substantive is generally applied to paws and talons, and to hands in a sense of rapacity and cruelty.

Is this a dagger I see before me,
The handle toward my hand? Come, let me *clutch*
thee. *Shakespeare.*

Not that I have the power to *clutch* my hand,
When his fair angels would salute my palm.
Id. King John.

They
Like moles within us, heave and cast about;
And, till they foot and *clutch* their prey,
They never cool. *Herbert.*

It was the hard fortune of a cock to fall into the
clutches of a cat. *L'Estrange.*

A man may set the poles together in his head, and
clutch the whole globe at one intellectual grasp.
Collier on Thought.

Your greedy slaving to devour,
Before 'twas in your *clutches* power. *Hudibras.*

Set up the covenant on crutches,
'Gainst those who have us in their *clutches*. *Id.*

I must have great leisure, and little care of myself,
if I ever more come near the *clutches* of such a
giant. *Stillingfleet.*

When suddenly (for such the will of Jove)
A fowl enormous sousing from above
The gallant chieftain *clutched*, and soaring high
(Sad chance of battle) bore him up the sky. *Beattie.*

Her glance how wildly beautiful! how much
Hath Phœbus wooed in vain to spoil her cheek,
Which grows yet smoother from his amorous *clutch*!
Who round the north for paler dames would seek?
How poor their forms appear! how languid, wan,
and weak! *Byron.*

CLUTIA, in botany, a genus of the gynandria order and diœcia class of plants; natural order thirty-eighth, tricoecæ: male CAL. pentaphyllous: COR. pentapetalous: STYLES three: CAPS. trilobular, with a single seed. There are ten species, all natives of warm climates. They are ever-green shrubby plants, rising six or eight feet, garnished with simple leaves and greenish-white quinquepetalous flowers. They are propagated by cuttings in spring or summer, planting them in pots of light earth, plunged in hot-heds. The plants must always be kept in a stove. The chief is *C. eleatheria*. Dr. Wright, in his account of the medicinal plants of Jamaica, says that this species is the same as the cascarilla and eleatheria of the shops. Other medical writers have supposed them to be distinct barks, and they are sold in the shops as different productions. Linnæus's *eroton cascarilla*, Dr. Wright observes, is the wild rosemary shrub of Jamaica, the bark of which has none of the sensible qualities of the cascarilla.

CLUTTER, *n. s. & v. n.* See CLATTER. A noise; a bustle; a busy tumult; a hurry; a clamor. A low word.

He saw what a *clutter* there was with huge, overgrown pots, pans, and spits. *L'Estrange.*

The favourite child, that just begins to prattle,
Is very humourous and makes great *clutter*,
Till he has windows on his bread and butter. *King.*

Prithee, Tim, why all this *clutter*?
Why ever in these raging fits. *Swift.*

CLUVIER, or CLUVERIUS (Philip), a celebrated geographer, born at Dantzie in 1589. He travelled into Poland, Germany, and the Netherlands, to study law; but being at Leyden, Joseph Scaliger persuaded him to cultivate his taste for geography. Cluvier followed his advice, and for this purpose visited the greatest part of the European states. He was well versed in many languages: and wherever he went obtained illustrious friends and protectors. At his return to Leyden he taught with great applause; and died in 1623, aged forty-three. He wrote 1. *De tribus Rheni Alveis*; 2. *Germania Antiqua*; 3. *Sicilia Antiqua*; 4. *Italia Antiqua*; 5. *Introductio in Universam Geographiam*. The first was written at Oxford.

CLWYD, a beautiful valley of North Wales, in Denbighshire, enclosed by high mountains, through which there are numerous gaps, and extending from the sea inwards above twenty miles, and varying in breadth from five miles to eight. This delightful vale is in high cultivation, even far up the sides of the hills; and is full of towns, villages, and gentlemen's seats. The climate is excellent, and the natives retain their vivacity to a very late period of life.

CLWYD, a river of North Wales, which rises in the middle of Denbighshire, runs through the vale of the same name, takes a compass to the south-east, then turns north-west, and, having entered Flintshire, falls into the Irish Sea.

CLYDE, a river in Scotland, which rises in Annandale, and running north-west through Clydesdale, by Lanark, Hamilton and Glasgow, falls into the sea a few miles below Greenock, over against the Isle of Bute. Next to the Tay, it is the largest river in Scotland; and is navigable for small craft up to Glasgow. The canal, which joins the Forth, falls into it a little below that city. The cataract called the Falls of the Clyde, opposite to Lanark, is a great natural curiosity, and the grandest scene of the kind in Great Britain. This tremendous sheet of water, for about a mile, falls from rock to rock. At Stonebyers the first fall is about sixty feet; the last, at Corra Lynn, is over solid rock, not less than 100 feet high. At both these places the great body of water exhibits a grander and more interesting spectacle than imagination can conceive. 'This great body of water,' says a traveller, 'rushing with horrid fury, seems to threaten destruction to the solid rocks. The horrid and incessant din, with which this is accompanied, unnerves and overcomes the heart. At the distance of about a mile from this place you see a thick mist, like smoke, ascending to heaven, over the stately woods. As you advance you hear a sullen noise, which soon after almost stuns your ears. Doubling as you proceed towards a tuft of wood, you are struck at once with the awful scene which suddenly bursts upon your astonished sight. Your organs of perception are hurried along, and partake of the turbulence of the roaring water. The powers of recollection remain suspended by this sudden shock; and it is not till after a considerable time, that you are enabled to contemplate the sublime horrors of this majestic scene.' The water-fall at Corehouse called Corra Lynn, is no less remarkable. The

banks of this river are adorned on both sides with woods, orchards, and elegant villas. In March 1787, and in the night between the 11th, and 12th of January 1797, a temporary subsiding or obstruction of the waters of this river took place, which occasioned no small speculation respecting the cause; some ascribing it to a subterraneous passage, by which the waters had run off. The phenomenon, however, was found to have been occasioned solely by the sudden freezing of a considerable part of the water, at the Shallows, between Boninton Lynn, and the Haughs opposite to the lands of Carstairs, where the river forms a vast extent of still-running water which is apt to be frozen when a very sudden and severe frost sets in, and to remain in that obstructed state for some hours, till the water above the shallows rise to such a height as to break through, and carry down these temporary dams of ice.

CLYDESDALE, a wild district of Scotland, in the south of Lanarkshire, famous for its lead mines, which lie mostly north and east, and afford also a considerable quantity of silver.

CLYMENE, in fabulous history, the daughter of Oceanus: and the mother of Phaeton, Lampetia, Ægle, and Phœbe, by Apollo. See **PHAETON**.

CLYPEOLA, treacle-mustard: a genus of the siliculosa order, and tetradynamia class of plants; natural order thirty-ninth, siliquose. The silicula is emarginated, orbiculated, compressed, plane, and deciduous. Species, one only, a native of France, Italy, and the warm parts of Europe, but hardy enough to bear the winters in this country.

CLYPEUS, in antiquity, a species of shield, of a round shape, usually formed of ox-hides, and smaller than the scutum. See **BUCKLER**, and the article **ARMOUR**.

CLYSSUS, in ancient pharmacy, an extract prepared from several bodies mixed. Among the moderns the term is applied to several extracts prepared from the same body, and then mixed together.

CLYSTER, *n. s.* $\chi\lambda\upsilon\sigma\tau\epsilon\rho$, an injection into the anus.

I have found, saith he [Hercules de Saxonia], by experience, that many hypocondriacal melancholy men have been cured by the sole use of *clysters*.

Burton's Anatomy of Melancholy.

If nature relieves by a diarrhœa, without sinking the strength of the patient, it is not to be stopp'd, but promoted gently by emollient *clysters*. *Archiebald.*

CLYSTERS, injections into the anus, usually administered by the bladder of a hog, sheep, or ox, perforated at each end, and having at one of the apertures, an ivory pipe fastened with pack-thread. But the French sometimes use a powder syringe, by which the liquor may be drawn in with more ease and expedition than in the bladder, and likewise more forcibly expelled into the large intestines. This remedy should never be administered either too hot or too cold, but tepid; for either of the former will be injurious to the bowels. Clysters are sometimes used to nourish and support a patient who can swallow little or no aliment, by reason of some impediment in the organs of deglutition. A kind of clyster,

made of the smoke of tobacco, appears to be of considerable efficacy when other clysters prove ineffectual, and particularly in the diarrhœa passion, in the hernia meæcerata, and for the recovery of drowned persons. See **ENEMA**.

CLYTEMNESTRA, in ancient history, the daughter of Jupiter and Leda. She married Agamemnon king of Argos, who, when he went to the Trojan war, left his cousin Egysthus to take care of his wife, his family, and domestic affairs. In the absence of Agamemnon, Egysthus made his court to Clytemnestra, and so completely succeeded that they lived publicly together. The infidelity of Clytemnestra reached the ears of Agamemnon before the walls of Troy, and he determined to take full revenge on the adulterers on his return. The execution of his schemes, however, were frustrated; Clytemnestra, with her adulterer, murdered him on his arrival, as he came out of the bath, or, as others say, as he sat down to a feast to celebrate his happy return. Cassandra, whom Agamemnon had brought from Troy, shared his fate; and Orestes would also have been deprived of his life if his sister, Electra, had not removed him from the reach of his mother. Having thus freed themselves of Agamemnon, they were publicly married, and Egysthus ascended the throne of Argos. Orestes, after an absence of seven years, returned to Mycena, determined to avenge the murder of his father. He concealed himself in the house of his sister Electra, who had been married by the adulterers to a person of mean extraction and low circumstances. His death was publicly announced; and when Egysthus and Clytemnestra repaired to the temple of Apollo, to return thanks to the gods for the death of the only surviving son of Agamemnon, Orestes who, with his faithful friend Pylades, had concealed himself in the temple, rushed upon the adulterers, and killed them with his own hands. They were buried without the walls of the city, as their remains were deemed unworthy to be laid in the sepulchre of Agamemnon. According to Æschylus, Orestes introduced himself with his friend Pylades at the court of Mycena, pretending to bring the news of the death of Orestes, and, when Egysthus enquired of the particulars, he murdered him, and soon after Clytemnestra.

CLYTHIA, or **CLYTHÉ**, daughter of Oceanus and Tethys, beloved by Apollo. She was deserted by her lover, who paid his addresses to Leucothoe; and this so irritated her, that she discovered the whole intrigue to her rival's father. She at length pined away, and was changed into a flower, commonly called a sun-flower, which still turns its head towards the sun in its course, in token of her love.

CNEORUM, in botany. See **CONVOULSUS** and **DAPHNE**.

CNESTIS, in botany, a genus of the decandria class, and pentagynia order: CAL. five-parted; petals five; CAPS. five, and bivalved; SEED single. Species four, natives of Sierra Leone and the west of Africa.

CNICUS, blessed thistle: a genus of the polygamia æqualis order, and synœnesia class of plants; natural order forty-ninth, compositæ:

CAL. ovate, imbricated with spinous branched scales, and enriched with bractæ: FLORETS, equal. Species fifty-four, of which the only remarkable one is that used in medicine under the name of *carduus benedictus*. This is an annual plant, cultivated in gardens. It flowers in June and July, and perfects its seed in autumn. For medical purposes it should be gathered when in flower, dried in the shade, and kept in a very dry airy place, to prevent its rotting or growing mouldy, which it is very apt to do. The leaves have a penetrating bitter taste, not very strong or durable, accompanied with an ungrateful flavor, from which they are in a great measure freed by keeping. Water extracts in a little time, even without heat, the lighter and more grateful parts of this plant; if the digestion be continued for some hours the disagreeable parts are taken up; a strong decoction is very nauseous and offensive to the stomach. Rectified spirit extracts a very pleasant bitter taste, which remains uninjured by time. The virtues of this plant are little known in the present practice. The nauseous decoction is sometimes used to provoke vomiting; and a strong infusion to promote the operation of other emetics. A stronger infusion, made in cold or warm water, if drank freely, and the patient kept warm, occasions a plentiful perspiration and promotes the secretions. The seeds of the plant are also considerably bitter, and have sometimes been used with the same intention as the leaves.

CNIDIA VENUS, a principal divinity of the Cnidians. Her statue was executed by Praxitelles; and was esteemed one of the finest productions of his genius.

CNIDUS, in ancient geography, a Greek town of Caria; situated on a promontory of a peninsula. It had in front a double port, and an island lying before it in form of a theatre, which, being joined to the continent by moles, made Cnidus a diopolis or double town. Eudoxus, the astronomer, had an observatory in Cnidus.

CNOSSUS, or **CNOST**, anciently called Cæratos, a city of Crete, twenty-three miles east of Gortina. Here stood the sepulchre of Jupiter, the famous labyrinth, and the palace of king Minos: its port, Hæraclæum, lay on the east side of the island.

COACERVATE, *v. a.* γ Lat. *coacervo* To

COACERVATION, *n. s.* γ heap together. The act of heaping, or state of being heaped, together.

The collocation of the spirits in bodies, whether the spirits be *coacervate* or diffused.

Bacon's Natural History.

The fixing of it is the equal spreading of the tangible parts, and the close *coacervation* of them. *Id.*

COACH, *n. s.* & *v. a.* γ Fr. *coche*; Ital. *co*
COACH-BOX, *n. s.* γ *chio*, *kotozy*; among
COACH-HIRE, *n. s.* γ the Hungarians, a
COACH-HOUSE, *n. s.* γ large covered carriage.
COACH-MAKER, *n. s.* γ The French *coche* sig-
COACH-MAN, *n. s.* γ nifies also a passage-
boat on a river. Bel. *koctze*, is a coach as well as a carriage. *Koatche* is said to signify with the Huns a high waggon. With us coach is a carriage of pleasure or state, distinguished

from a chariot, which is but half a coach. Stage-coaches are vehicles of a similar construction, for the use of the public, having their fixed periods of travelling, specific roads and distances, and certain fares agreed upon by the proprietors and their employers. Hackney coaches are vehicles let out for hire, whose sphere of operation is the metropolis and places within the hills of mortality; they are subject to strict and salutary regulations; it is imperative upon them to accept every fare that offers, and in case of dispute to yield to the first applicant.

COACH, or **COTCH**, is also a sort of chamber in a large ship of war near the stern. The floor of it is formed by the aftmost part of the quarter-deck, and the roof by the poop: it is generally the habitation of the captain.

Sudain upriseth from her stately place
The roiall dame and for he *coche* doth call. *Spenser.*

So forth she comes, and to her *coche* does clyme,
Adorned all with gold and girlands gay,
That seemed as fresh as Flora in her prime;
And strove to match, in roiall rich array,
Great Junoes golden chayre; and which they say
The gods stand gazing on when she does ride
To love's high house through heaven's bras-paved
way

Drawne of faire peacocks, that excell in pride,
And full of Argus' eyes their tayles dispredden wide.
Id.

Basilus attended for her in a *coach*, to carry her
abroad to see some sports. *Sidney.*

Her chariot is an empty hazel-nut,
Made by the joyner Squirrel, or old Grub,
Time out of mind the fairies *coach-makers*. *Shakspeare.*

Take care of your wheels: get a new set brought,
and probably the *coach-maker* will consider you. *Swift.*

Let him lie in the stable or the *coach-house*. *Id.*

Suppose that last week my *coach* was within
an inch of overturning in a smooth even way, and drawn
by very gentle horses. *Id.*

Thy nags, the leanest things alive,
So very hard thou lovest to drive;
I heard thy anxious *coachman* say,
It costs thee more in whips than hay. *Prior.*

A better would you nix?
Then give humility a *coach* and six. *Pope.*

The needy poet sticks to all he meets,
Coached, carted, trod upon; now loose, now fast,
And carried off in some dog's tail at last. *Id.*

My expences in *coach-hire* make no small article.
Spectator.

Her father had two coachmen, when one was in
the *coach-box*, if the coach swung but the least to one
side, she used to shriek.

Aruthnot's History of John Bull.

Another simile we mean to troach—
A new one too!—the stage is a *stage-coach*—
A *stage-coach*! Why?—I'll tell you if you ask it—
Here some take place—and some mount the basket.
Garrick.

Your late old *coachman*, though oft splashed by
dirt,
And out in many a storm remains unhurt;
Enjoys your kind reward for all his pains,
And now to other hands resigns the reins. *Id.*

London! right well thou knowest the hour of
prayer;
Then thy spruce citizen, wash'd artisan

And snug apprentice gulp their weekly air:
Thy *coach* of Hackney, whiskey, one-horse chair,
And humblest gig through sundry suburbs whirl
To Hampstead, Brentford, Harrow.

Byron. Child Harold.

COACHES are suspended on leather, and moved on wheels. In Britain, and throughout Europe, they are drawn by horses, except in Spain, where they use mules. In a part of the east, especially in the dominions of the great Mogul, coaches were very lately drawn by oxen. In Denmark they sometimes yoke rein-deer in their coaches; though rather for curiosity than use. About the beginning of the sixteenth century, according to professor Beckman, coaches of some kind were known; but their use was confined to women of the first rank; it being at that period considered disgraceful for men to ride in them. Thus the electors and princes of the empire, when they did not incline to attend the meetings of the states, made this their excuse to the emperor, that their health would not permit them to travel on horseback, and it was reckoned unbecoming to ride in carriages like women. It appears pretty evident however that about the end of the fifteenth century, the emperor, kings, and some princes, travelled in covered carriages; and likewise used them on particular public occasions. The nuptial carriage of the emperor Leopold's first wife, a Spanish princess, cost 38,000 florins, including harness. The coaches used by that emperor himself were covered over with red cloth and black mails; the harness was black, and no gold was to be seen in the whole work. The pinnels were glass. On festival days the harness was ornamented with fringes of silk. All the distinction betwixt the imperial coaches, and those of the ladies in the emperor's suite, was, that the former had traces made of leather, and the latter of ropes.

Carriages were early introduced into France. A statute of Philip the Fair, issued in 1294, for the suppression of luxury, prohibits the wives of citizens from the use of them. In England the oldest coaches used by the ladies were called whirlicotes, a name now sunk into oblivion. Richard II. towards the end of the fourteenth century, when obliged to fly before his rebellious subjects, travelled with all his attendants on horseback; his mother alone, who was indisposed, riding in a coach. And even this afterwards became unfashionable, the daughter of Charles VI. showing the ladies of England, with what ease she could ride on a side-saddle. Coaches first came into use in England, according to Stow, about the middle of the sixteenth century, being introduced from Germany by the earl of Arundel. In 1598 the English plenipotentiary went to Scotland in a coach; and about 1605 they were generally used. Plenipotentiaries first appeared in coaches at the imperial commission held at Erfurt, in 1613; and in 1681 no fewer than fifty gilt coaches were to be seen at the court of Ernest Augustus of Hanover. They have since been gradually brought to perfection. Louis XIV. of France made several sumptuary laws for restraining the excessive richness of coaches, prohibiting the use of gold, silver, &c. therein.

A coach has been defined, a convenient carriage suspended on springs, and moving on four wheels

intended originally for the conveyance of persons in the upper circles of society, but now become very common among other classes, in almost all civilised countries. In London, upwards of a 1000 hackney coaches are daily employed for the conveyance of its citizens and residents from one place to another; and in Bristol, Liverpool, and Birmingham, coaches of the same kind are used.

The fashion with regard to the form and ornament of coaches and other carriages for pleasure, is perpetually changing; the chief kinds now in use, are the close coach, the landau, which can lower its roof, and part of its sides, like the head of a phaeton; the barouche, or open summer carriage, made on the lightest construction; the chariot, which is intended only for two or three persons; the landaulet, or chariot, whose head unfolds back; the phaeton and caravan, which have only a head and no windows, with a leather apron, arising from the foot-board to the waist. These all run upon four wheels.

Of the two-wheeled vehicles, there is the curriole drawn by two horses, each bearing on a narrow saddle, the end of a sliding bar or yoke that upholds a central pole; the gig, chaise, or wiskey that have each only one horse, which moves between a pair of shafts, borne nearly horizontally, by means of a leathern sling passing over the saddle tree. When a gig, &c. has two horses, one preceding the other in harness, the machine and its horses taken together are denominated a tandem, a latin word signifying, at length. This is always a very questionable sort of vehicle for safety, especially in crowded streets or ways; but the management of it is not to be compared, certainly with another effort of noble daring which the great and scientific supplement to the Encyclopædia Britannica records. 'We have seen a vehicle, says a writer in that work, called a suicide, from the extreme danger of driving it; and there are some aspiring youths, who have far eclipsed all their competitors, by driving through the most crowded streets in very high carriages, drawn by two horses, the one before the other, supported on one narrow wheel!'

Coaches, Mail, are stage coaches of a particular construction, carrying his Majesty's mails, which are protected by a guard, and subject to the regulations of the post-office. Until the year 1794, letters were conveyed from the metropolis to distant parts of the kingdom, and vice versa, by carts with a single horse to each, or by boys on horseback; in consequence of which many robberies were committed, delays occasioned, and losses sustained. At this period John Palmer, esq. afterwards comptroller general of the post-office, devised a new plan, which he recommended to government, as calculated to increase the revenue, accommodate the public, and be highly advantageous to all parties. It was to provide a certain number of coaches of light construction; each to be adapted to carry the various bags or packets of letters, which were destined for a particular part of the country, or line of road. All the coaches, drawn by four horses, were to leave London precisely at eight o'clock in the evening, to travel at the rate of eight miles an hour, including the time allowed for change of horses, &c. and to arrive at and leave certain post-towns at

specific times. Each coach is provided with a coachman, a guard with fire-arms, an excellent time-piece set by the Post-office clock, and allowed to carry four passengers inside and two outside. The systematic regularity, punctuality, superior safety, and expedition of the mail-coaches of England render them superior to any other public conveyance in Europe. Every coach on its arrival in town is sent to the contractor's yard for inspection, as to its condition, so that no one returns to its business liable to those accidents through want of examination that frequently occur to other coaches. The property and profits of the post, or the conveyance of letters, are vested in government, which contracts with the proprietors of coaches for the carriage of the mail; but these proprietors derive their chief profit from the fare of passengers, and carriage of small packets. The mail coaches are said to run above 13,000 miles daily. There is a similar establishment in Ireland. By 50 Geo. III. c. 48: if the coachman, or any other person having the care of the mail coach or any other carriage, shall permit any other person, without the consent of a proprietor, or against the consent of the passengers, to drive the same, or quit the box without reasonable occasion, or for a longer space of time than such occasion may require (though the reins be left for the time in the hands of the passenger on the box): or, if the coachman, or person having the care of the coach, shall by furious driving, or any negligence or misconduct, overturn the carriage, or in any manner endanger the persons or property of the passengers, or the property of the owners or proprietors of such carriage (unavoidable accidents excepted) every such coachman or person so offending, shall for every such offence forfeit not exceeding £10, nor less than £5. If the guard of a mail coach or other carriage shall fire off his arms, except for self-defence, he shall forfeit £5.

COACHES, STAGE, in Great Britain, as undertaking the conveyance of persons and parcels from one place to another, have been made the subject of various legal injunctions and provisions. Under the Commissioners of Stamps they are subject to certain mileage duties, 55 Geo. III. c. 185.

As carriers, stage-coachmen (but not Hackney coachmen of London), come under the general law of 'all persons carrying goods for hire;' and are chargeable in a limited way, with all the faults and mis-carriages of their servants. But, 1. A price must be paid, or contracted to be paid. In an action against a master of a stage-coach, the plaintiff set forth, that he took a place in the coach for such a town, and that in the journey the defendant, by negligence, lost the plaintiff's trunk; upon not-guilty pleading, the evidence was, that the plaintiff gave the trunk to the man who drove the coach, who promised to take care of it, but lost it; and the question was, whether the master was chargeable; and adjudged that he was not, unless the master takes a price for the carriage of the goods as well as for the carriage of the person, and then he is within the custom as a carrier: that a master is not chargeable for the acts of his servants, but when they are done in execution of the authority given by the master, then the act of the servant

is the act of the master. 1 Salk. 282. And 2. By the custom and usage of stages, every passenger pays for the carriage of goods above a certain weight; and there the coachman shall be charged for the loss of goods beyond such weight. 1 Com. Rep. 25. 3. In order to charge a stage-coach proprietor or carrier with the loss of goods, regard must be had to any special notice or understanding between the parties. A person delivered to a carrier's book-keeper two bags of money sealed up, to be carried from London to Exeter, and told him that it was £200, and took his receipt for the same, with promise of delivery for 10s. per cent. carriage and risk: though it be proved that there was £400 in the bags, if the carrier be robbed he shall answer only for £200, because there was a particular undertaking for the carriage of that sum and no more, and his reward, which makes him answerable, extends no farther. Carth. 486. Or, A sends goods to B who says, he will warrant they shall go safe; he is liable for any damage sustained by them, notwithstanding A sends one of his own servants in B's cart to look after them. 2 B. and P. 416.

And where the owner of a stage-coach puts out an advertisement 'that he would not be answerable for money, plate, or jewels above the value of £5, unless he had notice, and was paid accordingly,' all goods received by that coach are under that special acceptance; and if money or plate be sent by it without notice, and being paid for it, if lost, the coach owner is not liable: *Gibbon v. Paynton*, 4 Burr. 2298. *Izett v. Mountain*, 4 East, 371. *Nicholson v. Willan*, 5 East. 507. Not even to the extent of the £5, or the sum paid for booking, *Clay v. Willan*, H. Black. Rep. 298.—In these cases a personal communication is not necessary to constitute a special acceptance.—Advertisements, notices in the warehouse, and hand-bills, which it is probable the plaintiff saw, or which he might have seen, are sufficient.

For the protection of persons travelling by stage-coaches, the salutary provisions of 50 Geo. III. c. 48. are. That a carriage with four or more wheels, and drawn by four or more horses, shall be allowed to carry ten outside passengers and no more, exclusive of the coachman, but including the guard; and one passenger only shall be allowed to sit upon the box with the coachman, three on the front of the roof, and the remaining six behind, on any part, except on the luggage, or that part of the roof allotted for the same. Carriages drawn by two or three horses shall be allowed no more than five outside passengers, exclusive of the coachman; and all stage coaches, called long coaches, or double-bodied coaches, shall carry no more than eight outside passengers, exclusive of the coachman, but including the guard, if there be any, under such fines and penalties as are imposed by the act: provided that no child in the lap, or under seven years, shall be accounted one of this number, unless there be more than one; and if more, two such children shall be accounted equal to one grown person, and so on in the same proportion; and that no person paying as an outside passenger shall be permitted to sit as an inside passenger, unless

with the consent of one at least of the inside passengers, next to whom he shall be placed; provided also, that when the construction is peculiarly wide or commodious, and being so found shall be duly licensed for that purpose, four outside passengers shall be allowed to sit on the front of such carriage; but outside passengers shall never exceed ten in all.

No proprietor or driver of any such carriage, travelling for hire, shall permit any luggage to be carried on the roof, or any person to go as outside passenger on or about the outside of any such carriage, the top of which shall be more than eight feet nine inches from the ground, or the bearing of which on the ground shall be less than four feet six inches from the centre of the track of the right or off wheel, to that of the track of the left or near wheel, under the penalty of £5 for each offence. No luggage whatever, exceeding two feet in height, shall be conveyed on the roof of any carriage, if drawn by four or more horses; and, when drawn by two or three horses, such luggage shall not exceed eighteen inches above the roof, under the penalty of forfeiting £5 for every inch above two feet or eighteen inches respectively; if the driver so offending shall be the owner, he shall forfeit £10 for every inch above the measure above assigned, and, in default of payment, the person or persons so offending shall be committed to the common gaol or house of correction of the county, &c. where the offence was committed, for two months, unless such penalties be sooner paid; provided always, that all packages be so placed on the roof, that no passenger shall sit on them, under the penalty of 50s. for each offence, to be paid by each such passenger; and the division or space on the top allotted for luggage, shall be distinctly separated from the other part of the top, by some railing or otherwise. However, luggage may be carried of a greater height than two feet, if not more than ten feet nine inches from the ground.

The number of passengers permitted to be carried, shall be specified in the licence, and painted on the doors of the coach in legible characters; and commissioners for granting licences may order a cross plate on the side of each coach, with the owner's name, &c. instead of the above inscription; the penalty for defacing, &c. such inscription is a forfeiture of £5, and every person offending against the provisions of this act, by not having a licence, by omitting the inscription, or carrying more outside passengers than are specified in the licence and in the inscription, as above, shall for every offence forfeit £10 for each outside passenger beyond the number allowed, and double that sum if the driver or coachman be owner or part-owner. The owners of stage-coaches shall be liable to penalties if drivers cannot be found, provided that the owners cannot prove to the satisfaction of the magistrates before whom the information is laid, by sufficient evidence independent of his own testimony, that the offence was committed by the driver without his knowledge, and without any profit accruing to himself; and the driver, when found, shall pay the penalty, or be committed to the common gaol or

house of correction, for not less than three, and not more than six months.

The penalty on a driver for using abusive or insulting language to any passenger, or exacting more than his fare, is a forfeiture of not less than 5s. nor more than 40s., or a commitment for any time not exceeding one month, nor less than three days, at the discretion of the magistrate. Passengers are empowered to require toll-collectors to count the number of passengers, and to measure the height of the luggage; and the driver refusing to stop for this purpose, shall forfeit £5 for every such refusal, and if more passengers are carried than the act allows, or the luggage exceed the height assigned by it, he shall forfeit double the penalty imposed by this act for such offence, one-half to the collector for his trouble and the other half to the passenger; and if the toll-collector, upon being required by such passenger, shall refuse to make such examination, he shall forfeit £5 for every such offence; and if any person shall endeavour to evade such examination, by descending from such carriage previously to its reaching any rampike gate, and re-ascending after it has passed such gate, he shall forfeit £10. But stage-coaches carrying no parcels or luggage inside, or in the boots, or under their beds, having obtained special licence, may carry two extra passengers.

All prosecutions must be commenced in fourteen days; persons aggrieved may appeal to the sessions. This act is a public act. And quoted in the clause respecting mail and other coaches above.

COACH-MAKING. Coach-making is an art which has, within the last fifty or sixty years, been carried to a very high degree of perfection. Coach and coach-harness makers, though of different professions, in some respects, are privileged by each other to follow either or both trades. The coach-maker is generally understood to be the principal in the business, being the person who makes the wood-work. There are, however, but very few professions in which a greater number of artisans are necessarily employed, such as wheelwrights, smiths, painters, carvers and gilders, carriers, lace-makers, woollen cloth manufacturers, and many others. We shall therefore follow this art through its various branches with some particularity of detail.

It is a first and obvious rule, that carriages of every kind should be adapted, not only to the different uses, but also to the different places for which they are intended. The best possible carriage for the paved streets of London, and other large towns, is not the most proper for country use, and one that is adapted to the excellent roads of England, would be unsuitable for the traveller on the Continent. The construction of every carriage should be as *light* as the nature of the place it is destined for, and its necessary work will admit; superior strength can only be effected by addition in the weight of materials, which a regard to the horses will make a person very careful not unnecessarily to increase. The great art then consists in building as light as possible, yet so as sufficiently to secure the carriage from danger. What a light carriage may lose by wearing a shorter time than one much

heavier, is more than compensated by the preservation of the horses.

The general form of structure in a carriage depends much on fancy, while the size must be proportioned to the intention, and regulated by the width of the seat, and the height of the roof. The timbers of the body should be of dry ash, and formed with great exactness; the pannells are made of soft straight-grained mahogany, smoothed to a fine surface, and fitted or fixed in prepared grooves, or bradded on the surfaces of the framing: the insides are to be well secured by gluing, blocking, and canvas, to the pannells; the roof and lining, or inner parts, are made of deal boards. As no parts of the framing of the body, if well executed, are likely to fail by use, a reparation in consequence of accidents is all that is to be expected.

The *pannels* generally suffer most injury, either from excessive heat, or from the bad quality of the timber: of course great attention is required in selecting good boards for this article, which, if not dry and well-seasoned, are sure to fail by drawing from the grooves, bulging, or cracking: Even though the timbers are good, if the carriage is exposed to any excess of hot weather, it is a great chance but they will fly: but no discredit ought to attach to the builder from that circumstance. The first summer a carriage is used will prove the sufficiency of the pannells. So soon as they begin to start from the grooves, as they mostly will, in some degree, the builder should examine and relieve them where confined, to prevent cracking. A little drawing from the grooves is to be expected, and is of no material consequence; but, if they crack, it will be a disagreeable object to the eye.

As sufficient room in the carriage makes the *seats* comfortable, its capacity should be the first object, and the width of the body ought to be in proportion to the number it is meant to accommodate. Open bodies have this advantage, that three can sit with tolerable ease on the same length of seat, as would accommodate two in a confined one. A full-sized seat for a close body to contain three persons, is about four feet one or two inches; that of an open body, three feet five or six inches. This latter size is sufficient for two persons in a close carriage, but a seat of from two feet seven inches, to two feet eight or ten inches, is sufficient in the open bodies. The width across the seats is never regular, but is adapted to the shape of the body. The usual width is from fourteen to eighteen inches. The height of the seat from the bottom is in general fourteen inches, and from the seat upward to the roof, from three feet six inches to three feet nine inches, without the cushion. It frequently has been found convenient to make the seat moveable, to give freedom to certain head-dresses. Few people rise above three feet from the seat, so that, allowing two inches for the cushions, there is left in the clear, without the head-dress, from four to seven inches.

The *bodies* of a post-chaise and chariot do not differ from each other, but the purposes for which they are intended alter their name. The chariot is distinguished from the post-chaise, by the addition of a coach-box to the carriage part. The

post-chaise being intended for road work, and the chariot generally for town use. The materials of carriages meant for post work only, are somewhat lighter than those of a town carriage; but, when alternately used, the strength must be sufficient for either. The framings are not required to be so strong for one or two, as for three persons. If a carriage is generally used for three, the length of the seat should be from four feet to four feet one or two inches; but if only for a third person, occasionally, three feet eight inches will be sufficient, with a seat to draw out from the centre. A greater width is usually allowed at the front, than at the back of the seat, to render it more commodious for the elbows. The door-lights or windows are frequently contracted on the seat-side, that the passengers may be more secure from outward observation, while at the same time there is a sufficient view from within. The following is a description of a body complete in all its parts, as given by Mr. Felton in his excellent work on this subject.

The upper parts, except the roofs, are generally called upper quarters, that is side and back quarters. The usual mode of finishing these is by filling the vacancy with deal boardings, firmly battened on the inside, and covering the surface with leather, tightly strained on, and nailed at the inside edges; over which a moulding goes, and is sewed at the outside edges, making a welt, or is nailed in a prepared rabbet, and covered also with mouldings. Other quarters have the vacancy, the pillars, and rails covered with a pannel or mahogany board, finely smoothed on the outside. The leathery surface is the most secure; the pannel surface looks the best; but the brads with which they are confined, and the other nailings of the head-plates, mouldings, &c. occasion them frequently to split.

The sword-case is prepared in the same manner as the quarters, either with a leather or mahogany surface.

The lower side pannells are put in an improved rounded form. It adds considerably to the fullness of the side, and exhibits the painting thereon to a much greater advantage; this is done by the door and standing pillars being left full on the outsides, and reduced by rounding them towards the bottom.

The inside work, where the glasses are contained in the front and doors, is only lined or cased with the boardings, and nailed in rabbets on those pillars which form the lights or windows; the other inside work is battening, blocking, and gluing of canvas along the edges, and across the grain of the pannells, which gluing very much preserves and strengthens them. The blocking is also a material assistance to the strength, which is done by a half-square, cut across or angle-ways, cutting it also in short lengths, and gluing the square sides against the pannel and its framing.

The battens are long thin pieces of board, placed across the grain of the wood, bradded or secured by blocks or canvas, in order to strengthen or support those parts to which they are applied.

The inside work, after being thus finished, should be immediately painted all over, except

the seats, and, in particular, the door and front pannels, before the lining-boards are fixed in, so as to expose no timber to the air uncovered with paint, as the air materially affects it, particularly the wide boards or pannels. They swell in wet, and shrink in dry seasons; a proper attention, in this particular, is indispensably necessary.

It may here be observed that the coach has no fore pillar like the chariot, because it has no windows in front. The bodies of the landau and landalet differ nothing in shape from those already mentioned. The landau is of the coach, the landalet of the chariot form. The weight of these is so much greater than that of the carriages in their simple structure, that they are now but seldom used. The difference, however, excepting additional strength of timber, is only from the middle rails upward, to which height the doors open. It is usual to add a spring-bolt on that side of the door which shuts, to prevent its being opened when either the glass or shutter is up.

In open carriages, as phaetons, curricles, &c. there is so great a variety of forms, that no general rule can be observed in building them, but they are mostly fashioned according to the fancy of their owner. Those intended for single horses are for the most part light, the length of the seat is generally adapted for two persons only, those for two horses are made of stronger timbers, and are more roomy. The method of hanging the bodies depends also on fancy, or a conception of ease: and some bodies are not hung at all, but fixed on the shaft of the carriage, depending entirely for their ease on the springs which are fixed underneath, and which support the shafts on the axletree. The heads to some open bodies are permanently fixed, and others are made to take off, but the addition of their weight, and their great expense, frequently render their use objectionable. The gig body is principally used in a curriole, or handsome chaise carriage. The hind loops, which suspend the weight, are fixed through the corner pillars. The method of hanging at the fore-part varies according to the taste and judgment of the builder, or the situation of the body. The side pannels may fill the space between the two pillars, but, in conformity to the present mode of building, the side is divided at the standing pillar by a door, or an imitation thereof, preserving the same shape. In either case, whether a sham or real door, it projects above the surface of the pannels. The size of the body varies according to the purposes for which it is intended, but in general the measure is from two feet ten inches to three feet two inches on the seat.

Though the word *four-wheeled* carriage usually implies a carriage complete, yet it is distinguished among builders as the under part only, or frame with the wheels, on which the body is placed. It is the carriage which bears the stress of the whole machine, and, of course, every thing depends on its strength. It should be well proportioned, according to the weight it is meant to support, always allowing rather an over than under proportion, to avoid the risk of accidents. A proper application of the iron work to support the pressure is a thing materially to be attended

to, and great care should be taken that there are no flaws in it. The timbers, which are of ash, should be of young trees, of the strongest kind, free from knots, and perfectly seasoned before they are used; as many parts of the framing are obliged to be curved, it is best to select such timbers as are grown as nearly as possible to the shape. The workmanship must be strong and firm, and not partially strained in any of its parts, as it is liable to much racking. The timbers throughout are lessened or reduced, for the sake of external appearance, which appearance is assisted also with moulding edges and carving.

All four-wheel carriages are divided into two parts; the upper and under carriage. The upper is the main one on which the body is hung, the under carriage is the conductor, and turns by means of a lever, called the pole, acting on a centre pin, called the perch bolt. The hind wheels belong to the upper part, the fore wheels to the under.

Of four-wheel carriages there are two sorts, the perch and crane-neck, in which there is a material difference in the building and properties, but this does not affect the bodies, as they will hang equally well on either. The perch carriage is of the most simple construction, and lighter than the crane-neck; and, as the width of the streets in London gives every advantage to their use in turning, they are the most general. The crane-neck carriage has by much the superiority for convenience and elegance, and every grand or state equipage is of this construction; but the weight of the cranes, and the additional strength of materials necessary for the support, make carriages of this sort considerably heavier than the other.

The track in which the wheels of every carriage are to run is generally the same, except when intended for particular roads, in which waggons and other heavy carriages are principally used: these leave deep ruts, in which light carriages must likewise go, or be liable to accident. All four-wheel carriages should have the hind and fore wheels to roll in the same track; the ordinary width of the wheels is four feet eight or ten inches, that of waggons or carts generally measure more than five feet, to which chaise wheels (being principally intended for the country) are adapted. It is immaterial to what width wheels are set, if used for running upon stones, but upon soft and marshy roads, if exactness is not attended to, the draught is considerably increased. The different heights of the hind and fore wheels make also a difference in the length of their axletrees, agreeably to the proportion they bear to each other, the fore wheel has the longest axletree by one or two inches between the shoulders.

The length of the carriage is regulated by the size or length of the body which it is intended to carry; but it always takes its measure from the centres of the hind and fore axletrees. In general, a perch-formed carriage measures nine feet two inches for a chariot, and nine feet eight inches for a coach; but in a crane-necked carriage, on account of the bow for the wheels to pass under the measure, in a chariot is nine feet six inches, in a coach ten feet.

We shall now give a more particular account of the perch described by Mr. Felton; and afterwards explain the nature of Mr. Edward Stracey's invention for an improved method of hanging the bodies, and of constructing the perches of four-wheeled carriages; by which, he says, such carriages are less liable to be overturned, and for which invention he obtained, some years since, his majesty's letters patent.

The perch is the main timber of the carriage, which extends through the hind and fore springs, transom, or bars. By it the principal part of the upper carriage is supported. The hind part is supported, and united to it, by means of hooping two extended timbers, called wings, on the side. The fore end is fixed or united to the perch by means of a strong piece hooped at the top, and framed through the fore transom, called a hooping piece: but some carriages have a horizontal wheel in the front, the same as the crane-neck carriages; and these have no hooping piece to the perch, but are secured by means of side-plates. Those on the general principle have, at the bottom in front, a flat piece, left extended, called a tongue, which goes through a large mortise in the fore axletree bed, and through which the perch-bolt passes: its use is to keep the fore axletree bed steady in its place.

Sometimes the perch is made of a bent form, called a compass perch, for the purpose of admitting the body to hang low, or to form a more agreeable line to the shape thereof; those perches are of a very ancient form, but are now revived with considerable improvement from their original shape, and are become the prevailing fashion. When the carriage is intended for a wheel or horizontal wheel, the perch has no hooping-piece, but is bolted by the plates at each end to the inside of the transoms.

Plating with iron the sides of perches is a great improvement, and is now most generally done, and always must be, to those compass perches, if required to be light in their appearance, as the size of the timber is so much reduced by cutting them to this shape. To the straight or compass perch, iron plating on the sides is a great addition, as it will admit the timbers to be so much reduced, that a sufficient strength is preserved, though but half the usual size; the plates, as fixed edge-ways to the sides of the perch, will support ten times more weight than if flat-ways at the bottom, which is the method of plating a perch in the plain or common way; and many of those carriages which are made up for sale, have even the bottom plate omitted; but the certain consequence of this superficial method is, the sinking or settling of the perch, whereby the carriage is contracted quite out of its form, to the great injury of it, both for use and appearance, and there is no remedy but by a new one.

Mr. Stracey's invention embraces four objects.

1. The constructing of the perch of a four-wheeled carriage, in such a manner, that either of the axletrees may have a vertical motion independent of the other: so that the axletrees may be in different planes at the same time. 2. The hanging of the body on the springs of such a carriage, in such a manner as will tend not only to diminish the liability of its being overturned,

but add also to the ease of its motion. 3. The forming a collar-brace, which shall almost immediately bring the body to an equilibrium, should the centre of gravity be moved. 4. The forming a perch-bolt, by the use of which the carriage may be more easily turned to the right or left, and the friction that now takes place, by the use of the common perch-bolts between the wheel plates, the transom bed, and the fore axletree bed, reduced almost to nothing.

The principal variation of this invention, from the common method of hanging the body on its springs, consists in the body-loops, which must be so extended, that the ends of them may come nearly under the shackles of their respective springs, and each of them so formed, as to end in a cylindrical axis of one to two inches or more in length, and of sufficient strength to support the body: and on each of these body-loop axes, a shackle, for the reception of one of the main braces, should be fitted, ending in a cylindrical box or roller, made so as to work and turn on the axis of the body-loop, and secured to it by a nut and pin; and the connexion between these shackles and their respective boxes should be by means of a strong joint, working towards the front and hind part of the carriage in the direction of the perch. The body is to be hung by the main braces, attached to these shackles on the springs, in the same manner as other carriage-bodies are usually hung. When the body is thus hung, the action is as follows: should either of the hind or fore wheels descend into a low spot in the road, or ascend a raised surface, the boxes or sockets on the body-loops will turn on their axes, and keep the whole on a proper equilibrium, so as not to be overturned.

Another part of the invention is the application of a cylinder to the collar-braces of carriages, by means of which, should the centre of gravity of the body of the carriage be moved by any inequalities in the road or otherwise, either to the right or left, the equilibrium will be almost immediately restored by the motion of the cylinder, or roller on its axis, and the consequent lapping and unlapping of the straps; for to whichever side the body is impelled, on that side will the collar-brace be lengthened, and of course the opposite collar-brace proportionally shortened; one side is made to operate as a check upon the other, in order to bring the body to its true centre. The last part of the invention is the perch-bolt, which being properly placed, the fore axletree bed may be turned either to the right or the left, with much greater ease than if the common perch bolt were made use of, the usual friction between the beds and wheel-plates, being almost wholly removed from their being gradually separated by the lifting of the screw, in the act of turning.—See *Repertory, New Series*, vol. xiv.

The timbers of the crane neck carriage, are of the same description as those of the last, excepting the perch and hooping timbers, which are not used. The hind and fore ends are fixed to the cranes, which makes the bearings more steady than those of a perch carriage. The whole will be better understood by the following description:—

Fig. 1, plate COACH-MAKING, is an elevation of a crane-necked coach complete; fig. 2 is a front view of it, showing the fore wheels and under carriage; and fig. 3 is the horizontal plan of the same, many parts of this are too evident and universally known to require any reference, as the wheels, the body, the coach-box, the boot, the springs, &c. *a, a*, are the two cranes which are made of iron, and answer in their use to the wooden perch of the common carriage, which is the main timber of the carriage, extending and connecting the hind and fore-spring transom *D D*, and *E E*, or cross-bars which support the springs *F F* and *G G*, and thus forming one frame called the upper carriage, in which the body is suspended. The two iron cranes *a, a*, form the same connexion, but in a more complete manner, and they have a bend or neck at *b*, which admits the fore wheels to pass under them when the carriage is turned short about; the cranes are united to the fore carriage, by being screwed fast into the fore spring transom *D*, and they are farther screwed by clipping them down to a cross timber near *A*, in fig. 1, and marked *B* in fig. 3, it is called the budget bar, from the circumstance of its bearing the boot or budget, and it has two pieces *A*, called nunters, framed into it, which connect it with the fore transom, *D*, these pieces make a platform or frame, on which the budget immediately rests; the springs, *F*, are bolted to the transom, at the lower end, and have an iron brace *F*, fig. 1, called the spring stay.

The fore transom, or fore spring bar *D*, is the most essential part of the cross framing, it is a strong timber to which the cranes are fixed, by passing through it as before mentioned, therefore, an under carriage is attached thereto, by means of a large, round, iron pin *d*, fig. 3, which passes through its centre; on the bottom is a thick flat plate; made flush to the edges, called the transom plate, on the ends the springs are fixed, and on the top the boot, or the blocks that support it, are rested. *E* is the hind transom, or hind spring bar, something similar in its use to the fore transom, but not required to be of such strength; to this the ends of the cranes are fastened, and the timbers called nunters, which run parallel with them, are framed into it, and unite it with the hind axle bed *H*, on the ends the springs *G, G*, are fixed; the blocks or pump-handles, *I I*, are placed on the top to support the foot board *K*, or platform, and the footman's step-piece bolted on the outside. *H* is the hind axletree bed, it is a strong timber which receives the axletree, the cranes, *a, a*, as before mentioned, are securely fastened to it, and it is connected by two pieces called nunters, as before mentioned, with the bend transom *E*; the bottom is grooved to receive the axletree, which groove is called the bedding of the axletree, but is usually bedded at the ends only. At the two ends of these timbers are left projections called cuttoos, which cover the top or back ends of the wheels, to shelter the axletree arms from the dirt, which would otherwise get in behind the wheels, and clog them. *J, J*, are the hind blocks, which are called pump-handles; when further extended than what is here represented, they are frequently

called raisers, as their use is only to heighten the platform from the hind framings, that the appearance may be light, and that the footman may be sufficiently raised, according to the height of the body; they are bolted on the axletree bed and spring bar *F*, and, to prevent the too heavy appearance, they are often neatly ornamented with carving.

The footboard or platform *K*, on which the cushion for the servant stands, is a flat thick elm board, bolted on with blocks, to which it is also screwed. *L*, the boot, a large box made of strong elm board, nailed and screwed together, having a door in the front, which door should be made framed and boarded, and confined by a bolt and thumb nut; the surface of this boot should always be covered with a russet, or japanning leather; it is bolted across the transom *D*, the boot or budget bar *B*, and fore blocks as shown in fig. 1; and is sometimes raised on side blocks, to lighten the appearance of the fore end of the carriage. The parts marked *M N O P*, including the fore wheels, are called the fore or under carriage, united to the upper carriage by the perch bolt. *M*, the fore axletree bed, which is required to be a strong piece of timber, in which the fore axletree is bedded; on this the upper carriage rests. In this timber the futchels, *NN*, are fixed; it is also cultivated on the end, the same as the hind bed. *NN*, the futchels, are two light timbers, fixed through the fore axletree bed, contracted in the front, to receive the pole *O*, which part of the futchels is called the chaps; but they widen towards the hind end, on the top of which the horizontal circle *P C* is placed, with proper blocks to raise it.

Across the fore ends of the chips of *NN*, the splinter board *P* is fixed; the futchels are framed in a slant direction, to give a proper height to the pole; they have iron braces beneath; but sometimes the futchels are framed in a horizontal direction, and are made to rise in a cant from the front of the horizontal wheel, otherwise the pole must be compassed to raise it to a proper height. *P*, the splinter bar, is a long timber to which the horses' traces are attached; on the ends are sockets, with eyes, on which the wheel-irons *g* are placed, and extend from thence to the ends of the axletree arms, holding the splinter-bar tightly back to oppose the strain of the draught, which is taken from the axletrees at the ends by the wheel-irons, and at the middle from the futchels, proper roller bolts. *h h*, being fixed at these situations to receive the traces by which the horses draw.

c c, The horizontal circle called a whole wheel front; it consists of two equal circles, one of which is attached to the under carriage, by bedding it on the fore axle bed *M*, and the other is fixed beneath the fore transom *D*, the flat surfaces of these circles apply to each other, and the perch bolt, *d*, is in the centre of both; their use is to preserve a steady bearing for the upper carriage to work upon while turning round, so that, in whatever direction the fore carriage may be, the steadiness is always preserved. *O*, the pole, is a long timber, which occasionally is placed in the futchel chaps *NN*, being nicely fitted therein, and is confined by two plates, the one bolted to

them at the bottom in front, and the other at the top, at the back end of the chaps; the security is also assisted by a wooden pin *k*, called a gib, which is placed across the futchels, and in a staple which is in the pole; and an iron pin also goes through the futchels and the poles at the free end; on each side of the pole the horses are stationed, and strapped to a loop at the fore end, called a pole ring; its use is to conduct the fore carriage, and may probably be called a carriage lever. *k*, The pole gib, made flat at the bottom, and rounding at the top, to fit the staple in the pole, which it keeps from sitting up at the fore end; it is nailed on by a loose strap to the futchels, and kept in its place by another strap nailed on the opposite side, which is hitched on a brass or plated button.

We now come to the *iron work* of carriages, of which the articles are extremely numerous, and are manufactured by many different mechanics, such as spring and tyre-smiths, &c. The whole requires to be made of particularly tough metal, and to be fitted with extreme exactness, taking care that each gives its proper support without straining or twisting, and that its substance be adequate to the weight it is meant to carry. The iron-work forms the principal part of the carriage, both for value and use; of course its properties cannot be too much attended to, we shall begin with the springs.

The *springs*, by which riding is made comfortable, require the greatest attention to their properties, otherwise their effect is materially injured. They should be all manufactured of well-tempered steel; the greater the number of plates confined within the hoop the better; and the longer the spring, the more easy and elastic its motion. Those that are the least erect, and of course that incline most to the weight which they carry, and that are also the longest, from the bearing, or stays, have superior advantages. Their forms are various, according to the purpose for which they are designed; and they take their names according to their shape, such as the S, the C, the French horn, the scroll, the worm, the single and double elbow, or grasshopper spring. The springs support the weight at their extremities, by means of hoops and shackles; and their elasticity is from the hoops, at which parts the plates are all made thickest, gradually tapering thinner toward the extremities, and shortening about four inches in each plate, from the hoop where the bearing for the spring is fixed. Those that are placed in an erect form are supported with iron stays, which clip the spring at the hoop. Those that are placed horizontally, are supported from the middle, and play the whole length; and those that are circular, have frequently no stays, but are well secured to the bearings; short light springs that contain few plates, have frequently no hoops, but the plates are confined with a small rivet, and the bolts with which the spring is confined to its bearings. The principle of springs has been thus stated:—To produce motion when the load is fixed to the carriage, it is evident that the whole mass of the load and carriage together must be simultaneously moved; because, where all the particles of the mass are fixed, one particle cannot move till the whole

move. It is well known how much a horse is obliged to strain himself in putting a heavy load in motion; and the violent shocks he has to sustain from the jolting of the carriage, arising from the unbroken impulse of the whole mass coming upon him, are equally notorious. These disadvantages never occur, at least to the hundredth part of the amount, when the load is supported on springs; because, at the first impulse of the animal, the springs partly yield, and that part of the load which they sustain is momentarily left behind, while the carriage moves forward. When his load is therefore suspended in such a way as to allow of its vibrating freely backwards and forwards in the direction of the road, and the horse begins to pull, he has, in the first instance, only to move a part of his load, as the other part is for an instant left behind, and then gradually brought into motion. Hence, it is just in so far as springs allow the load to vibrate, that any advantage is obtained for them in drawing. A considerable advantage would, it is said, be obtained by inserting spiral springs in the traces and harness: but, to return,

Figs. 6, 7, and 8, represent some of the varieties of springs in use for carriages. Fig. 6, called a double spring, is used for a coach or chariot, and has united to it, at the back plate, an additional spring, which turns the reverse way, to carry separate things, such as the budget, or hind platform; it has a double shackle at *g*, one link of which carries the body, and the other the boot, or platform. The reverse spring has only to carry the hind part of the same boot, or platform. The stays and loops marked *a*, *b*, *c*, *d*, *e*, *f*, are for the following purpose; the stay *a* is rivetted within the hoop *b*, and clips at bottom the fore or hind transom, and is there fixed by this bolt *c*, and is supported at the hoop by a stay *d*, which rests on the hind axletree bed, or budget bar; stay *e*, also clips or bolts through the spring at bottom, and clips or unites in a cap with the other; to oppose the pressure, it has a shackle *f*, bolted loosely on the top, for the weight to hang by, and *g* is the shackle for the other spring. Fig. 7 is the scroll spring; this is a peculiar form of spring for ease, and is used to various kinds of carriages; it rests, and is fixed on a long block for phaetons, or on the two bars only for coaches, &c., at the bearings *m m*; the bottom is sometimes turned up in a scroll form, for ornament only, in imitation of the upper part; the brace is hung by a shackle, or placed round the spring, and, passing through a loop *n*, is fixed in a jack *P* at the bottom, which is a little roller, to take up the length of the brace at pleasure, by which the body hangs. Fig. 8 is a spring used to light whiskeys or chairs; it is fixed on the axletree, by a Jew's harp staple, at *o*, which staple is united with the spring hoop and bolts through the axletree; it supports the weight at each end by one or two loops, *p p*, which are fixed at the bottom of the shafts; it is mostly fixed at one end, but has room to play at the other. These springs most generally have only one loop at the hind end, in which it is fixed, and the other end bears on a thin plate, fixed to the bottom of the shafts; sometimes two such springs are combined together for a gig, in a manner as shown in fig. 4.

The *axletrees* of the carriage on which the wheel revolves are of two sorts, the one is made flat, and called a bedded axletree, it being sunk in the timbers; the other is of an octagon form, flat only at the ends, which are bedded. The arms that pass through the wheels should be made perfectly round, and stronger at the shoulder than at the end, which is screwed to receive a nut; through this and the axletree the lynch-pin passes to keep all tight. The nuts are made with a collar at the face, and a temporary collar or washer is driven on to the back of the arms, which forms two shoulders for the wheel to wear against, and helps to preserve the grease from running out. The axletrees, being the principal or only support of the carriage, the greatest attention and care should be given in the selection of good iron, and in the manufacture of the material; taking care that it is well wrought, and of sufficient strength; making it rather stronger than necessary, to avoid risking the life of the passenger by the oversetting of the carriage, which mostly happens when an axletree breaks. By the bend of the axletrees the wheels are regulated to any width at bottom, to suit the bracks of the roads in which they are to run, and are confined in the carriage by means of clips, hoops, and bolts. The shape of the axletree between the shoulders, varies according to its situation, or the form of the timber with which it is united; those axletrees are the most firm that are flat bedded in the timber. The axletree-boxes, frequently called wheel-boxes, are long casings fitted close to the arms of the axletree, and securely fixed in the wheel stocks or naves; they are usually made of wrought sheet iron, of a substance proportioned to the weight of the carriage. Their use is to contain a supply of grease, and to prevent the effects of friction, whereby the wheels are much assisted in their motion. There are many sorts of axletrees and boxes, either for the purpose of containing a longer supply of grease or oil; or to be more durable, or to secure the wheels, and lessen the draught. These are all great advantages, and, though the expense is great, their utility must be more than adequate to it. The common axletree and box are of a conical figure, being strongest at the back or shoulder, and regularly tapering to the end, through which the lynch-pin is fitted; a nut is screwed on the end of the axle to keep the wheel on; the lynch-pin passes through this nut to prevent it from turning round and coming off. This axle and box is most generally used, being simple and cheap in comparison with the others; the box is the only part which wears, and is frequently obliged to be refitted to the arms, otherwise they give the wheel an unsteady motion, and soon exhaust the supply of grease.

Mr. Collinge, of Westminster-road, has for many years past manufactured a patent cylindrical axletree and box, which has very great advantages over the common sort. They have been a considerable time in use, and their advantages have also been fully proved, which principally lie, first, in the length of time they wear; second, in the silent and steady motion they preserve to the wheels; third, the retaining the oil to prosecute a journey of 2000 miles without being once

replenished; and, fourth, they are very durable, and but little subject to be out of order. They have gone through some considerable improvements since their origin, and have met with such encouragement that it has induced other persons to copy them closely.

Fig. 5 is a section of this axletree and box, in which *I* is the axletree arm, made as perfectly cylindrical as possible, and of a peculiarly hard surface; the middle reduced to contain the oil necessary to feed the axletrees at the two bearings *b b*, having a shoulder *c*, against which the wheel-box, *K K*, takes its bearings; the adjoining collar is grooved for a washer to preserve the oil, and prevent noise in its use, with a rim *e e*, on the collar of the axletree, to answer the use of the cuttoo. The end *f* is double screwed, to receive two nuts for securing the wheel; the one screw turns the way of the wheel, the other the reverse, and is meant as an additional security. *K K* is the wheel-box cut through the middle, which is made of a very hard metal, nicely polished, and fitted to the arms, having a recess at the back part for containing a supply of oil. It has two shoulders *c*, the back one fits close to the rim of the collar, which it covers, the fore one projects without the surface of the wheel stock, and is screwed on the inside to receive the screw of the cap *l*, which covers the nut and receives the waste of oil, is mostly made of brass and screwed on, or in the box against the front of the wheel stock. This form of the cap is used to all but the common axletree.

The *wheels* to four-wheel carriages should be formed as nearly of a height as the appearance and construction will permit, and if not required for heavy work, or bad roads, the lighter they are the better. The fixtures from whence the draught is taken, should be placed rather above the centre of the largest wheel, for advantage of draught. The members of a wheel are of three descriptions, viz. the nave, the spokes, and the fellyes; the nave is the stock, made of elm, in which all the spokes are fixed, and in which the axletree or wheel-box is confined to receive the axle-arms. The spokes are straight, made of oak, firmly tenoned in the nave; these are the support of the fellyes or wheel rim. The fellyes, made of ash or beech, form the rim of the wheel, and are divided into short lengths, in the proportion of one to every two spokes; these are fixed on the spokes, and on them iron strakes are nailed. The height of the wheels regulates the number of spokes and fellyes that they are to contain; the larger the circumference of the wheel is, the greater number of spokes is required; they should not be more to any wheel than fifteen inches distance on the fellyes. The usual height of wheels extends to five feet eight inches, and are divided in four proportions, to contain from eight to fourteen spokes, and half that number of fellyes; these are denominated eights, tens, twelves, or fourteens, which are the numbers of spokes in a wheel, or fellyes in a pair. The height which regulates the number for an eight-spoked wheel, should not exceed three feet two inches; for a ten, four feet six inches; for a twelve, five feet four inches; for a fourteen, five feet eight inches: these are the greatest heights for the different numbers of

spokes to each wheel. As the fore wheels of a four-wheel carriage receive more stress than the hind ones, the rule is, when the hind wheels are of that height to require fourteen spokes, the fore ones, if under the necessary height before stated, should have twelve, never allowing the fore wheels to have more than two spokes less than what is needful for the hind ones.

The patent, or bent timber wheel, has the rim of one piece bent to the circle, instead of being put together in short lengths, or fellies, which are hewn to the shape; the strength of the bent timber is preserved, while the other is destroyed; besides, it is hooped with one piece of iron, instead of being shod with strakes, and will often last twice the time in wear that the others will, and has a much lighter and neater appearance, on which account it is often preferred. The mock patent, or hooped wheel, comes very near the others in appearance and use, particularly if made with ash fellies; as the preservation of both lies chiefly in the hoops that the wheels are rimmed with. It is composed partly on the patent plan, and partly on common method, having the timber the same as the strake, and the iron as the patent wheel. The common sort of wheels are preferred by many, on account of their being more easily repaired than the hooped or patent wheel; but, though the repairing of them is more difficult, yet they are much less subject to need it.

Boots and budgets are mostly understood as one article, though so differently called; they are intended for one purpose, which is that of carrying luggage, and are usually fixed on the fore part of the carriage, between the springs; the principal difference lies in this; one is made with a loose cover, and is properly the budget, being made convenient for trunks; these sort of budgets, for travelling carriages, or common post-chaises, are, by far, the most useful, the others are boots, of a trunk form, made more square, and adapted to town carriages, but can be of no other advantage than that of carrying loose hay, horse-cloths, &c. From one or other of these boots, conveniences are sometimes made for the substitute of a coach-box, to save labor to the horse when the carriage is used for post-work, or to preserve an uninterrupted view from within. Boots are frequently used at the fore end of phaetons, and then mostly have the fore springs fixed thereto, by means of carved blocks, which are bolted to their sides; these usually have the step for the entrance to the body fixed or hung. Boots or budgets are sometimes used to the hind part of travelling carriages, but more frequently to the hind parts of phaetons, gigs, or carriages, and are of two sizes less than what are used to coaches or chariots. Platforms, raisers, or blocks, are added to a carriage, either as matter of necessity or appearance; their use is to elevate and support the budget, boot, hind foot-board, and springs; they are generally placed on the side of the carriage, and relieve the inside framings from being obscured by the platforms, as they are lightened and moulded, and give the carriage a more airy appearance.

A handsome *coach-box* is a great ornament to a carriage. Of these there are various sorts now

introduced, to save unnecessary burden to the horse, and fatigue to the driver, which are two very material objects. The objection by many persons to a coach-box, is the obstruction it gives to the view; but they may be so adapted as not materially to affect the sight; and any convenience, however simple, is better than fatiguing both man and horse; but, to carriages used in town, a substantial coach-box is indispensably necessary, as it affords so material an advantage to the driver. The standard coach-box is the most general and simple in use, as it is light, and convenient to remove; it is preferred for those carriages that are alternately used for town and country; these kind of boxes are simply fixed by means of plates, which clip the transom, and are stayed on the hind or boot bar, and fixed with collar-bolts.

The Salisbury boot, though bulky and of a heavy appearance, is by far the most convenient and fashionable coach-box in use; it is boot and coach-box together: and, although it be apparently heavy, it is not more so than the common box or boot, together, as the inside is all a cavity, which is peculiarly convenient for luggage, having a large, flat bottom, which, resting on the framings or blocks, makes it more steady than coach-boxes on the common principles. This sort, however, is not so convenient to remove, and, when taken off, the vacant space must be filled by another kind of budget, such as is usually put on to post-chaises.

We have only room to notice that Mr. Birch, of Great Queen-street, London, obtained, in the year 1807, a patent for an improvement in the construction of the roofs and upper quarters of landaus, barouches, and other carriages, the upper parts of which are made to fall down: which improvement is thus described.

Frame and fix in the top quarter rails to the tops of the standing pillars and slats, and fix the slats to the neck plates; rabbet the under parts of the standing pillars, the top quarter rails and the slats, and board them with thin deals, or any other proper material. Let the crown-pieces or cornice rails be long enough to bevel or mitre into the corners of the top of the standing pillars; and let in the hinges and thimble catches on the top of the crown-pieces and top of the quarter rails. Fix on the hoops-ticks and back and front rails, and board them all up, except the two hoop-sticks which are nearest to the hinges, which may be placed as close as possible, to admit of the head sticking conveniently low. Conceal or let in one or more boxed locks to the centre hoop-sticks, or at least the hoops-ticks which unite the thimble catches, and fix them so as that they may be opened by a key on the inside of the carriage. Stretch strong canvas, or other fit material, and nail it, or otherwise fasten it, both on the inside and the outside of the slats and elbows, and stuff it between with flocks or tow, or other fit material. Likewise stretch and nail on or fasten canvas, or any other proper material, to the top hoop-sticks, on the roof which are nearest the hinges before you put on the leather covering.

The patentee says, that in travelling, a carriage built upon this construction, will carry one or more

imperials on its roof, without interfering with the regular process of opening it, and, when in that situation, will remain without doing the least injury to its upper part. Another advantage is mentioned, viz. that the spring curtains to the landaus remain without being removed, whereas those on the old plan were obliged to be taken down before there was a possibility of opening it.

The practical workman, previously to making the body of a carriage, receives a drawing made on a square canvas; by this the workman makes his patterns, marks out his timber, and saws it according to those patterns. The bottom which is the essential or main timber of the whole, as all the rest principally depend upon it, is of a circular form, four feet long, compassed six inches from the centre, two inches deep, five inches and a half wide in the centre, reduced at the ends to two inches. From the front of the bottom side, at the distant of two feet nine inches, close to the outer circle are framed the standing pillars, the length two feet six inches, one inch and three quarters thick, and two inches and three quarters deep, sweeping outward at the bottom three inches to make the side of the body of a circular form. The front pillars are two feet six inches long, and nine inches wide at the bottom, reduced by an easy sweep to two inches and three quarters at the top, and the whole is two inches and three quarters thick, framed into the front of the bottom side two inches from the point on the outer circle. The corner pillar (two feet six inches long, two inches square, compassed at the bottom five inches, to make a continuation of the sweep of the bottom side, and form a circular quarter), is let into the extreme hind point of the bottom side on the outer circle. To the inside of the bottom side, is framed the front bar three feet long, two inches and a half square, at the distance of two inches from the point, the hind bar three feet four inches long, two inches and a half square, framed in the same manner three inches from the point. On the bottom of the bottom side, is fitted a wooden rocker, which continues from end to end, three inches wide, and four deep, in the centre, reduced to a point at the ends, fixed on with iron bolts, level with the inside of the bottom side. To the rocker the bottom, consisting of deal boards grooved in each other, is nailed and strengthened with iron plates, extending from back to front; the outside elbow is then framed, the length two feet one inch and a quarter thick, and three inches wide, in the middle reduced to an inch and a half at the ends, and turns up at the back part two inches, in an easy sweep, is fixed on the standing pillar nineteen inches from the bottom side. In the hind pillar is framed the rail, three feet five inches long, one inch thick, four inches deep, twelve inches from the bottom side, over which, at the distance of five inches, is framed the sword case rail of the same length, one inch and a half square, compassed one inch, between the standing pillars framed the seat rail, four feet long, two inches square, at the distance of six inches from the bottom side, square with that to the inside of the corner pillars, is screwed the back seat rail. The front latten rail, three feet seven

inches long, three quarters of an inch thick, and one inch and three quarters deep, is framed in the front pillars, distant from the bottom point one foot four inches. The fence rail of the same dimensions ten inches higher. The doors are made with two upright pillars, both of the same dimensions and sweep as the standing pillars, one of which is called the hinge pillar, the other the shutting pillar, in which is framed a batten and fence rail, of the same dimensions and distance as the front two feet long, each compassed one inch on the outside, making a regular sweep with the elbow. In the bottom is framed the door bottom, two feet long, two inches and a half thick, and three inches and a half deep in the centre, compassed to the top of the bottom side.

The body, being now framed, is grooved out to receive the pannels and rounded off for carving; when carved the panneling commences, which is of dry mahogany, planed thin to the grooves, the hind pannel is then cut to the size between the corner pillars; the lower back rail and bottom bar being then compassed by heat to the sweep of the pillar, and fixed to the bottom sides with the pillars, through which two iron bolts are driven and screwed on the inside. The same process is observed with the front quarters, and doors; previous to which, battens are fixed to force the pannels on the sides to a circular form; the pannels are then strengthened on the inside by small pieces of wood an inch and a half square and a quarter of an inch thick, fixed all over them with glue, which is called blocking. The sword case is then fixed in the hind part, by screwing two solid pieces of ash to the corner pillar projecting in the centre eight inches, round which is turned, by means of heat, a thin deal board strengthened inside with glue and canvas; the doors are then hung with brass hinges, fixed in the fore pillars, and fastened, when shut, with a spring lock and dovetail catch to the standing pillars; round the bottom, and upright edges, are screwed brass rabbit plates, to give a good finish, and hide the joints. The pillars are then prepared for the head. In the standing pillar is fixed a strong iron joint, to which is fitted the top pillar, of two feet long and three inches square; in the top of it is fixed the top door case with a joint and hinge, three inches from the standing pillar, full length three feet six inches by three inches in the centre, reduced at both ends to two inches and a quarter; the front pillar of one foot ten inches in length, and two inches and three quarters square, fastened with a double hinge joint, the front of the door case fitted at bottom, on the top of the front pillar, and fixed to that with a strong dovetail lock; the front top rail three feet seven inches long, and two inches and a quarter square, compassed one inch, and the top and bottom is fixed to the front part of the door cases. In the centre of the fore end is fixed the middle front pillar, length four feet, two inches and three quarters wide, and an inch and a quarter thick, in the centre of which pillar, is a lock joint, the upper part fastening with a dovetail plate and bolt. The whole of the pillars are then grooved out for the glasses and blinds; the doors and front outside being now finished, the inside is boarded up with thin deal to receive

the lining and preserve the glasses. The seat is then finished, by fixing boards on the seat rails, from the back pannel one foot eight inches. The hind upper quarter is formed by two compass slats, fixed to a neck-plate in the standing pillar joint, two feet eight inches long, two inches at top, reduced to one inch at bottom and an inch thick; on the top of the hind slat is fixed the back rail, three feet five inches long, by two inches square; swept to correspond with the front rail, on the top of the other slat is fixed a hoop-stick of the same, sweep three feet ten inches by one inch thick and two inches wide. On the top of the door case are fixed three more hoop-sticks of the same dimensions, at the distance of two inches from each other. On the back of the elbow and to the corner pillar is fixed a strong iron prop, which projects six inches from the body; secured inside by an iron stay, as also one on the top of the standing pillar projecting an inch and a quarter, in the ends of which props the main joint is fixed; the lower slat and top rail is then fixed up eighteen inches from the back rail; and the upper slat and hoop-stick fixed ten inches from it; on the elbows made to the sweep are fixed two strong iron plates five inches deep. The steps are then fixed in the centre of the door way in the bottom sides with bolts, width eleven inches, depth, if treble, eleven inches, if single, sixteen inches, cased round with deal to conceal them, when the body is tumbled: the body loops are fixed on the bottom of the rockers, with bolts and nut headed screws, the hind body loops thirteen inches compressed to fancy; the front body loop to the head eighteen inches, from which proceeds a horn six inches long, joined at top to a split stay, which takes the foot board at eighteen inches distance: the other part extending upwards to the bottom of the barouch seat eighteen inches; there is also an iron stay fixed in a socket at the top part in front of the fore pillar, which fastens to the bottom of the seat at the distance of sixteen inches from the body: the width of the seat fifteen inches, and length thirty-one inches, rounded at the hind corners, made of solid board, on the top of which an iron is fixed twelve inches high, level with the outside: the foot board thirty-one inches long, seventeen inches deep, and from the seat to the centre eighteen inches, which finishes the body from the coach-makers' bench.

The body being completed from the coach-makers, it is usual next to cover the sword case with a piece of fine neat's leather prepared for that purpose, and put on wet with paste or white lead to keep it from rising in the hollow part. A very great improvement has lately taken place in covering the top part of coaches, and chariots, by putting the leather on whole, so as to prevent the possibility of wet penetrating, as was frequently the case when put on in separate pieces, and joined on each other by nails, &c. The pannels of the body are painted three or four times with oil color, and several times after with a composition of ground white lead, spruce or brown ochre, turpentine and varnish, and when hard, rubbed to a smooth surface with pumice stones and water. The color, whatever it may be, is laid a sufficient number of times to be solid,

and varnished twice, previous to arms, if any, being put on, afterwards varnished as often as required, being various according to color, &c. &c. The process of painting the carriage is, by giving it a sufficient number of coats to fill up the grain of the wood, rubbing it between each coat with fine sand paper, till it becomes smooth, then ornament it by picking out, and varnish it as often as the nature of the color requires, which never exceeds four times. The inside of the body is then trimmed, the art of which consists in fitting a lining in it composed of cloth, leather lace, &c. in the most ornamental and comfortable manner. The roof, the doors, front, bottom quarters, seat-fall, and the bottom part of the cushions are usually cloth, the upper quarters, top and bottom back, elbows, and top of the cushions morocco. The process is this; first cut out the roof and all the larger parts of the lining: fit the pockets and falls on the front and doors, the pockets and falls are usually bound with broad lace. The morocco part of the lining, with the exception of the cushions and elbows, are made with canvas backs, and bound with narrow lace, stuffed full with curled hair, and tufted with silk or worsted. When the lining is cut out and made up, proceed to line the inside of the sword case with serge, or shalloon of the color of the lining, paste up slips of cloth round the lights, and paste cloth on the recess of the door left to contain the step; nail lace all round the lights, and finish round the same with narrow lace, called parting, fix in the elbows, the bottom, back, bottom quarters, top back, and top quarters, fixing up the roof which is fastened to the hoop-sticks by narrow slips of list nailed to them, and screwed to the roof. The pillars are lined with slips of cloth, bound on each side with lace, through which the hand holders' pass, and are nailed firm to the standing pillars, fix in the front, finishing the sides with the line of lace, which forms part of the front light, fix on the door lining, finishing the edges with a row of parting lace all round. The steps are mostly now very handsomely finished, one side being morocco, and lined with cloth or velvet, welted all round, and the front bound with broad lace. The treads are usually carpet, and, besides a carpet fitted in the bottom, most carriages have spring curtains made of silk, on barrels with silvered ends, the cutting out and fixing up of which, forms a part of the inside trimming. The outside upper part is covered with oiled linen, previous to being covered with very strong-grained neat's leather, which is closed and welted together to fit the roof quarters and back, and, when fixed on, completes the trimmings of the body, the seat: the top iron is usually plated with neat's leather, and japanned, round it a squab or cushion is fitted, the back part of strong leather, the front or inside cloth puckered in full, and welted all round, stuffed and tufted, and fixed in the top iron with straps made up with buckles. Inside the iron the the cushion for the seat is fitted, and a fall is fixed along the front part, a deep valance all round the seat of very strong leather, and a leather from the foot board to the front of the seat, which is called a heel leather. Bodies are, in a greater or less degree, ornamented with beading, of which there are three sorts, plated, brass, and

queen's metal; by the quality of which, buckles, handles, crests, and other ornaments are guided. On the front upper pillars are fixed the lamps, which have been much improved of late years, and are usually made to burn candles; the body and carriage thus prepared are fixed together, by suspending the body loops to the springs of the carriage, by leather braces made of several strips, strongly sewed together with buckles fixed in them; there are also cheek and collar braces, fixed to the upper and lower part of the body, to prevent any violent motion which it would otherwise have.

By law, the wares of coachmakers shall be searched, by persons appointed by the saddler's company. Stat. 1 Jac. I. c. 22. And makers of coaches, chariots, chaises, &c. must take out annual licences from the excise office, and pay a duty for every carriage built by them for sale.

COACHMAN. The driver of a coach, is ordinarily placed on a seat raised before the body. A curious circumstance, connected with this subject, is mentioned in Spanish history. The duke d'Olivarez, having found that a very important secret, mentioned in his coach had been overheard and revealed by his coachman, ordered that the place of the Spanish coachman should be the same with that of the French stage-coachman and our postillion, viz. on the first horse on the left. When lord Macartney presented to one of the Chinese mandarins a very handsome English state-coach for the emperor, the mandarin supposed the elevated coach-box in front was intended for the seat of his majesty, and when it was explained that it was for the driver of the horses, he angrily said, 'that it must be altered, for that the son of heaven would never allow any one to sit above him.'

COACT, v. n. } From *con* and act. Lat.
COACTI^{ON}, n. s. } *coactus*. To act together;
COACTIVE, adj. } to act in concert. Not used.
Compulsion; force, either restraining or impelling. Having the force of restraining or impelling; compulsory; restrictive.

But if I tell how these two did *coact*,
Shall I not lye in publishing a truth. *Shakspeare.*

The Levitical priests, in the old law, never arrogated unto themselves any temporal or *coactive* power.
Raleigh.

It had the passions in perfect subjection; and, though its command over them was persuasive and political, yet it had the force of *coaction* and despotical.
South

COADJUMENT, n. s. from Lat. *con* and *adjumentum*. Mutual assistance.

COADJUTANT, n. s. from Lat. *con* and *adjuto*. Helping; operating.

Thracius *coadjutant*, and the roar

Of fierce Euroclydon. *Philips.*

COADJUTOR, n. s. from Lat. *con* and *adjutor*. A fellow-helper; an assistant; an associate; one engaged in the assistance of another.

I should not succeed in a project whereof I have had no hint from my predecessors, the poets, or their seconds or *coadjutors*, the critics. *Bryden.*

Away the friendly *coadjutor* flies. *Garth's Disp.*

A gownman of a different make,
Whom Pallas, once Venesæ's tutor,
Had fixed on for her *coadjutor*. *Swift.*

In the canon law, one who is empowered or appointed to perform the duties of another.

A bishop that is unprofitable to his diocese ought to be deposed and no *coadjutor* assigned him. *Ayliffe.*

COADJUVANCY, n. s. from Lat. *con* and *adjuvo*. Help; concurrent help; contribution of help; co-operation.

Crystal is a mineral body, in the difference of stones, made of a lentous percolation of earth, drawn from the most pure and limpid juice thereof, owing to the coldness of the earth some concurrence and *coadjuvancy*, but not immediate determination and efficiency.
Broune's Vulgar Errors.

COADUNATE, in botany, an order of plants in the fragmenta methodi naturalis of Linnæus. See **BOTANY**.

COADUNITION, n. s. from Lat. *con, ad, unio*. The conjunction of different substances into one mass.

Bodies seem to have an intrinsic principle of, or corruption from, the *coadunition* of particles endued with contrary qualities. *Hale's Origin of Mankind.*

COAGMENT, v. a. } From Lat. *con* and
COAGMENTATION, n. s. } *agmen*. To congregate or heap together. I have only found the participle in use. Collection, or coagervation, into one mass; union; conjunction.

The third part rests in the well-joining, cementing, and *coagmentation* of words, when it is smooth, gentle, and sweet.
Ben Jonson.

Had the word been *coagmented* from that supposed fortuitous jumble, this hypothesis had been tolerable.
Glanville.

COAGULATE, v. a. & v. n. } Lat. *coagulo*.
COAGULABLE, adj. } To force into
COAGULATION, n. s. } concretions; as
COAGULATIVE, adj. } by affusions of
COAGULATOR, n. s. } some other substance; to turn milk; that which is capable of concretion; to run into concretions, or congelations. The remaining derivatives have the same application, according to their respective parts of speech.

Sal tartre, acaly, and salt peparat,
And combust materes, and *coagulat*.

Roasted in vrath and fire,
And thus oversized with *coagulate* gore. *Shakspeare.*

Vivification ever consisteth in spirits attenuate, which the cold doth congeal and *coagulate*.

Bacon's Natural History.

Spirit of wine commixed with milk, a third part spirit of wine, and two parts milk, *coagulateth* little, but minglcth; and the spirit swims not above. *Bacon.*

Stones that are rich in vitriol, being often drenched with rain-water, the liquor will then extract a fine and transparent substance, *coagulable* into vitriol.

Boyle.

About the third part of the oil olive, which was driven over into the receiver, did there *coagulate* into a whitish body, almost like butter. *Id.*

To manifest the *coagulative* power, we have sometimes in a minute arrested the fluidity of new milk, and turned it into a curdled substance, only by dexterously mingling with it a few drops of good oil of vitriol. *Id.*

As the substance of *coagulations* is not merely saline, nothing dissolves them but what penetrates and relaxes at the same time. *Arbuthnot*

COAGULATION, in chemistry, the act of rendering a fluid body, in some degree, solid, by exposure to cold, or by the addition of some agent by which it is decomposed. Thus the white of eggs, the serum of the blood, &c. are coagulated by the addition of alcohol; milk by mixture with acids; the serum of the blood by exposure to heat, &c. Some writers have called crystallisation by the same name. See **ALBUMEN**.

COAK, a kind of charred fossile coal. For the exciting intense heats, as for the smelting of iron ore, and for operations where the acid and oily particles would be detrimental, as the drying of malt, coals are previously charred, or reduced to coak; that is, they undergo an operation similar to that by which charcoal is made. By this operation coals are deprived of their phlegm, their acid liquor, and part of their fluid oil. Coak, therefore, consists of the two most fixed constituents parts, the heavy oil and the earth, together with the acid concrete salt, which, though volatile, is dissolved by the oil and the earth. It is used in metallurgic works all over Britain, and gives most intense heat. See below.

COAL, *n. s.* & *v. a.* } Sax. col; Lat. *calor*;
COAL-BLACK, *adj.* } heat. A peculiar mineral
COAL-BOX, *n. s.* } fossil fuel; any
COAL-MINE, *n. s.* } thing inflamed or ignited.
COAL-PIT, *n. s.* } Black, of the
COAL-STONE, *n. s.* } darkest species, is the
COAL-WORN, *n. s.* } color of the fossil-coal.
COALERY, *n. s.* } Writing on a light surface,
COALY, *adj.* } with a piece of coal, Camden calls
 coaling: 'he coaled out rhimes upon the wall.' To coal, is to burn, or to convert into coal any substance capable of such transformation by fire.

Sered pokettes, salt peter, and vitriole;
 And divers fires made of wode and cole.

Chaucer's Canterbury Tales.

Insted of cote-armure,—on his harnais,—
 With nayles yelive and bright as any gold,—
 He hadde a beres-skin, *cole-blake* for old. *Id.*

As burning Ætna, from his boiling stew,
 Doth belch out flames, and rocks in pieces broke,
 And ragged ribs of mountains molten new,
 Enwraopt in *coal-black* clouds and althy smoke.

Fæerie Queene.

You are no surer, no,
 Than is the *coal* of fire upon the ice,
 Or hailstones in the sun. *Shakspeare.*
 You have blown this *coal* betwixt my lord and me. *Id.*

Whatsoever doth so alter a body, as it returneth
 not again to that it was, may be called alteratio major;
 as when cheese is made of curds, or coals of wood, or
 bricks of earth. *Bacon.*

Charcoal of roots, *coaled* into great pieces, lasts
 longer than ordinary charcoal. *Id.*

Or *coaly* Tyne, or ancient hallowed Dee. *Milton.*
Coal-black his color, but like jet it shone;
 His legs and flowing tail were white alone. *Dryden.*

Leave a pail of dirty water, a *coal-box*, a bottle, a
 broom, and such other nonsightly things. *Swift.*

Coal-stone flames easily, and burns freely; but
 holds and endures the fire much longer than *coal*. *Woodward.*

Two fine stalactitæ were found hanging from a
 black stone, at a deserted vault in Benwell *coalery*. *Id.*

A leaf of the polypody kind, found in the sinking
 of a *coal-pit*. *Id.*

There is a vast treasure in the old English, from
 whence authors may draw constant supplies; as our
 officers make their surest remits from the *coal-works*
 and the mines. *Felton.*

Springs injure land, that flow from *coal-mines*. *Mortimer.*

Henry III. granted a charter to the town of New-
 castle, in which he gave the inhabitants a license to
 dig *coal*. This is the first mention of *coal* in England.
Hume's History of England.

COAL, among chemists, is synonymous with
 charcoal, and in the new nomenclature is styled
 carbon. See **CHARCOAL** and **CHEMISTRY**, Index.
 In the burning of charcoal one part of it exhales
 without decomposition, and forms a vapor, or an
 invisible gas, called fixed air or carbonic acid.
 This vapor is found to be very pernicious, and
 to affect the animal system in such a manner as
 to occasion death in a very short time. For this
 reason it is dangerous to remain in a close place
 where charcoal, or any other sort of coal, is burnt.
 Persons struck by this vapor are stunned, faint,
 suffer a violent head-ache, and fall down senseless
 and motionless. The best method of recovering
 them is by exposure to the open air, and by
 making them swallow or breathe the steam of
 vinegar.

COAL, in mineralogy, a kind of solid inflam-
 mable substance, supposed to be of a bituminous
 nature, and commonly used for fuel. Of this
 substance there are various species, viz.

COAL, BOVEY, NYLANTHRAX, of a brown or
 brownish-black color, and of a yellow laminar
 texture. According to the German chemists its
 ashes contain a little fixed alkali; but Mr. Mills
 disputes this. It is found in almost all the
 countries of Europe. See **NYLANTHRAX**.

COAL, CANNEL, AMPELITES, of a dull black
 color. It breaks easily in all directions; and,
 if broken transversely, presents a smooth con-
 choidal surface. It burns with a bright lively
 flame, but is very apt to fly in pieces in the fire;
 however, it is said to be entirely deprived of this
 property by immersion in water for some hours
 previous to its being used. It contains a con-
 siderable quantity of petrol in a less condensed
 state than other coals. Its specific gravity is
 about 1270. See **AMPELITES**.

COAL, CULM, called kolin by the Swedes, has
 a greater portion of argillaceous earth and vi-
 triolic acid, with a moderate proportion of petrol.
 It has the same appearance which the lithan-
 thrax, though its texture is more dull: it burns
 with a flame, without being consumed, but
 leaves behind it a slag of the same bulk with the
 original volume of the coal. Kirwan thus de-
 scribes it in the Memoirs of the Stockholm
 Academy: 'its fracture has a rougher section
 than the cannal coal; its specific gravity is from
 1300 to 1370. The best kind affords by distil-
 lation, at first, fixed air; then, an acid liquor;
 afterwards, inflammable air, and light oil of the
 nature of petrol; then, a volatile alkali, and,
 lastly, pitch oil. The residuum is nearly three-

fourths of the whole; and being slowly burnt, affords thirteen per cent. of ashes, which consists mostly of argillaceous earth; and about 300th parts of them are magnetic. It is found in England and among some alluminous ores in Sweden.

COAL, KILKENNY, is the lightest of any; its specific gravity being only about 1400. It contains the largest quantity of asphaltum; burns with less smoke and flame, and more intensely, though more slowly, than the cannel coal. The quantity of earth it contains does not exceed one-twentieth part of its weight; but this kind of coal is frequently mixed with pyrites. It is found in Kilkenny, Ireland. Its quality of burning without smoke, is proverbially used as an encomium on the country.

COAL, PIT. Pit coal is a black, solid, compact, brittle mass, of moderate hardness, lamellated structure, more or less shining, but seldom capable of a good polish; and does not melt when heated. According to Kirwan, it consists of petrol or asphaltum, intimately mixed with a small portion of earth chiefly argillaceous; seldom calcareous; and frequently mixed with pyrites. A red tincture is extracted from it by a spirit of wine, but caustic alkali attacks the bituminous part. 'The varieties of this coal,' says Mr. Magellan, 'are very numerous, according to the different substances with which it is mixed.' See **COAL-MINE**, sect. VIII. 'But in regard to their economical uses, only two kinds are taken notice of by the British legislature, viz. culm, and caking coals. The caking coals, in burning, show an incipient fusion, so that their smallest pieces unite in the fire into one mass; by which means the smallest pieces, and even the mere dust of this kind, are almost equally valuable with the largest pieces. The culm does not fuse or unite in the fiercest fire; so that the small coal, being unfit for domestic purposes, can only be used in burning limestone.' See **CULM**, and **LITHANTHRAX**.

COAL, SLATE, contains such a quantity of argillaceous earth, that it looks like common slate; however it burns by itself with a flame. M. Magellan is of opinion that this is the bituminous schistus, already described under **CLAY**. This schistus is of a dark, bluish, rusty color; when thrown on the fire it burns with a lively flame, and almost as readily as the oily wood of dry olive tree, or lignum vite; emitting the very disagreeable smell of petrol. Such large quarries of it are found near Purbeck in Dorsetshire, that the poorer part of the inhabitants are thence supplied with fuel. From the appearance of this slaty coal, Cronstadt had been induced to suppose that the earth of all kinds of coal is argillaceous, though it is not so easy to distinguish it after being burnt. The pit coals, he says, contain more or less of the vitriolic acid; for which reason the smoke arising from them attacks silver in the same manner as sulphur does, let the coals be ever so free from marcasite, which however, is often imbedded or mixed with them.

COAL, SULPHUREOUS, consists of the former kinds mixed with a very considerable portion of pyrites; whence it is apt to moulder and break when exposed to the air, after which water will

act upon it. It contains yellow spots that look like metal; burns with a sulphureous smell, leaving behind it either slag or sulphureous ashes, or both. Its specific gravity is 1500 or more.

The above are the most considerable varieties of coal commonly known; but we must not imagine that each of them is to be met with in a homogeneous state. On the contrary, the different qualities and proportions of their ingredients make a vast number of other varieties, fit for different purposes, according to the quality and quantity of those they contain. Some of the finer sorts generally run like veins between those of a coarser kind. M. Magellan observed in the fine coal employed in a curious button manufactory at Birmingham, that it produced a much clearer flame than he had ever observed from common coal; yet, on enquiry, he found that the former was picked out from the common coal of the country, through which it ran in veins, and was easily distinguished by the manufacturers. Fourcroy remarks, that this fossil bitumen, when heated in contact with a body in combustion, provided it has a free access of air, kindles the more slowly and with the greater difficulty, in proportion as it is more weighty and compact. When once kindled, it emits a strong and durable heat, and burns for a long time before it is consumed. The matter that is burned, and produces the flame appears very dense, and seems united to some other substance which retards its destruction. On burning it emits a peculiar and strong smell, which is not at all sulphureous when the coal contains no pyrites. When the combustible, oily, and other volatile parts of the coal are dissipated, if the combustion be then stopped, the remainder is reduced to a true charred state, and is called coak. It is well known, says M. Magellan, that the English method of burning pit coal into coak has been a most profitable and happy acquisition for the smelting our ores, and for many other metallurgical and chemical processes in this island. But the ingenious and extensive undertaking of lord Dundonald, by which he turns to very valuable purposes the mines of coal in his and other estates, building ovens of a proper construction for burning pit-coal into coak, and at the same time for collecting, in separate receptacles, the volatile alkali, oil, tar, and pitch, which were generally lost by the usual method, deserves to be noticed, as it affords a very remarkable instance of the great losses to mankind, for want of carefully attending to every result from great processes of art when made on a large scale. These ovens are so contrived, as to admit an under supply of air; and the coals, after being kindled, decompose themselves by a slow but incomplete combustion, which does not destroy the ingredients. The residuum left in the oven proves to be most excellent cinders or coaks; whilst the volatile parts which otherwise would be dissipated in the air, are separated and condensed in reservoirs or receptacles of capacious size, placed at proper distances beyond the reach of fire. M. Faujas de St. Fond, who visited these works in a trip he made to Scotland, undertook to erect a similar kind of oven in France. On subjecting

pit coal, of any kind, to distillation in close vessels, it first yields a phlegm, or watery liquor: then an ethereal or volatile oil; afterwards a volatile alkali; and lastly, a thick and greasy oil; but it is remarkable, that, by rectifying this last oil, a transparent thin and light oil of a straw color is produced, which, being exposed to the air, becomes black like animal oils. From these and similar observations, Messrs. Magellan, Chatal, and others, have inferred, that pit coal is originally a vegetable substance.

COAL, SMALL, is a term sometimes used for a sort of charcoal prepared from the spray and brushwood stripped off from the branches of coppice wood, sometimes bound in barns for that purpose, and sometimes charred without binding, in which case it is called coming together.

Kirwan divides carbonaceous substances into four species, of which the first two contain almost all the varieties of coal. 1. Native mineral carbon, the blonde kofle of Werner, of which the coal found near Kilkenny and the culm of Wales is a species. The former he thus characterises:—Its color is black, and when fresh broken some parts of it generally display a violet color. Its lustre, 4. Metallic. Transparency, 0. Fracture foliated, and the course of the lamellæ variously and confusedly directed. Its fragments, from 2 to 3, often coated with whitish effluviations. Hardness, 7. Specific gravity, 1.526. Will not burn till wholly ignited, and then slowly consumes, without caking, or emitting flame or smoke.

ii. Mineral carbon, impregnated with bitumen, which he subdivides into three families, and thus describes:—

First Family.—Mineral carbon, impregnated with maltha: cannel coal.—First variety.—Composition. This is found chiefly in Lancashire, its proper name is candle-coal, as it burns like a candle; but candles in that shire are called canners. Its color is black. Lustre, common. Transparency, 0. Cross fracture, conchoidal. Fragments, from 2 to 3. Hardness, from 7 to 8. Specific gravity, 1.277 per Watson, or 1.232 by my trials. Does not stain the fingers; easily kindles, and burns with a large bright flame, but of short duration, and then leaves a stony residuum that difficultly burns; does not cake; 240 grains of it heated until all the coal part was consumed, left 7.5 of reddish-brown ashes, mostly argillaceous and siliceous; 100 parts of it contain by my analysis 75 carbon, 21.7 maltha, and 312 of ashes.

Second Variety.—Slaty.—This coal comes to us from Scotland, where it is called splent-coal. Its color is grayish-black. Lustre, 2, common. Transparency, 0. Fracture, partly slaty and partly imperfectly conchoidal. Fragments, 3. Hardness, from 5 to 8. Brittle. Specific gravity, 1.426, by my trials; burns as the former variety, but soon ceases to flame; does not cake, and leaves a stony residuum; 240 grains of it, treated as the former, left 50 grains of reddish-gray ashes; 100 parts of it contain by my analysis 47.6 carbon, 31.0 maltha, and 20.8 of ashes. I even doubt, says this mineralogist, whether it contains so much carbon,

for the best specimens discovered by the smell, when inflamed, a proportion of sulphur.

Second Family.—Mineral carbon, impregnated with asphalt and maltha, in various proportions. Peckhole, Schiefer, kofle of Werner.—Its color is more or less perfectly black, sometimes presenting bright reddish-yellow effluviations, sometimes variegated. Lustre, from 2 to 4, seldom common, mostly greasy or metallic. Transparency 0. Fracture various, mostly foliated, plain, or curved, large or small granularly foliated, sometimes in layers of contrary directions, sometimes promiscuously directed, sometimes presenting small conchoidal distinct concretions, sometimes striated: often in the gross; slaty. Its fragments, 2, often oblong parallelipeds. Hardness, from 4 to 6. Specific gravity, from 1.25 to 1.37, stains the fingers, if moist, or disintegrating, otherwise not. Inflames more slowly, but burns longer than the former family, and cakes more or less, according to the proportion of asphalt. It is often contaminated with lumps, or veins of martial pyrites, sometimes with alum, or intersected with veins of spar. Of this family there are numerous varieties.

First Variety.—From Whitehaven.—Black. Lustre 3, greasy. Fracture plane foliated. Fragments 2. Hardness 6, very brittle. Specific gravity 1.257; 240 grains of it exposed to a heat of 47° for five hours, after flaming a considerable time, caked, and at last left fourteen grains of reddish ashes; 100 parts of it contain by my analysis 56.8 carbon, and 43 of a mixture of asphalt and maltha, in which the asphalt predominates.

Second Variety.—From Wigan.—Black. Lustre 3, greasy, often with bright yellowish effluviations. Fracture foliated, some laminae uniformly, some promiscuously directed, in the gross slaty. Fragments 2. Hardness 6. Specific gravity 1.268, burns more quickly than the former; 382 grains of it exposed in an open crucible, like the former, to a heat of 27°, for four hours, left a residuum of 5.13 grains of reddish-brown ashes.

Third Variety.—From Swansea.—Black. Lustre, 2. Fracture, foliated, but from a contrary direction of the lamellæ seems in part fibrous. Fragments 2. Hardness 5, very brittle. Specific gravity 1.357, burns more slowly than the former varieties; 240 grains of it, treated as above, left eight grains of yellowish-red ashes. One hundred parts of it contain 73.53 of carbon, 23.16 of a mixture of asphalt and maltha, in which the former appears to predominate, and 3.21 of gray ashes.

Fourth Variety.—From Leitrim.—Black. Lustre 3. Fracture, foliated. Fragments, 2. Hardness, 6, very brittle. Specific gravity, 1.351; 240 grains of it exposed to heat, as before, left in three hours a residuum of 12.5 of reddish-gray ashes: one hundred parts of it contain 71.42 of carbon, 23.37 of a mixture of asphalt and maltha, in which the latter appears to predominate, and 5.21 of gray ashes.

Fifth Variety.—From Irvine, in Scotland.—Black. Presents layers in contrary directions, hence often called ribband-coal. Lustre of the alternate layers 3, 2. Fracture small grained

and coarse grained curved foliated. Hardness from 4 to 5. Specific gravity 1.259. Its composition I have not examined. The specific gravity of good bituminous coal never exceeds 1.4, except it contains some quantity of interspersed pyrites.

Third Family.—Carbon bituminated, impregnated with a notable proportion of stony matter. *Spurious Coal.*—I call the proportion of stony matter notable when it exceeds 25 per cent. Its color is grayish-black. Lustre 0.1. Fracture slaty or earthy. Fragments quadrangular, 3. Hardness from 7 to 8. Specific gravity from 1.500 to 1.600. It commonly explodes and bursts when heated; generally found amidst strata of genuine coal. Buffon tells us that the coal of Alaïes is mixed with such a quantity of limestone, that it is often burned for the sole purpose of obtaining lime from it.—2 *Buffon Mineralog.* 8vo. p. 189.

Macquer remarked long ago that nitre detonates with no oily or inflammable matter, until such matter is reduced to coal, and then only in proportion to the carbonaceous matter it contains. Hence it occurred to Mr. Kirwan that, as coals appear in distillation to be for the most part merely compounds of carbon and bitumen, it should follow that, by the decomposition of nitre, the quantity of carbon in a given quantity of every species of coal may be discovered, and the proportion of bitumen inferred. This celebrated chemist accordingly projected on a certain portion of nitre in a state of fusion, successive fragments of various kinds of coal, till the delagration ceased. Coal, when in fine powder, was thrown out of the crucible. The experiments seem to have been judiciously performed, and the results are therefore entitled to as much confidence as the method permits. Lavoisier and Kirwan state, that about thirteen parts of dry wood charcoal decompose 100 of nitre.

100 parts of the best English coal give, of coal, . . . 63 by Mr. Jars.
100 do. 73 Hielm.
100 do. Newcastle do. 58 Dr. Watson.

Kirwan says he copied the result, for Newcastle coal, from Dr. Watson.

Werner, without including the beds of coal found on a sandstone or limestone basis, has ascertained three distinct coal formations.

The first, or oldest formation, he calls the independent coal formation, because the individual depositions of which it is composed, are inde-

pendent of each other, and are not connected. The second is that which occurs in the newest floetz-trap formation; and the third occurs in alluvial land. Werner observes, that a fourth formation might be added, which would comprehend peat and other similar substances; so that we should have a beautiful and uninterrupted series, from the oldest formation to the peat, which is daily forming under the eye. The independent formation contains exclusively coarse coal, foliated coal, cannel coal, slate coal, a kind of pitch coal, and slaty glance coal. The latter was first found in this formation in Arran, Dumfries-shire, Ayrshire and at Westeraigs, by Professor Jameson. The formation in the newest floetz-trap contains distinct pitch coal, columnar coal, and conchoidal glance coal. The alluvial formation contains almost exclusively earth coal and bituminous wood. The first formation, besides coal, contains three rocks which are peculiar to it; these are a conglomerate, which is more or less coarse-grained; a friable sandstone, which is always micaceous; and lastly, slate-clay. But besides these, there occur also beds of harder sandstone, marl, limestone, porphyritic stone, bituminous shale, clay-ironstone; and, as discovered by Professor Jameson, greenstone, amygdaloid, and graphite. The slate-clay is well characterised, by the great variety of vegetable impressions of such plants as flourish in marshes and woods. The smaller plants and reeds occur in casts or impressions always laid in the direction of the strata; but the larger arborescent plants often stand erect, and their stems are filled with the substance of the superincumbent strata, which seems to show that these stems are in their original position. The leaves and stems resemble those of palms and ferns. The central, northern, and western coal-mines of England; the river coal districts of the Forth and the Clyde, and the Ayrshire, and in part the Dumfries-shire coals, belong to this formation, as well as the coals in the northern and western parts of France.

The most valuable and extensive beds of coal which have been found and wrought, are in Great Britain. The general form of our great independent coal-beds, is semi-circular, or semi-elliptical, being the segment of a great basin. The strata have a dip or declination to the horizon of from 1 in 5, to 1 in 20. They are rarely vertical, and seldom perfectly horizontal to any considerable extent. Slips and dislocations of the strata, however, derange more or less the general form.

Professor Jameson has divided this most useful mineral into the following species and sub-species:—

Species 1. Brown coal.

Species 2. Black coal, of which there are four sub-species; slate coal, cannel coal, foliated coal, and coarse coal.

1. Slate coal. Its color is intermediate between velvet-black, and dark grayish-black. It has sometimes a peacock-tail tarnish. It occurs massive, and in columnar and egg-shaped concretions. It has a resinous lustre. Principal fracture slaty; cross fracture imperfect, conchoidal. Harder than gypsum, but softer than calcareous spar. Brittle. Sp. gr. 1.26 to 1.38. It burns longer than cannel coal; cokes more or

less, and leaves a slag. The constituents of the slate coal of Whitehaven, by Kirwan, are 56.3 carbon, with 43.2 mixture of asphalt and maltha, in which the former predominates. This coal is found in vast quantities at Newcastle; in the coal formation which stretches from Bolton, by Altonby and Workington, to Whitehaven. In Scotland, in the river district of Forth and Clyde; at Cannoby, Sanquhar, and Kirconnel, in Dumfriesshire; in Thuringia, Saxony, and many other countries of Germany. It sometimes passes into cannel and foliated coal.

2. Cannel coal. Color between velvet and grayish-black. Massive. Resinous lustre. Fracture flat-conchoidal, or even. Fragments trapezoidal. Hardness as in the preceding sub-species. Brittle. Sp. gr. 1.23 to 1.27. It occurs along with the preceding. It is found near Whitehaven, at Wigan, in Lancashire, Brossely, in Shropshire, near Sheffield; in Scotland, at Gilmerton and Muirkirk, where it is called parret coal. It has been worked on the lathe into drinking vessels, snuff-boxes, &c.

3. Foliated coal. Its color is velvet-black, sometimes with iridescent tarnish. Massive, and in lamellar concretions. Resinous or splendid lustre; uneven fracture; fragments approaching to trapezoidal. Softer than cannel coal; between brittle and sectile. Easily broken. Sp. gr. 1.34 to 1.4. The Whitehaven variety consists, by Kirwan, of 37 carbon, 41.3 bitumen, and 1.7 ashes. It occurs in the coal formations of this and other countries. It is distinguished by its lamellar concretions, splendid lustre, and easy fragility.

4. Coarse coal. Color dark grayish-black, inclining to brownish-black. Massive, and in granular concretions. Glistening lustre. Fracture imperfect, scaly. Fragments indeterminate, angular. Hardness as above. Easily frangible. Sp. gr. 1.454. It occurs in the German coal formations. To the above, Professor Jameson has added soot-coal; which has a dark grayish-black color; is massive; with a dull semi-metallic lustre. Fracture uneven; sometimes earthy. Shining streak; soils; is soft, light, and easily frangible. It burns with a bituminous smell, cakes, and leaves a small quantity of ashes. It occurs along with slate-coal in West-Lothian and the Forth district; in Saxony and Silesia.

Species 3. Glance-coal, of which the Professor gives two sub-species, pitch-coal and glance-coal.

1. Pitch-coal. Color velvet-black. Massive, or in plates and botroidal branches, with a woody texture. Splendent and resinous. Fracture, large perfect conchoidal. Fragments sharp-edged and indeterminate angular; opaque; soft; streak brown-colored. Brittle. Does not soil. Sp. gr. 1.3. It burns with a greenish flame. It occurs along with brown coal in beds, in floetz, trap, and limestone rocks, and in bituminous shale. It is found in the Isles of Sky and Faroe, in Hessa, Bavaria, Bohemia, and Siria. It is used for fuel, and for making vessels and snuff-boxes. It is called black amber in Prussia, and is cut into rosaries and necklaces. It is distinguished by its splendid lustre and conchoidal fracture. It was formerly called jet, from the river Gaga in Lesser Asia.

2. Glance-coal; of which we have four kinds,

conchoidal, slaty, columnar, and fibrous. The conchoidal has an iron-black color, inclining to brown, with sometimes a tempered steel tarnish. Massive and vesicular. Splendent, shining and imperfect metallic lustre. Fracture flat conchoidal; fragments sharp-edged. Hardness as above. Brittle, and easily frangible. In thin pieces it yields a ringing sound. It burns without flame or smell, and leaves a white-colored ash. Its constituents are 96.66 inflammable matter, 2 alumina, and 1.33 silica and iron. It occurs in beds in clay-slate, gray-wacke, and alum-slate; but it is more abundant in secondary rocks, as in coal and trap formations. It occurs in beds in the coal formations of Ayrshire, near Cumnock and Kilmarnock; in the coal district of the Forth; and in Staffordshire. It appears to pass into silty glance-coal.

Slaty glance-coal. Color iron-black. Massive. Lustre shining, and imperfect metallic. Principal fracture slaty; coarse fracture imperfect conchoidal. Fragments trapezoidal. Softer than conchoidal glance-coal. Easily frangible; between sectile and brittle. Sp. gr. 1.50. It burns without flame or odor. It consists, by Dolomieu, of 72.05 carbon, 13.19 silica, 3.22 alumina, 2.47 oxide of iron, and 8 loss. It occurs in beds or veins of different rocks. In Spain in gneiss; in Switzerland in mica-slate and clay-slate; in the trap rock of the Calton-hill, Edinburgh; in the coal formations of the Forth district. It is found also in the floetz districts of Westeraigs, in West Lothian, Dunfermline, Cumnock, Kilmarnock, and Arran; in Brecknock, Caermarthenshire, and Pembrookshire, in England; and at Kilkenny, Ireland; and abundantly in the United States. In this country it is called blind coal.

Columnar glance-coal. Color velvet-black and grayish-black. Massive, disseminated, and in prismatic concretions. Lustre glistening, and imperfect metallic. Fracture conchoidal. Fragments sharp-edged. Opaque. Brittle. Sp. gr. 1.4. It burns without flame or smoke. It forms a bed several feet thick in the coal-field of Sanquhar, in Dumfriesshire; at Saltoats, in Ayrshire, it occurs in beds and in green-stone; in basaltic columnar rows near Cumnock in Ayrshire.

Fibrous coal. Color dark grayish-black. Massive, in thin layers, and in fibrous concretions. Lustre glimmering, or pearly. It soils strongly. It is soft, passing into friable. It burns without flame; but some varieties scarcely yield to the most intense heat. It is met with in the different coal-fields of Great Britain. Its fibrous concretions and silky lustre distinguish it from all the other kinds of coal.

It is not certain that this mineral is wood mineralised. Several of the varieties may be original carbonaceous matter, crystallised in fibrous concretions.

COAL-MINES, BRITISH. It is, generally agreed, that our cannel coal is the lapis ampetites of the Romans; though it seems to have been used by them only for making toys, bracelets, &c. But of that common fuel which we denominate coals, the native Romans were entirely ignorant. It is certain that they are not, as some have imagined, the lapis obsidianus of Pliny, about which there have been great disputes, and of which four statues of elephants were made, and placed in the temple of Concord by Augustus: nor the gagates, or jet, which others, again, have taken for the lapis obsidianus; though the lightness and texture show plainly that it is not either stone or coal. In fact there are no beds of it in the compass of Italy. The great line of that fuel seems to sweep away round the globe, from north-east to south-west, not ranging at a distance even from the south-east parts of our island, as is generally imagined, but actually visiting Brabant and France, and yet avoiding Italy. The primæval Britons appear to have used it; and in the precincts of Manchester particularly, which are furnished with an inexhaustible abundance of it, they could not have long remained unapprised of the useful combustible around them. The currents there frequently bring down fragments of coal from the mountains; and in the long and winding course of them through the parish the Britons would soon mark the shining stones in the channels; and by the aid of accident, or the force of reflection, find out the utility of them. But we can advance still nearer to a certainty. Several pieces of coal were discovered some years ago in the sand under the Roman way to Ribchester, when both were dug up at the construction of a house in Quay-street. The number of pieces, several of them as large as eggs, was not less than forty; and a quantity of slack was dug up with them. These circumstances show the coals to have been lodged on the spot, before the road of the Romans covered it. That ground being in the neighbourhood of Mancunon, the Britons had there deposited a quantity of coals, probably for the use of the garrison, and many of the smaller frag-

ments, and some of the slack, were buried in the sand upon which they were laid. And that the Britons, in general, were acquainted with this fuel, is evident from its appellation amongst us at present, which is not Saxon, but British; and subsists among the Irish in their O-gual, and among the Cornish in their kolan, to this day. The extensive coal-mines, therefore, with which the kingdom of England and the precincts of Manchester are so happily stored, were first noticed by the skill, and first opened by the labor, of the Britons; and some time before the arrival of the Romans among us. And the nearer quarries in the confines of Bradford, Newton, and Manchester, would naturally attract the notice, and invite the enquiries of the Britons, before any others. The current of the Medlock, which washes the sides of them, would bring down specimens of the riches within, lodge many of them about the Castlefield, and allure the Britons successively to a collection of the one and a search after the other. But, for two ages after the discovery, wood continued to compose the general firing of the nation. In 852 a grant was made of some lands by the abbey of Peterborough, under the reservation of certain boons and payments in kind to the monastery; as, one night's entertainment; ten vessels of Welsh, and two of common ale; sixty cart-loads of wood, and twelve of pit coal; where we see the quantity of coal was only one cart-load to five of wood. The latter naturally continued the principal article of our fuel, as long as the forests and thickets presented themselves so readily to the hand; and such it continued till a very late period. The first public notice of the former is mentioned by Mr. Hume to have been in the time of Henry III. who, in the year 1272, granted a charter to the town of Newcastle, giving the inhabitants a licence to dig coals, and the first statute relating to this article was in the 9 Henry V. c. 10; ordering all keels in the port of Newcastle to be measured by commissioners, before carriage of coals, on pain of forfeiture. They were not brought into common use till the reign of Charles I., and were then sold for about 17s. a chaldron.

In some years after the Restoration, there were about 200,000 chaldrons burnt in London; in 1670 about 270,000 chaldrons; and at the Revolution, upwards of 300,000 chaldrons; and at present, above 1,000,000 are annually consumed here. In Scotland there are coals sufficient to supply the consumption, and also to export; but a considerable quantity of English coals are imported, because they are found of a stronger heat, and otherwise better adapted to several manufactures. In Ireland, though they have coal, yet they take annually to the value of £40,000 from England, and £20,000 from Scotland. Maliciously setting fire to coal mines is felony, by stat. 20 Geo. II. c. 32. sect. 6.

COAL-MINES, FOREIGN. There are several other countries in Europe, which possess considerable coal-mines; as France, Liege, Germany, and Sweden: also on the other side of the Atlantic Ocean; in Newfoundland, Cape-Breton, Canada, and some of the states of New England. But in all these countries the coal is of a quality much inferior to the British, and entirely unfit to be used in many manufactures; so that they are obliged to import great quantities from Britain for the use of their manufactures of iron, &c.

The INLAND COAL TRADE, that is, carrying coals from Newcastle, Sunderland, Blith, and other adjacent places in the north of England, as also from the Frith of Forth to London, and the port-towns on the coast all the way, as well as on this side of Newcastle, south, as up the channel as high as Portsmouth west, is an important branch of commerce, and employs abundance of shipping and seamen; in so much that, in a time of urgent necessity, the coalery navigation alone has been able to supply the government with a body of seamen for the royal navy, able to man a considerable fleet at a very short warning, and that without difficulty. The Whitehaven coaleries in Cumberland, belonging to lord Lonsdale, which furnish several counties in Ireland with coals, constantly employ upwards of 2000 seamen; and are a noble nursery for the navy of this kingdom. And not only do the pit coals sufficiently supply all the ports, but, by those ports and the navigable rivers, all the adjacent counties very far inland. In short, coals, though not an exclusive, yet may, with propriety, be styled a peculiar blessing to Britain from their great plenty, their acknowledged excellence, and their being found in such places as are conveniently situated for exportation. Nor is there any danger of the export trade being lessened even by the several duties that have been laid upon them; for the foreign consumption being founded in necessity, with regard to manufactures, and in economy, where they are used for convenience (wood and turf being dearer than coals with the duty), we need be in no fear of the markets declining. There is as little room to be alarmed from an apprehension of their being exhausted, as the present works are capable of supplying us for a long series of years, and there are many other mines ready to be opened when these shall fail. Besides, there are known to be coals in many parts of the three kingdoms, which hitherto there has been no encouragement to work. Besides the value of this com-

modity as a conveniency of life, as an article of commerce, and as giving rise to a nursery of seamen for the increase of the marine, other important advantages deserve to be noticed. Coals are, in many respects, and in a very high degree, useful to the landed interest; not only by raising exceedingly the real value, and of course the purchase, of those lands in which they are found, and those through which it is necessary to pass from the works to the places where they are embarked (which are styled way-leaves, and are set at as high rents as any lands in Britain); but from the general improvements they have occasioned. Very few counties are now better cultivated than Northumberland, and the same effects have been produced, in a greater or less degree, in other places. Thousands of laborious people are employed in and about the mines; thousands more in conveying them to the ports, and on board the ships; to say nothing of those that draw their subsistence from the carriage of them by land to supply families, &c. Great numbers also live in a superior station; as stewards, directors, factors, agents, book-keepers, &c. To these we may add the extraordinary encouragement given to ingenious artists who have invented, and the numerous workmen continually employed about those several curious and costly machines, which, for a variety of purposes in this business, are in continual use, and of course in continual wear: we may join to these the multitudes that obtain their living from the manufactures in which they are employed, and which could not be carried on but by the help and cheapness of coals. Lastly, the produce of coals exported, which amounts to a very considerable sum, besides being profitable to the owners, merchants, and mariners, is so much clear gain to the nation. It might be expected, that a trade so beneficial to individuals, and to the nation in general, and which has been gradually increasing for several centuries past, would have been advanced by this time to very great perfection, and reduced to a regular system. But, in one very essential respect, it is found to be quite otherwise. The art of working coal-mines in the most profitable manner is indeed highly improved, but the principles of the art, that of searching for and discovering coal in any district of country, where it has not yet been found, has never, that we know of, been treated in so systematic a manner, as in the *Encyclopædia Britannica*. We shall lay, therefore, before our readers, the following citation from that useful work:—The terrestrial matters which compose the solid parts of the earth (in coal mines) are disposed in strata, beds, or layers, the under surface of one bearing against or lying upon the upper surface of that below it, which last bears or lies on the next below in the same manner. These strata consist of very different kinds of matters, such as free-stone, lime-stone, metal-stone, whin-stone, coal, &c. as will be particularly specified in the sequel. Some of these strata are of a considerable thickness, being often found from 100 to 200 feet or upwards, nearly of the same kind of matter from the superior to the inferior surface; and others are found of the least thickness imaginable, one inch or less. All these

COAL MINES.

strata are divided or parted from each other laterally, either by their even, smooth, polished surfaces, with very thin lamina of soft or dusty matter betwixt them, called the parting, which renders them easy to separate; or else only by the surfaces closely conjoined to each other, without any visible matter interposed betwixt them; yet the different substance of each stratum is not the least intermixed, though sometimes they adhere so strongly together, that it is very difficult to part or disjoin them: in this last case they are said to have a bad parting. Besides this principal division or parting laterally, there are, in some strata, secondary divisions or parting also laterally, separating or approaching towards a separation of the same stratum, into parts of different thicknesses, nearly parallel to each other; in the same manner as the principal partings divide the different strata from each other; but these secondary ones are not so strong or visible, nor make so effectual a parting, as the principal ones do; and are only met with in such strata as are not of a uniform hardness, texture, or color, from the upper to the under surface. There are other divisions or partings called backs, in almost every stratum, which cross the former lateral ones longitudinally, and cut the whole stratum through its two surfaces into long rhomboidal figures. These again are crossed by others called cutters, running either in an oblique or perpendicular direction to the last mentioned backs, and also cut the stratum through its two surfaces. Both these backs and cutters generally extend from the upper or superior stratum down through several of the lower ones, so that these backs and cutters, together with the lateral partings before-mentioned divide every stratum into innumerable cubic, prismatic, and rhomboidal figures, according to the thickness of the stratum, and the position and number of the backs and cutters. They sometimes have a kind of thin partition of dusty or soft matter in them, and sometimes none, like the first mentioned partings; but the softer kind of strata generally have more backs and cutters than the harder kind, and do not extend through the others.

Let A, B, C, D, E, F, G. plate COAL-MINES, fig. 1, represent the principal partings, or the upper and under surfaces of any stratum; then *a, b, c, d, e, f,* will represent the secondary lateral partings nearly parallel to the principal ones; *g, h, i, k, l, m,* the longitudinal partings called backs; *n, o, p, q, r, s,* the cross partings called cutters, crossing the last mentioned ones either obliquely or perpendicular. In all places where the strata lie regular, they are divided and subdivided in the manner above mentioned; and sometimes in this manner extend through a pretty large district of country: though it is often otherwise; for their regularity is frequently interrupted, and the strata broken and disordered, by sundry chasms, breaches or fissures, which are differently denominated according to their various dimensions, and the matters with which they are filled, viz. dikes, hitches, and troubles.

I. *Dikes* are the largest kinds of fissures. They seem to be nothing but a crack or breach of the solid strata, occasioned by one part of them being broken away and fallen from the other.

They generally run in a straight line for a considerable length, and penetrate from the surface to the greatest depth ever yet tried, in a direction sometimes perpendicular to the horizon, and sometimes obliquely: the same kind of strata are found lying upon each other in the same order, but the whole of them as greatly elevated or depressed on the one side of the dike as on the other. These fissures are sometimes two or three feet wide, and sometimes many fathoms. If the fissure or dike be of any considerable width, it is generally filled with heterogeneous matter, different from that of the solid earth on each side of it. It is sometimes found filled with clay, gravel, or sand; sometimes with a confused mass of different kinds of stone lying edgeways; and at other times with a solid body of free-stone, or even whin-stone. When the fissure is of no great width, as suppose two or three feet only, it is then usually found filled with a confused mixture of the different matters which compose the adjoining strata, consolidated into one mass. If the dike run or stretch north and south, and the same kind of strata are found on the east side of the dike, in a situation with respect to the horizon ten or twenty fathoms lower than on the other side, it is then said to be a dip-dike, or downcast dike of ten or twenty fathoms to the eastward; —or counting from the east, it is then said to be a rise dike or up-cast of so many fathoms westward. If the strata on one side are not much higher or lower with respect to the horizontal line, than those on the other, but only broken off and removed to a certain distance, it is then said to be a dike of so many fathoms thick; and, from the matter contained between the two sides of the fissure or dike, it is denominated a clay-dike, stone-dike, &c.

II. A *hitch* is only a dike or fissure of a smaller degree, by which the strata on one side are not elevated or separated from those on the other side above one fathom. The hitches are denominated in the same manner as dikes, according to the number of feet they elevate or depress the strata. There are dikes (though they are not often met with in the coal countries) whose cavities are filled with spar, the ores of iron, lead, vitriol, or other metallic or mineral matters; and it is pretty well known, that all metallic veins are nothing else than what in the coal countries are called dikes. The strata are generally found lying upon each other in the same order on one side of the dike as on the other, as mentioned above, and nearly of the same thicknesses, appearing to have been originally a continuation of the same regular strata, and the dike only a breach by some later accident, perpendicularly or obliquely down through them, by which one part is removed to a small distance, and depressed to a lower situation than the other. But this is not the only alteration made in the strata by dikes; for generally to a considerable distance on each side of the dike, all the strata are in a kind of shattered condition, very tender, easily pervious to water, and debased greatly in their quality, and their inclination to the horizon often altered.

III. *Troubles* may be denominated dikes of the smallest degree; for they are not a real breach, but only an approach towards it which has not

taken a full effect. The strata are generally altered by a trouble from their regular site to a different position. When the regular course of the strata is nearly level, a trouble will cause a sudden and considerable ascent or descent: where they have, in their regular situation, a certain degree of ascent or descent, a trouble either increases it or alters it to a contrary position: and a trouble has these effects upon the strata in common with dikes, that it greatly debases them from their original quality; the partings are separated; the banks and cutters disjointed, and their regularity disordered: the original cubic and prismatic figures, of which the strata were composed, are broken, and the dislocation filled with heterogeneous matter: and the whole strata are reduced to a softer and more friable state. The strata are seldom, or never, found to lie in a true horizontal situation; but generally have an inclination or descent, called the dip, to some particular part of the horizon. If this inclination be to the eastward, it is called an east dip, and a west rise; and according to the point of the compass to which the dip inclines, it is denominated, and the ascent or rise is to the contrary point. This inclination or dip of the strata is found to hold everywhere. In some places it varies very little from the level; in others very considerably; and in some so much, as to be nearly in a perpendicular direction: but whatever degree of inclination the strata have to the horizon, if not interrupted by dikes, hitches, or troubles, they are always found to lie in the first regular manner mentioned. They generally continue upon one uniform dip until they are broken or disordered by a dike, hitch, or trouble, by which the dip is often altered, sometimes to a different part of the horizon, and often to an opposite point: so that on one side of a dike, hitch, or trouble, if the strata have an east dip, on the other side they may have an east rise, which is a west dip; and, in general, any considerable alteration in the dip is never met with, but what is occasioned by the circumstances last mentioned.

To illustrate what has been said, see fig. 2. where *a b c d*, &c. represents a course of strata lying up on each other having a certain inclination to the horizon. *A B* is a downcast dike, which depresses the strata obliquely to *e f g h*, &c. lying upon each other in the same order, but altered in their inclination to the horizon. *C D* represents a clay or fire-stone dike, where the strata are neither elevated nor depressed, but only broken off and removed to a certain distance. *E F* represents a hitch, which breaks off and depresses the strata only a little, but alters their inclination to the horizon. *G H* represents a trouble, where the strata on one side are not entirely broken off from those on the other, but only in a crushed and irregular situation. As some particular strata are found at some times to increase, and at other times to diminish, in their thickness, while others remain the same, consequently they cannot be all parallel; yet this increase and diminution in their thicknesses come on very gradually. The strata are not found disposed in the earth according to their specific gravities: for we often find strata of very dense matter near the surface: and perhaps a

fifty or even 100 fathoms beneath, we meet with strata of not half the specific gravity of the first. A stratum of iron ore is very often found above one of coal, though the former has twice the gravity of the latter: and, in short, there is such an absolute uncertainty in forming any judgment of the disposition of the strata from their specific gravities, that it cannot in the least be relied upon.

From the foregoing sources we next give an account of the several strata of coal, and of stone and other matters, which are usually connected with coal, and are found to have a particular affinity with it: and shall arrange them into six principal classes, which include all the varieties of strata that occur in all those districts of country both in Scotland and England where coal abounds.

I. The strata of *whin-stone* are the hardest of all others: the angular pieces of it will cut glass: it is of a very coarse texture, and, when broke across the grain, exhibits the appearance of large grains of sand half vitrified; it can scarcely be wrought or broke in pieces by common tools, without the assistance of gunpowder; each stratum is commonly homogeneous in substance and color, and cracked in the rock to a great depth. The most common colors of these strata are black, dark-blue, ash-colored and light-brown. Their thickness in all the coal countries is considerable, from five or six feet to a few inches; and it is only in a few places they are met with of these thicknesses. In the air it decays a little, leaving a brown powder; and in the fire it cracks, and turns reddish-brown. Limestone, especially what is called bastard limestone, is sometimes, though rarely, met with in coaleries. It is well known, but, from its resemblance in hardness and color, is often mistaken for a kind of whin. Sometimes, particularly in hilly countries, the solid matter next the surface is a kind of soft or rotten whin;—but it may be noted, that this is only a mass of heterogeneous matter disposed upon the regular strata; and that beneath this all the strata are generally found in as regular an order as where the heterogeneous matter does not occur.

II. *Post-stone* is a free-stone of the hardest kind, and next to the lime-stone with respect to hardness and solidity. It is of a very fine texture; and, when broken, appears as if composed of the finest sand. It is commonly found in a homogeneous mass, though variegated in color; and, from its hardness, is not liable to injury from being exposed to the weather. Of this kind of stone there are four varieties: the most common is white post, which, in appearance, is like Portland stone, but considerably harder; it is sometimes variegated with streaks or spots of brown, red, or black. Gray post is also very common: it appears like a mixture of fine black and white sand; it is often variegated with brown and black streaks: the last mentioned appear like small clouds composed of particles of coal. Brown or yellow post is often met with of different degrees of color; most commonly of the color of light ochre or yellow sand; it is as hard as the rest, and sometimes variegated with white and black streaks. Red post is generally

of a dull red color; this is but rarely met with; it is often streaked with white or black. All these lie in strata of different thicknesses: but commonly thicker than any other strata whatever: they are separated from each other, and from other kinds of strata, by partings of coal, sand, or soft matter of different colors which are very distinguishable.

III. *Sand-stone* is a free-stone of a coarser texture than post, and not so hard; is so lax as to be easily pervious to water; when broke, is apparently of a coarse sandy substance; is friable and moulders to sand when exposed to the wind and rain; has frequently white shining spangles in it, and pebbles or other small stones enclosed in its mass. Of this there are two kinds commonly met with, distinguished by their colors, gray and brown, which are of different shades, lighter or darker in proportion to the mixture of white in them. It is, most generally, found in strata of considerable thickness, without many secondary partings; and sometimes, though rarely, it is subdivided into layers as thin as the common gray slate. It has generally sandy or soft partings.

IV. *Metal stone* is a stratum, in point of hardness, next to sand-stone; generally solid, compact, of considerable weight, and of an argillaceous substance, containing many nodules of iron ore, and yellow or white pyrite; its partings, or the surfaces of its strata, are hard, polished, and smooth as glass. The most usual color of this stone is black; but there are several other lighter colors, down to a light brown or gray. It lies in strata of various thicknesses, though seldom so thick as the two last mentioned kinds of stone.

V. *Shiver* is a stratum more frequently met with in coaleries than any other. There are many varieties of it, both in hardness and color. The black color is most common; it is called by the miners black shiver, black metal, or bleas. It is softer than metal stone, and in the mine is rather a tough than a hard substance, is not of a solid or compact matter, being easily separable, by the multitude of its partings, &c. into very small parts, and readily absorbing water. The substance of this stratum is an indurated bole, commonly divided into thin laminae of unequal thicknesses, which break into long small pieces when struck with force; and, on examination, they appear to be small irregular rhomboids: each of these small pieces has a polished glassy surface; and, when broke across the grain, appears of a dry leafy, or laminated texture, like exceeding fine clay: it is very friable; feels the touch like an unctuous substance; and dissolves in air or water to a fine pinguid black clay. There are almost constantly found enclosed in its strata lumps or nodules of iron ore; often real beds of the same. Besides black, the brown or dun shiver is frequently met with. Gray shiver is also very common. It lies in strata sometimes of considerable thickness, at other times not exceeding a few feet; they are commonly parted from each other by laminae or spar, coal, or soft matter.

VI. *Coal*. Referring the reader, for the scientific division of coals, to AMPELITES, LI-

THANTIRAN, and the preceding articles, we shall here consider them as distinguishable into three kinds, according to their degrees of inflammability. 1. The least inflammable kinds are Welsh coal, Kilkenny coal in Ireland; and blind or deaf coal, which last is found in many parts of Scotland and England. This coal takes a considerable degree of heat to kindle it, but, when once thoroughly ignited, will burn a long time; it remains in the fire in separate pieces without caking; it produces neither flame nor smoke, and makes no cinder, but burns to a white stony flagg; it makes a hot glowing fire like charcoal or cinders, and emits effluvia of a suffocating nature, which renders it unfit for burning in dwelling-houses, its chief use being among malsters, dyers, &c. for drying their commodities. 2. Open burning coal soon kindles, making a hot pleasant fire, but is soon consumed: it produces both smoke and flame in abundance; but lies open in the fire, and does not cake together so as to form cinders, its surface being burned to ashes before it is thoroughly calcined in the midst; from this it has its name of an open burning coal: it burns to white or brown ashes very light. Of this kind is cannel coal, jet, parrot, splint, and most of the coals in Scotland. 3. Close burning coal kindles very quickly, makes a very hot fire, melts and runs together like bitumen, the very smallest culm making the finest cinders, which, being thoroughly burnt, are porous and light as a pumice stone, and when broke are of a shining lead color; it makes a more durable fire than any other coal, and, finally, burns to brown or reddish colored heavy ashes. Of this kind are the Newcastle and several other of the English coals, and the smithy coals of Scotland. The open burning and the close burning coal mixed together, make a more profitable fire for domestic uses than either of them separate. In all those districts where coal is found there are generally several strata of it; perhaps all the different kinds above mentioned will be found in some, and only one of the kinds in others; yet this one kind may be divided into many different seams or strata, by beds of shiver or other kinds of matter interposing, so as to give it the appearance of so many separate strata. All these strata, with their several varieties, do not lie upon each other in the order in which they are described, nor in any certain or invariable order. Though there be found the same kind of strata in one coalery as in another, yet they may be of very different thicknesses. In some places there are most of the hard kinds, in others most of the softer; and in any one district it rarely happens that all the various kinds are found; for some kinds occur only once or twice, whilst others occur ten or twenty times before we reach the principal stratum of coal.

To explain this, suppose the strata in the pit at A, fig. 3, lie in the order *a, b, c, d*, &c. they may be so much altered in their thicknesses by reason of some of them increasing and others diminishing, at the distance of B, that they may be found there of very different thicknesses; or if they are examined in a pit at D, by reason of its lower situation, and the strata there not being a continuation of those

in the other places, they may be very different both in their order and thicknesses, and yet of the same kinds. Though they be thus found very different in one coalery, or district, from what they are found to be in another, with respect to their thicknesses, and the order in which they lie upon each other, yet we never meet with a stratum of any kind of matter but what belongs to some of those above described. To illustrate how the various strata lie in some places, and how often the same stratum may occur

betwixt the surface and the coal, we shall give the following example. The numbers in the left-hand column refer to the classes of strata before described, to which each belongs. The second column contains the names of the strata; and the four numerical columns to the right hand, express the thickness of each stratum in fathoms, yards, feet, and inches. In the following instance the species of sand-stone only occurs twice, and that of post five times, whilst the shiver occurs no less than nine times.

No.	EXAMPLE.	F.	Y.	FT.	I.
	Soil and gravel	0	1	1	0
	Clay, mixed with loose stones	1	1	0	0
3	Coarse brown sand-stone, with soft partings	3	0	2	6
2	White post, with shivery partings	1	1	0	5
5	Black shiver or bleas, with iron-stone balls	2	0	2	0
6	Coarse splinty coal	0	0	2	6
5	Soft gray shiver	0	1	0	7
2	Brown and gray post, streaked with black	1	0	2	0
5	Black shiver, with beds and balls of iron-stone	0	1	2	6
4	Gray and black metal-stone	0	1	1	9
2	White and brown post	1	1	0	0
5	Black and gray shiver, streaked with white	0	1	0	6
3	Soft gray sand-stone, with shivery partings	0	1	1	0
2	Yellow and white post, with sandy partings	1	0	2	0
5	Black and dun shiver, with iron-stone balls	0	1	2	6
2	White post streaked with black, and black partings	1	0	0	6
5	Gray shiver, with iron-stone balls	0	1	0	9
4	Brown and black metal stone	1	1	2	6
5	Hard slaty black shiver	1	1	0	0
5	Coal, hard and fine splint	0	0	3	6
5	Soft black shiver	0	0	0	3
6	Coal, fine and clear	0	0	3	3
5	Hard black shiver	0	0	1	0
	Total fathoms	25	6	0	0

To apply the foregoing observations to practice: suppose it be required to examine whether there be coal in a piece of ground adjoining to, or in the neighbourhood of, other coaleries. It is proper to be informed, at some of the adjacent coaleries, of the number and kinds of strata; the order in which they lie upon each other; to what point of the horizon, and in what quantity, they dip; if any dikes, ditches, or troubles, and the course they stretch. Having learned these circumstances, search in the ground under examination, where the strata are exposed to examination, and compare these with the other. If they be of the same kinds, and nearly correspond in order and thickness, and by lying in a regular manner, and agree by computation with the dip and rise, it may be safely concluded that coal is there: and the depth of it may be judged from the depth of the coal in the other coalery, below any particular stratum which is visible in this.

II. If the solid strata are not exposed to view, either in the hills or valleys of the ground under examination, then search in the adjoining grounds; and if the same kinds of strata are found there as in the adjacent coalery, and there is reason from the dip and other circumstances, to believe that they stretch through the ground to be ex-

amined, it may be concluded that the coal is there, as well as these other strata. Suppose a coalery is on the side of a hill at A, fig. 3, and you would search for coal at B, on the other side of the hill, but in a much lower situation; by observing the several strata lying above the coal at A, and the point towards which they dip, which is directly towards B (if clear of dikes), you may expect to find the same kind of strata on the other side of the hill, but much lower down. Accordingly if some of the strata are visible in the face of the precipice C, they may be compared with some of those in the pit at A. Or if they are not to be seen there, by searching in the opposite hill, they may perhaps be discovered in the place F; where, if they be found in the manner before mentioned, and there be reason to believe they extend regularly from the first place to this, it is more than probable the coal, as well as these strata, will be found in the intermediate ground.

III. If the ground to be examined lie more to the rise of the coal, as at E, which being supposed to be on a flat, perhaps the solid strata there may be wholly covered by the gravel, clay, &c. of the outward surface lying upon them: in this case, by measuring the horizontal distance and the descent of ground from A to F and computing the

quantity of ascent or rise of the coal in that distance: by comparing these together, it may be judged at what depth the coal will be found there, allowing that it lie regular. Thus, suppose the coal at A eighty yards deep, the distance from A to E 500 yards, and that the coal rises one yard in ten yards of horizontal distance:—

	Yds.
Then, from the depth of the pit	80
Deduct the descent of ground from A to E, suppose	24
	—
This remainder would be the depth, if the coal was level	56
But as the coal rises one in ten feet, then deduct what it rises in 500 yards, which is	50
	—
And the remainder is the depth of the coal at E	6

IV. Suppose that the place at B is 500 yards the contrary way, or to the full dip of the coal at A; if a view of the solid strata cannot be obtained, then, by proceeding in the same manner as before, the depth of the coal at that place may be computed. Thus,

	Yds.
To the depth of the coal at the pit A	80
Add the descent or inclination of the coal in 500 yards, which, as before, is	50
	—
This sum would be the depth, if the ground was level	130
But as the ground descends towards B, deduct the quantity of that, which suppose	80
	—
Remains the depth of coal at B	50

If the place to be examined be neither to the full dip nor full rise, but in some proportion towards either, the same method may be pursued, computing how much the coal rises or dips in a certain distance in that direction. If there is known to be a dike in the workings of the pit at A, which elevates or depresses the strata towards the place under examination, then the quantity of the elevation or depression must be accordingly added to, or deducted from, the computed depth of the coal at that place. Suppose there is an upcast dike of ten fathoms or twenty yards towards B, then deduct twenty from fifty, the depth before computed, there will remain thirty yards or fifteen fathoms for the depth of the coal at B. But it often happens that coal is to be searched for, in a part of the country, at such a distance from all other coaleries, that by reason of the intervention of hills, valleys, unknown dikes, &c., the connexion or relation of the strata with those of any other coalery cannot be traced by the methods last mentioned; in which case a more extensive view must be taken of all circumstances than was necessary in the former; and a few general rules founded on the foregoing observations, and on conclusions drawn from them, will greatly assist in determining sometimes with a great degree of probability, and sometimes with absolute certainty, whether coal be in any particular district of country or not.

V. The proper step to be taken in such a case, is to take a general view of that district of country intended to be searched, in order to judge from the outward appearance or face of the country, which particular part, out of the whole, is the most likely to contain those kinds of strata favorable to the production of coal; and consequently the particular part thus found, is the most advisable to be begun with, in the examination. Though the appearance of the outer surface give no infallible rule to judge of the kinds of strata lying beneath, yet it gives a probable one; for it is generally found, that a chain of mountains or hills rising to a great height, and very steep on the sides, are commonly composed of strata much harder and of different kinds from those before described wherein coal is found to lie, and therefore unfavorable to the production of coal; and these mountainous situations are also more subject to dikes and troubles than the lower grounds: so that if the solid strata composing them gave even favorable symptoms of coal, yet the last circumstance would render the quality bad, and the quantity precarious. And, on the whole, it may be observed, that the mountainous situations are found more favorable to the production of metals than of coal. It is likewise generally found that those districts abounding with valleys, moderately rising hills, and interspersed with plains, sometimes of considerable extent, do more commonly contain coal, and those kinds of strata favorable to its production, than either the mountainous or champaign countries; and a country so situated as this last described, especially if at some considerable distance from the mountains, ought to be the first part appointed for particular examination. Plains and level grounds of great extent, generally situated by the sides of rivers, or betwixt such moderately rising grounds as last described, are also very favorable to the production of coal, if the solid strata, and other circumstances in the higher grounds adjoining, be conformable; for it will scarcely be found, in such a situation, that the strata are favorable in the rising grounds, on both sides of the plain, and not so in the space betwixt them. Though plains be so favorable, in such circumstances, to the production of coal, yet it is often more difficult to be discovered in such a situation, than in that before described; because the clay, soil, and other lax matter, brought off the higher grounds by rains and other accidents, have generally covered the surfaces of such plains to a considerable depth, which prevents the exploration of the solid strata there, unless they be exposed to view by digging, quarrying, or some such operation. That part of the district being fixed upon which abounds with moderate hills and valleys as most suitable for the proposed examination, the first step to be taken is to examine all places where the solid strata are exposed to view (which are called the crops of the strata) as in precipices, hollows, &c. tracing them as accurately and gradually as the circumstances will allow, from the uppermost stratum or highest part of the ground to the very undermost; and, if they appear to be of the kinds before described, it will be proper to note in a memorandum book their different thicknesses; the order in which they lie

upon each other, the point of the horizon to which they dip or incline, and the quantity of that inclination, and whether they lie in a regular state. This should be done in every part of the ground where they can be seen, observing at the same time, that if a stratum can be found in one place which has a connexion with some other in a second place, and if this other has a connexion with another in a third place; &c., then, from these separate connexions, the joint correspondence of the whole may be traced and the strata, which in some places are covered, may be known by their correspondence with those which are exposed to view. If by these means the crops of all the strata cannot be seen (which is often the case), and if no coal be discovered by its crop appearing at the surface; yet if the strata that have been viewed consist of those kinds before described, and are found lying in a regular order, it is sufficiently probable that coal may be in that part of the district, although it be concealed from sight by the surface of earth or other matter.

VI. Therefore, at the same time that the crops of the strata are under examination, it will be proper to take notice of all such springs of water as seem to be of a mineral nature, particularly those known by the name of iron water, which bear a mud or sediment of the color of rust of iron, having a strong astringent taste. Springs of this kind proceed originally from those strata which contain beds or balls of iron ore; but, by reason of the tenacity of the matter of those strata, the water only disengages itself slowly from them, descending into some more porous or open stratum below, where, gathering in a body, it runs out to the surface in small streams or rills. The stratum of coal is the most general reservoir of this water; for the iron-stone being lodged in different kinds of shiver, and the coal commonly connected with some of them, it therefore descends into the coal, where it finds a ready passage through the open backs and cutters. Sometimes, indeed, it finds some other stratum than coal to collect and transmit it to the surface; but the difference is easily distinguishable: for the ochrey matter in the water, when it comes from a stratum of coal, is of a darker rusty color than when it proceeds from any other, and often brings with it particles and small pieces of coal; therefore, wherever these two circumstances concur in a number of these kinds of springs, situated in a direction from each other answerable to the stretch or to the inclination of the strata, it may be certain the water comes off coal, and that the coal lies in a somewhat higher situation than the apertures of the springs. There are other springs also which come off coal, and are not distinguishable from common water, otherwise than by their astringency, and their having a blue scum of an oily or glutinous nature swimming upon the surface of the water. These, in common with the others, bring out particles of coal, more especially in the rainy seasons, when the springs flow with rapidity. When a number of these kinds are situated from each other in the direction of the strata, as above described; or if the water does not run forth as in springs, but only forms a swamp, or an extension of stagnant water be-

neath the turf; in either case, it may be depended upon that this water proceeds from a stratum of coal.

VII. If the stratum of coal is not exposed to view, or cannot be discovered by the first method of searching for the crop, although the appearance of the other strata be very favorable, and afford a strong probability of coal being there; and if the last mentioned method of judging of the particular place where the crop of the coal may lie, by the springs of water issuing from it, should, from the deficiency of those springs or other circumstances, be thought equivocal, and not give a satisfactory indication of the coal; then a further search may be made in all places where the outward surface, or the stratum of clay or earth, is turned up by ploughing, ditching, or digging, particularly in the lower grounds, in hollows, and by the sides of streams. These places should be strictly examined, to see if any pieces of coal be intermixed with the substance of the superior lax strata; if any such be found, and if they be pretty numerous and in detached pieces, of a firm substance, the angles perfect or not much worn, and the texture of the coal distinguishable, it may be concluded, that the stratum of coal to which they originally did belong is at no great distance, but in a situation higher with respect to the horizon; and if there be also found along with the pieces of coal other mineral matter, such as pieces of shiver or freestone, this is a concurrent proof, that it has come only from a small distance. Though the two fore-mentioned methods should only have produced a strong probability, yet if this last mentioned place, where the pieces of coal, &c. are found in the clay, be in a situation lower than the springs; when this circumstance is joined to the other two, it amounts to little less than a moral certainty of the stratum of coal being a very little above the level of the springs. But if, on the contrary, these pieces of coal are found more sparingly interspersed in the superior stratum, and if the angles are much fretted or worn off, and very little of other kinds of mineral matter connected with them; it may then be concluded that they have come from a stratum of coal situated at a greater distance than in the former case; and by a strict search, and an accurate comparison of other circumstances, that particular place may be discovered with as much certainty as the other. After the place is discovered, where the stratum of coal is expected to lie concealed, the next proper step to be taken, is to begin digging a pit or hole there perpendicularly down to find the coal. If the coal has no solid strata above and beneath it, but be found only embodied in the clay or other lax matter, it will not be there of its full thickness, nor so hard and pure as in its perfect state when enclosed betwixt two solid strata, the uppermost called the roof, and the undermost the pavement, of the coal: in such situation therefore it becomes necessary, either to dig a new pit, or to work a mine forward until the stratum of coal be found included betwixt a solid roof and pavement, after which it need not be expected to increase much in its thickness: yet as it goes deeper or farther to the dip, it most likely will improve in its quality; for that part

of the stratum of coal which lies near the surface, or only at a small depth, is often debased by a mixture of earth and sundry other impurities, washed down from the surface, through the backs and cutters, by the rains; whilst the other part of the stratum which lies at a greater depth is preserved pure, by the other solid strata above it intercepting all the mud washed from the surface. The above methods of investigation admit of many different cases, according to the greater or less number of favorable circumstances attending each of the modes of enquiry; and the result accordingly admits every degree of probability, from the most distant, even up to absolute certainty. In some situations, the coal will be discovered by one method alone; in others, by a comparison of certain circumstances attending each method; whilst, in some others, all the circumstances that can be collected only lead to a certain degree of probability. In the last case, where the evidence is only probable, it will be more advisable to proceed in the search by boring a hole through the solid strata, than by digging or sinking a pit, it being both cheaper and more expeditious; and in every case which does not amount to an absolute certainty, this operation is necessary, to ascertain the real existence of the coal in that place. We shall now suppose, that having examined a certain district, situated within a few miles of the sea or some navigable river, that all the circumstances which offer only amount to a probability of the coal being there, and that boring is necessary to ascertain it; we shall therefore describe the operation of boring to the coal. Suppose that the ground A, B, C, D, fig. 4, has been examined, and from the appearance of the strata where they are visible (as at the precipice D, and several other places) they are found to be of those kinds usually connected with coal, and that the point to which they rise is directly west towards A, but the ground being flat and covered to a considerable depth with earth, &c. the strata cannot be viewed in the low grounds; therefore, in this, and all similar situations, the first hole that is bored for a trial for coal should be on the west side of the ground, or to the full rise of the strata as at A, where, boring down through the strata 1, 2, 3, suppose ten fathoms, and not finding coal, it will be better to bore a new hole than to proceed to a great depth in that: therefore, proceeding so far to the eastward as B, where the stratum 1, of the first hole, is computed to be ten or twelve fathoms deep, a second hole may be bored, where boring down through the strata 4, 5, 6, 7, 8, the stratum 1 is met with, but no coal; it would be of no use to bore farther in this hole, as the same strata would be found which were in the hole A: therefore, proceeding again so far to the eastward, as it may be computed the stratum 4 of the second hole will be met with at the depth of ten or twelve fathoms, a new hole may be bored at C; where, boring through the strata 9, 10, 11, 12, the coal is met with at 13, before the hole proceed so deep as the stratum 4, of the former. It is evident, that, by this method of procedure, neither the coal nor any other of the strata can be passed over, as the last hole is bored to that stratum which was nearest the surface in the former hole.

The purposes for which *boring* is used are numerous, and some of them of the utmost importance in coaleries. In coaleries of great extent, although the coal be known to extend through the whole grounds, yet accidental turns, and other alterations in the dip, to which the coal is liable, render the boring of three or more holes necessary, to determine exactly to what point of the horizon it dips or inclines, before any capital operation for the winning of it can be undertaken; because a very small error in this may occasion the loss of a great part of the coal, or at least incur a double expense in recovering it. Suppose A, B, C, D, fig. 5, to be part of an extensive field of coal intended to be won or laid dry by a fire engine; according to the course of the dip in adjoining coaleries, the point C is the place at which the engine should be erected, because the coal dips in direction of the line AC, consequently the level line would be in the direction CD; but this ought not to be trusted to. Admit two holes, 1, 2, be bored to the coal in the direction of the supposed dip, at 200 yards distance from each other, and a third hole, 3, at 200 yards distance from each of them: suppose the coal is found, at the hole 1, to be twenty fathoms deep; at the hole 2 ten fathoms deeper; but at the hole 3 only eight fathoms deeper than at 1. Then to find the true level line and dip of the coal, say, A ten fathoms, the dip from 1 to 2, is to 200 yards the distance, so is eight fathoms, the dip from 1 to 3, to 160 yards, the difference from one, on the line 1 2, to *a*, the point upon a level with the hole 3. Again say, A eight fathoms the dip from 1 to 3, is to 200 yards the distance, so is ten fathoms, the dip from 1 to 2, to 250 yards, the distance from 1, in direction of the line 1, 3, to *b*, the point upon a level with the hole 2. Then let fall the perpendicular 1, *c*, which will be the true direction of the dip of the coal, instead of the supposed line AC, and by drawing ED and DF, parallel to the other lines, the angle D, and no other place, is the deepest part of the coal, and the place where the engine should be erected. If it had been erected at the angle C, the level line would have gone in the direction *ch*, by which means about one-third part of the field of coal would have been below the level of the engine, and perhaps lost, without another engine was erected at D. Boring not only shows the depth at which the coal lies, but its exact thickness; its hardness; its quality, whether close burning or open burning, and whether any foul mixture is in it or not; also the thickness, hardness, and other circumstances, of all the strata bored through; and, from the quantity of water met with in the boring, some judgment may be formed of the size of an engine capable of drawing it, where an engine is necessary. When holes are to be bored for these purposes, they may be fixed (as near as can be guessed) in such a situation from each other, as to suit the places where pits are afterwards to be sunk; by which means most of the expense may be saved, as these pits would otherwise require to be bored, when sinking, to discharge their water into the mine below. There are many other uses to which boring is applied. It is generally practised in England, and is brought

to great perfection; and as the operation is generally entrusted to a man of integrity, who makes it his profession, the accounts given by him of the thickness and other circumstances of the strata, are the most accurate imaginable, and are trusted to with the greatest confidence; for as very few gentlemen choose to take a lease of a new coalery which has not been sufficiently explored by boring, it is necessary the accounts should be faithful, being the only guide to rule the landlord in letting his coal, and the tenant in taking it. The instruments used in boring are very simple. The boring rods are made of iron, from three to four feet long and about one inch and a half square, with a screw at each end by which they are screwed together, and other rods added as the hole increases in depth. The chisel is about eighteen inches long, and two and a half broad at the end, which being screwed on the lower end of the rods, and a piece of timber put through an eye at the upper end, they are prepared for work. The operation is performed by lifting them up a little, and letting them fall again, at the same time turning them a little round: by a continuance of which motions, a round hole is fretted or worn through the hardest strata. When the chisel is blunt it is taken out, and a scooped instrument called a wimble put on in its stead; by which the dust or pulverised matter, which was worn off the stratum in the last operation, is brought up. By this substance, the borers know exactly the nature of the stratum they are boring in; and by any alteration in the working of the rods (which they are sensible of by handling them) they perceive the least variation of the strata. The principal part of the art depends upon keeping the hole clean, and observing every variation of the strata with care and attention. Having, by one or other of the methods above described, ascertained the existence of the coal mine, the next object of consideration is the method of working it.

The most remarkable coal work that we have ever had in this island, was that wrought at Borrowstownness, under the sea. The veins of coal were found to continue under the bed of the sea in this place, and the colliers had the courage to work the vein nearly half way over: there being a mote half a mile from the shore, where there was an entry that went down into the coal-pit, under the sea. This was made into a kind of round key or mote as they call it, built so as to keep out the sea, which flowed there twelve feet. Here the coals were laid, and a ship of that draught of water could lay her side to the mote, and take in the coal. This famous coalery belonged to the earl of Kincardine's family. The fresh water, which sprung from the bottom and sides of the coal-pit, was always drawn out upon the shore by an engine moved by water, that drew it forty fathoms. The coal-pit continued to be wrought many years to the great profit of the owners, and the wonder of all that saw it: but, at last, an unexpected high tide drowned the whole at once; the laborers not having time to escape, perished in it.

It is exceedingly uncommon to meet with a stratum of coal which is naturally dry, or whose

subterranean springs or feeders of water are so very small, as to require no other means than the labor of men to draw off or conduct them away; for it most commonly happens that the stratum of coal, and the other strata adjacent, abound so much in feeders of water, that, before access can be had to the coal, some other methods must be pursued to drain or conduct away these feeders: therefore, after the deepest part of the coal is discovered, the next consideration is of the best method of draining it, or, in the miner's language, *of winning the coal*. If the coal lie in such an elevated situation, that a part of it can be drained by a level brought up from the lower grounds, then that will be the most natural method; but whether it be the most proper or not, depends upon certain circumstances. If the situation of the ground be such that the level would be of a great length, or have to come through very hard strata, and the quantity of coal it would drain, or the profits expected to be produced by that coal, should be inadequate to the expense of carrying it up; in such case some other method of winning might be more proper. Or suppose, in another case, it be found, that a level can be had to a coalery, which will cost £2000, and require five years to bring it up to the coal, and that it will drain thirty acres of coal when completed; yet if it be found that a fire engine, or some other machine, can be erected on that coalery for the same sum of money, in one year, which will drain fifty acres of the same coal, then this last would be a more proper method than the level; because four years' profit would be received by this method before any could come in by the other: and after the thirty acres drained by the level is all wrought, a machine of some kind would nevertheless be necessary to drain the remaining twenty acres: so that erecting a machine at first would be on all accounts the most advisable. Where a level can be driven, in a reasonable time, and at an adequate expense, to drain a sufficient tract of coal, it is then the most eligible method of winning; because the charge of upholding it is generally less than that of upholding fire-engines or other machines. If a level is judged most proper, after every consideration of every necessary circumstance, it may be begun at the place appointed in the manner of an open ditch, about three feet wide, and carried forward until it be about six or seven feet deep from the surface, taking care to secure the bottom and sides by timber-work or building; after which it may be continued in the manner of a mine about three feet wide, and three feet and a half high, through the solid strata, taking care all along to keep the bottom upon a level, and to secure the roof, sides, and bottom, by timber or building, in all places where the strata are not strong enough to support the incumbent weight, or where they are liable to decay by their exposure to the fresh air. If the mine have to go a long way before it reach the coal, it may be necessary to sink a small pit, for the convenience of taking out the stones and rubbish produced in working the mine, as well as to supply fresh air to the workmen; and if the air should afterwards turn damp, then square wooden pipes made of deals closely join

ted, commonly called air boxes, may be fixed in the upper part of the the mine, from the pit-bottom all the way to the end of the mine, which will cause a sufficient circulation of fresh air for the workmen. Perhaps in a great length it will be found proper to sink another or more pits upon the mine, and by proceeding in this manner it may be carried forward until it arrive at the coal; and, after driving a mine in the coal a few yards to one side, the first coal pit may be sunk. If a level is found impracticable, or for particular reasons unadvisable, then a fire engine, or some other machine, will be necessary, which should be fixed on the deepest part of the coal, or at least so far towards the dip as will drain a sufficient extent of coal, to continue for the time intended to work the coalery. See STEAM ENGINE. Whether a fire engine, or any other machine is used, it will be of great advantage to have a partial level brought up to the engine-pit, if the situation of the ground will admit it at a small charge, in order to receive and convey away the water without drawing it so high as to the surface; for if the pit is thirty fathoms deep to the coal, and if there is a partial level, which received the water five fathoms only below the surface the engine by this means would be enabled to draw one-sixth part more water than without it; and if there were any feeders of water in the pit above this level, they might be conveyed into it, where they would be discharged without being drawn by the engine. The engine pit may be from seven to nine feet wide; and whether it be circular, oval, or of any other form, is not very material, provided it be sufficiently strong, though a circular form is most generally approved. If any feeders of water are met within a few fathoms from the surface, it will be proper to make a circular or spiral cutting about one foot deep, and a little hollowed in the bottom round the circumference of the pit, to receive and conduct the water down, without flying over the pit and incommoding the workmen. If the strata are of so tender or friable a nature as not to bear this operation, or if the water leaks through them, then it will be necessary to insert in the forementioned cutting a circular piece of timber called a crib, hollowed in the same manner, to collect the water, and a second may be inserted two or three yards below the first, with a sloping notch down the wall or side of the pit, to convey the water from the former into it; proceeding by some of these methods until the pit is sunk fifteen or twenty fathoms; at which place it will be proper to fix a cistern or reservoir, for the first or upper set of pumps to stand in; for if the pit be thirty fathoms, as supposed, it would be too great a length for the pumps to be all in one set from the bottom to top; therefore if any extraordinary feeders are met with, betwixt fifteen and twenty fathoms deep, it would be best to fix the cistern where it may receive them, and prevent their descending to the bottom; observing that the upper set of pumps be so much larger than the lower one, as the additional feeders may require; or, if there are no additional feeders, it ought then to be a little smaller. After the upper cistern is fixed, the operation may be pursued by the other

set of pumps in much the same manner as has been described, until the pit is sunk to the coal; which being done, it would be proper to sink it six or eight feet deeper, and to work some coal out from the dip side of the pit, to make room for a large quantity of water to collect, without incommoding the coal-pits when the engine is not working.

It would exceed the proper bounds of this article to enumerate all the accidents to which engine pits are liable in sinking; we shall therefore only recite a few which seem important. If a quicksand happen to lie above the solid strata, next the surface, it may be got through by digging the pit of such a wideness at the top (allowing for the natural slope or running of the sand), as to have the proper size of the pit on the uppermost solid stratum; where fixing a wooden frame or tube, as the timber work of the pit, and covering it round on the outside with wrought clay up to the top, the sand may again be thrown into the excavation round the tube and levelled with the surface. If the quicksand should happen to lie at a considerable depth betwixt the clay and solid strata, then a strong tube of timber closely jointed and shod with iron, of such a diameter as the pit will admit, may be let down into it; and by fixing a great weight upon the top, and by working out the sand, it may be made to sink gradually, until it come to the rock or other solid stratum below; and when all the sand is got out, if it be lightly caulked and secured it will be sufficient. It sometimes happens that a stratum of soft matter, lying betwixt two hard solid ones, produces so large a quantity of water as greatly to incommode the operations. In such a case a frame work of plank, strengthened with cribs and closely caulked, will stop back the whole or the greatest part of it, provided the two strata which include it are of a close texture; or let an excavation of about two feet be made in the soft stratum, quite round the circumference of the pit; and let that be filled close up betwixt the hard strata, with pieces of dry fir about ten inches square inserted endways, and afterwards as many wooden wedges driven into them as they can be made to receive; if this be well finished, little or no water will find a passage through it. There is an accident of a very dangerous nature to which all coaleries are liable, and which has ruined several, called a crush, or a fitt. When the pillars of coal are left so small as to yield under the weight of the superior strata; or when the pavement of the coal is so soft as to permit the pillars to sink into it, by the great weight that lies upon them, the solid stratum above the coal breaks and falls in, crushes the pillar to pieces, and closes up a great extent of the workings, or probably the whole coalery. As such an accident seldom comes on suddenly, if it be perceived in the beginning, it may sometimes be stopped by building large pillars of stone amongst the coal pillars: but if it has already made some progress, then the best method is to work away as many of the coal pillars adjoining to the crust as may be sufficient to let the roof fall freely down; and if it makes a breach of the solid strata from the coal up to the surface, it will very

probably prevent the crush from proceeding any farther in that part of the coalery. If the crush begin in the rise part of the coalery, it is more difficult to stop it from proceeding to the dip, than it is to stop it from going to the rise when it begins in a contrary part. It rarely happens that any suffocating damp or foul air is met with in an engine pit: the falling of water, and the working of the pumps, generally causing a sufficient circulation of fresh air. But that kind of combustible vapor, or inflammable air, which will catch fire at the candle is often met with. It proceeds from the partings, backs, and cutters of the solid strata, exhaling from some in an insensible manner, whilst from others it blows with as great impetuosity as a pair of bellows. When this inflammable air is permitted to accumulate, it becomes dangerous by taking fire, and burning or destroying the workmen, and sometimes by its explosion will blow the timber out of the pit, and do considerable damage. If a considerable supply of fresh air is forced down the pit by air boxes and a ventilator, or by dividing the pit into two by a close partition of deals from top to bottom, or by any other means, it will be driven out, or so weakened, that it will be of no dangerous consequence: or, when the inflammable air is very strong, it may be safely carried off by making a close sheathing or lining of thin deals quite round the circumference of the pit, from the top of the solid strata to the bottom, and lengthening it as the pit is sunk, leaving a small vacancy behind the sheathing; when the combustible matter, which exhales from the strata, being confined behind these deals, may be vented by one or two small leaden pipes carried from the sheathing to the surface; so that very little of it can transpire into the area of the pit. If a candle be applied to the orifice of the pipe at the surface, the inflammable air will instantly take fire, and continue burning like an oil lamp until it be extinguished by some external cause. Upon the whole, every method should be used to make the pit as strong in every part, and to keep it as dry as possible, and, whenever any accident happens, it should be as expeditiously and thoroughly repaired as possible, before any other operation be proceeded in, lest an additional one follow, which would more than double the difficulty of repairing it.

Among the most splendid, because most useful, of the modern contributions of science to the business of life, is Sir Humphry Davy's safety lamp, designed to obviate these accidents. Previous to the year 1815 no secure preventative had in fact been invented. The steel wheel striking sparks from flint (called a steel-mill) had been introduced in Cumberland, to light the miners at their work; but this attempt singularly and unfortunately terminated in the destruction of the projector. In the course of his experiments on carburetted hydrogen gas, Sir Humphry found that wire gauze of a certain degree of fineness, interposed between two explosive gases, prevented the kindling of the one from communicating to the other; and hence concluded, that a lamp thus surrounded would not expose the external air to combustion. The result has

been completely successful. We exhibit a diagram of it.

C is the oil cistern: B, a brass rim, around which the wire gauze cylinder is fastened at bottom by a screw; F is the feeder through which the oil is supplied to the lamp; T, the trimmer, a wire which passes through a safe tube, for the purpose of raising and trimming the wick; G, the wire gauze cylinder. The gauze cylinder G is closed at the top by a circular piece of wire gauze; above which is placed a second top, H, fitting on the cylinder as a cap. The circular top of this wire gauze cap is three-fourths of an inch above the top of the wire gauze cylinder; W, W, are thick wires surrounding the cylinder, to preserve it from being crushed or bent; R is a ring to hang up the lamp, or to hold it by. The suture, where the two edges of the piece of wire gauze that forms the cylinder meet, must be well doubled and fastened with wire. If the cylinder be of twilled wire gauze, the wire should be of iron or copper, at least of the thickness of one-fortieth of an inch; if of plain wire gauze, the diameter should not be less than one-sixtieth of an inch. The apertures in a square inch should not be less than 784.

The entire merit of this useful invention is Sir Humphry Davy's: and he has devoted all the powers of his great mind to render it complete. The general size of the lamp is a span, that is, from eight to ten inches high, the wire gauze cylinder being two to two and a half inches in diameter. When choked with coal-dust the wire must be cleaned by means of a brush. Sometimes a lens of glass, or a piece of tin is placed before the light, as a reflector. The light without a reflector is about equal to that of a common miner's candle. Gunpowder, phosphorus, sulphur, and pyrites, applied to the outside of the wire gauze, would produce explosion: but sulphur, to produce this effect, must be applied in a considerable quantity, and blown upon by a current of air. There is clearly little danger of these substances being accidentally applied to the safety-lamp in mines. Should the lamp be placed in a current of explosive gas, and great heat be produced, the radiating or cooling surfaces should be increased, and twilled gauze, or a double or triple fold of wire gauze on one side of the lamp, answers this purpose. But the iron wire gauze receives a strong welding heat, a circumstance which is almost impossible in a coalery, then the iron wire would burn, and the lamp become no longer safe to use.

We copy, in confirmation of Sir H. Davy's claim to this invention, 'Resolutions of a meeting held for considering the fact relative to the discovery of the Lamp of Safety.' The names at-

tached are at once decisive of the fact of the question, as well as of its general importance.

' *Soho Square, Nov. 20th, 1817.*

' 3rd.—That Sir. H. Davy not only discovered, independently of all others, and without any knowledge of the unpublished experiments of the late Mr. Tennant on Flame, the principle of the non-communication of explosions through small apertures, but that he has also the sole merit of having first applied it to the very important purpose of a safety-lamp, which has evidently been imitated in the latest lamps of Mr. George Stephenson.

See the whole document in *Tilloch's Magazine* vol. 50. p. 387.

The first operations, after sinking the engine pit, are the working or *driving* a mine in the coal, and sinking the first coal-pit. The situation of this should be a little to the rise of the engine-pit, that the water which collects there may not obstruct the working of the coals every time the engine stops; and it should not exceed the distance of twenty, thirty, or forty yards; because, when the first mine has to be driven a long way, it becomes both difficult and expensive. If there be not sufficient circulation of fresh air in the mine, it may be supplied by the before described air boxes and a ventilator, until it arrive below the intended coal-pit, when the pit may be bored and sunk to the coal, in the manner before mentioned. After the pit is thus got down to the coal, the next consideration should be of the best method of working it. The most general practice in Scotland is to excavate and take away a part only of the stratum of coal in the first working of the pit, leaving the other part as pillars for supporting the roof: and after the coal is wrought in this manner, to such a distance from the pit as is intended, then these pillars, or so many of them as can be got, are taken out by a second working, and the roof and other solid strata above permitted to fall down and fill up the excavation. The quantity of coal wrought away, and the size of the pillars left in the first working, is proportioned to the hardness and strength of the coal and other strata adjacent, compared with the incumbent weight of the superior strata. The same mode of working is pursued in most parts of England, differing only as the circumstances of the coalery may require: for the English coal, particularly in the northern counties, being of a fine tender texture, and of the close-burning kind, and also the roof and pavement of the coal in general not so strong as in Scotland, they are obliged to leave a larger proportion of coal in the pillars for supporting the roof, during the first time of working; and, in the second working, as many of these pillars are wrought away as can be got with safety. The Scots coal in general being very hard, and of the open burning kind, it is necessary to work

it in such a manner as to produce as many great coals as possible, which is best effected by taking away as high a proportion of the coal as circumstances will allow in the first working; on the contrary, the English coal being very tender cannot possibly be wrought large, nor is it of much importance how small they are, being of so rich a quality; so that a larger proportion may be left in pillars in this coal than could with propriety be done in the other; and, when all circumstances are considered, each method seems well adapted to the different purposes intended. The ancient method of working was, to work away as much of the coal as could be got with safety at one working only; by which means the pillars were left so small as to be crushed by the weight of the superior strata, and entirely lost. As great quantities of coals were lost by this method, it is now generally exploded, and the other adopted in its place; by which a much larger quantity of coal is obtained from the same extent of ground, and at a much less expense in the end. The exact proportion of coal proper to be wrought away, and to be left in pillars at the first working, may be judged of by a comparison of the circumstances before mentioned. If the roof and pavement are both strong, as well as the coal, and the pit about thirty fathoms deep, then two-thirds, or probably three-fourths, may be taken away at the first working, and one-third or one-fourth left in pillars. If both roof and pavement be soft or tender, then a larger proportion must be left in pillars, probably one-third or nearly one-half; and in all cases the hardness or strength of the coal must be considered. The next proper step is to fix upon such dimensions of the pillars to be left, and of the excavations from which the coal is to be taken away, as may produce that proportion.

To form a just idea of which, see a plan of part of a pit's working, fig. 6, supposed to be at the depth of thirty fathoms, and the coal having a moderate rise. A represents the engine-pit; B, the coal-pit; *a a B*, the mine from the former to the latter; *B C*, the first working or excavation made from the coal-pit, commonly called the winning mine or winning headway, nine feet wide; *b b b b*, &c. the workings called rooms, turned off at right angles from the others, of the width of twelve feet; *c c c c*, &c. the workings called throughers or thirlings, nine feet wide, wrought through at right angles from one room to another; *d d d*, &c. the pillars of coal left at the first working for supporting the roof, eighteen feet long and twelve feet broad; *D D*, two large pillars of coal near the pit bottom, fifteen or twenty yards long, and ten or fifteen broad, to support the pit, and prevent its being damaged by the roof falling in; *e e*, the level mine wrought in the coal from the engine-pit bottom, four or five feet wide; *f f*, &c. large pillars of coal left next the level, to secure it from any damage by the roof falling in; *g g*, a dike which depresses the coal, one fathom; *h h*, &c. large pillars and barriers of coal left unwrought, adjoining to the dike where the roof is tender, to prevent its falling down. The coal taken out by the first working in this pit is supposed to be one-third

of the whole: and allowing the rooms twelve feet wide, and the thirlings nine feet wide, then the pillars will require to be twelve feet wide, and eighteen feet long; for, if one pillar be in a certain proportion to its adjoining room and thirling, the whole number of pillars will be in the same proportion to the whole number of rooms and thirlings in the pit.

Suppose *A B C D*, fig. 7, to be a pillar of coal eighteen feet long and twelve feet broad, its area will be 216 square feet; *A C H E*, the adjoining thirling, twelve feet by nine feet, and its area 108 square feet; *B A E F G*, the adjoining room, twenty-seven feet long and twelve feet broad, and its area 324 square feet; which added to 108 gives 432 square feet, or two-thirds wrought, and 216 square feet left, or one third of the whole area *F G H D*. In the prosecution of the workings, the rooms to the right of the winning headway should be opposite to the pillars on the left; and the first, third, and fifth pillar, or the second, fourth, and sixth, adjoining to the said headway, should be of such a length as to overlay the adjoining thirlings; as, in the plan, the pillar 2 overlays the thirlings 1 and 3; and the pillar 4, overlays the thirlings 3 and 5; this will effectually support the roof of the main road *B C*, and will bring the other pillars into their regular order, by which means each pillar will be opposite to two thirlings. Also a large portion of coal should be left in all places which are intended to be kept open after the second working; such as the pit-bottoms, air courses, roads, and water courses, or where the roof is tender, as it generally is near dikes, hitches, and troubles; and if the roof should continue tender for a considerable space, it will perhaps be found proper to leave a few inches of coal adhering to the roof, which, together with a few props of timber fixed under it, may support it effectually for a long time. The level mine *e e*, and the winning headway *B C*, should be wrought forward a considerable length before the other rooms, in order to be drove through any dike that might interpose; otherwise the progress of the workings might probably be stopped a considerable time, waiting until a course of new rooms were procured on the other side of the dike. Suppose the dike *g g*, fig. 6, to depress the coal six feet, or one fathom, and that it rises in the same manner on the under side of the dike as it rises on the upper side; in such a case, the only remedy would be to work or drive a level mine through the strata of stone from the engine level at *e*, over the dike, until it intersect the coal at *i*; and from thence to drive a new level mine in the coal at *i i*, and a new winning headway *i h*. To gain a new set of rooms, and to supply fresh air to this new operation, a small mine might be drove from the room *h*, and a hole sunk down upon the level room *i i*; therefore, if the level mine *e e* was not drove so far forward as to have all these operations completed before the rooms and other workings were intercepted by the dike, the working of the pit might cease until these new places were ready. If there be two or three seams of coal in the same pit, having only a stratum of a few feet thick lying between them,

it is then material to observe that every pillar in the second seam be placed immediately below one in the first, and every pillar in the third seam below one in the second; and in such a situation the upper stratum of coal ought to be first wrought, or else all the three together: for it would be unsafe to work the lower one first, lest the roof should break, and damage those lying above. It sometimes becomes necessary to work the coal lying to the dip of the engine or the level; which coal is, consequently, drowned with water, and must, therefore, be drained by some means before it can be wrought. If the quantity of water proceeding from it be inconsiderable, it may then be drained by small pumps laid upon the pavement of the coal, and wrought by men or horses, to raise the water up to the level of the engine-pit bottom: or if the feeders of water be more considerable, and the situation be suitable, the working rod of these pumps might be connected with those in the engine-pit; by which means the water would be raised up to the level: but if the quantity of water be very great: or if, from other circumstances, these methods may not be applicable, then the engine-pit may be sunk as deep below the coal as may be necessary, and a level stone-mine driven from its bottom to the dip of the strata, until it intersects the stratum of coal, from whence a new level mine might be worked, which would effectually drain it.

Suppose *A B*, fig. 8, to be a section of the engine-pit; *B C*, the coal drained by the engine; *B D*, the coal to the dip of the engine intended to be drained; then, if the engine-pit be sunk deeper to *E*, a stone mine may be wrought in the direction *E D*, until it intersect the coal at *D*, by which the water will have a free passage to the engine, and the coal will be drained. If there be another stratum of coal, lying at such a depth below the first as the engine-pit is intended to be sunk to, the upper steam may in some situations be conveniently drained by driving a mine in the lower seam of coal, from *E* to *F*, and another in the upper one from *B* to *D*: and, by boring a hole from *D* to *F*, the water will descend to *F*, and, filling the mine *E F*, rise up to the engine-pit bottom at *E*, which is upon a level with *D*.

When it is judged necessary to work the pillars, regard must be had to the nature of the roof. If the roof be tender, a narrow room may be wrought, through the pillar, from one end to the other, leaving only a shell of coal on each side for supporting the roof the time of working. Suppose *A B C D*, fig. 7, to be a pillar of coal eighteen feet long and twelve feet broad; if the roof is not strong, the room 1, 2, 3, 4, of eight feet wide, may be wrought up through that pillar, leaving a shell of two feet thick on each side; and, if it can be safely done, a part of these shells may be also wrought away, by working two pla-ces through them as at 5 and 6. Thus very little of the coal will be lost: for two-thirds of the whole being obtained by the first working, and above two-thirds of the pillar by the second working, the loss upon the whole would not exceed one-tenth. But some pillars will not produce so great a proportion, and others cannot be wrought:

at all; so that, upon the whole, there may be about one-eighth, one-seventh, or, in some situations, one-sixth part of the coal lost. If the roof be hard and strong, as much coal may be wrought off each side and each end of the pillar as can be done with safety, leaving only a small piece standing in the middle; and, when very strong, several pillars may be taken entirely out without any loss of coal. In all cases it is proper to begin working those pillars first, which lie farthest from the pit bottom, and to proceed working them regularly away towards the pit; but if there be a great number of pillars to the dip of the pit, it is the safest to work these out, before those to the rise of the pit are begun with.

We shall next advert to some of the various methods of bringing the coals from the rooms and other workings to the pit bottom. Where the stratum of coal is of a sufficient thickness, and has a moderate rise and dip, the coals are most advantageously brought out by horses, who draw out the coals in a tub or basket placed upon a sledge; a horse will thus bring out from 400 to 800 cwt. of coals at one, according to the quantity of the ascent or descent. In some coaleries they have access to the workings by a mine made for them, sloping down from the surface of the earth to the coal; and, where that convenience is wanting, they are bound into a net, and lowered down the pit. If the coal be not of such a height as to admit horses, and has a moderate rise, men are employed to bring out the coals: they usually draw a basket of 400 or 500 cwt. of coals fixed upon a small four-wheeled carriage. There are some situations in which neither horses nor men can be properly used; particularly where the coal has a great degree of descent or where many dikes occur: in such cases the coals are best brought out by women called bearers, who carry them in a kind of basket upon their backs, usually a hundred, or a hundred weight and a half at once. When the coals are brought to the pit bottom, the baskets are then hooked to a chain, and drawn up the pit by a rope to the surface, which is best effected by a machine called a gin, wrought by horses. After the coals are got to the surface they are drawn a small distance from the pit, and laid in separate heaps; the larger coals in one heap, the smaller pieces called chews in another, and the cullin or pan-coal in a separate place.

Foul air is very often troublesome in coaleries. Of this there are two kinds; the black damp or styth, which is of a suffocating nature; and the inflammable or combustible damp. In whatever part of any coalery a constant supply or a circulation of fresh air is wanting, there some of these damps exist, accumulate, and become noxious or fatal; and, wherever there is a good circulation of fresh air, they cannot accumulate, being carried away by the stream of air as fast as they exhale from the strata. Upon these principles are founded the several methods of ventilating a coalery.

Suppose the workings of the pits A and B. fig. 6, to be obnoxious to the inflammable damps; if the communication were open betwixt the two pits, the air which went down the pit A would proceed immediately along the mine *e*, and ascend

out of the pit B; for it naturally takes the nearest direction: so that the air in all the workings would be stagnant, and they would be utterly inaccessible from the accumulation of the combustible damp. To expel this, the air must be made to circulate through all the different rooms by collateral air courses made in this manner: The passage *a* must be closed up by a partition of deals, or by a wall built with bricks or stones to prevent the air passing that way. This building is called a stopping. There must also be stoppings made in the thirlings *l l*, &c. betwixt the pillars *f f*, &c. which will direct the air up the mine *e e*, until it arrive at the innermost thirling 2, which is to be left open for its passage. There must also be stoppings made at the side of the mine *a* at *m m*, and on both sides of the main headway BC at *b b*, &c. then, returning to the innermost thirling 2, proceed to the third row of pillars, and build up the thirlings 2 2, &c. leaving open the thirling 3 for a passage for the air; and, proceeding on to the fifth row of pillars, build up in the same manner the stoppings 3 3, &c. leaving open 4 for an air course: and, by proceeding in this manner to stop up the thirlings or passages in every other row of pillars, the current of fresh air will circulate through and ventilate the whole workings, in the direction pointed to by the small arrows in the plan, clearing away all the damps and noxious vapors that may generate. When it is arrived at C, it is conducted across the main headway, and carried through the other part of the pit's workings in the same manner, until it return through *n n* to the pit B, where it ascends; and, as the rooms advance farther, other stoppings are regularly made. In some of those stoppings, on the sides of the main headway, there must be doors to admit the passage for the bringing out coals from the rooms to the pit, as at 5 5: these doors must be constantly shut except at the time of passing through them. If at any time the circulation of the fresh air is not brisk enough, a large lamp of fire may be placed at the bottom of the pit B, which, by rarefying the air there, will make a quicker circulation.

Most of the large coaleries send their coals to the ships for the coasting trade or exportation; and, as the quantity is generally very large, it would take a greater number of carts than could conveniently be obtained at all times to carry them; besides the considerable expense of that manner of carriage; they therefore generally use waggons, for carrying them along waggon-ways, laid with timber; by which means one horse will draw from two to three tons at a time, when in a cart not above half a ton could be drawn. The first thing to be done in making a *waggon-way* is to level the ground in such a manner as to take off all sudden ascents and descents: to effect which, it is sometimes necessary to cut through hills, and to raise an embankment to carry the road through hollows. The road should be formed about twelve feet wide; and no part should have a greater descent than of one yard perpendicular in ten of a horizontal line, nor a greater ascent than one yard in thirty. After the road is formed pieces of timber, about six feet long, and six inches diameter, called sleepers, are laid

across it, being eighteen or twenty-four inches distant from each other. Upon these sleepers other pieces of timber called rails, of four or five inches square, are laid in a lateral direction four feet distant from each other, for the waggon wheels to run upon; which being firmly pinned to the sleepers, the road may then be filled with gravel and finished. The waggons have four wheels, either made of solid wood, or of cast iron. The body of the carriage is longer and wider at the top than at the bottom; and usually has a kind of trap door at the bottom, which, being loosed, permits the coals to run out without any trouble. The size of a waggon to carry 50 cwt. of coals is as follows: length of the top seven feet, nine inches; breadth five feet; length of the bottom five feet; breadth two feet six inches; perpendicular height four feet three inches. Where the pits are situated at a considerable distance from the harbour, it is necessary to have a store-house near the shipping place, where the coals may be lodged, until the ships are ready to take them in. The waggon-way should be made into the store-house, at such a height from the ground as to permit the coals to run from the waggons down a spout into the vessels; or else to fall down into the store-house. This kind of store-house is well adapted for despatch, and saving expense; for a waggon load of coals may be delivered either into the store-house or vessels instantly with very little trouble; and if the coals were exposed to the effects of the sun and rain, they would doubtless be very greatly injured in their quality.

There is no great difference in the weight of different kinds of coals, the lightest being about 74 lbs. avoirdupois, and the heaviest about 79 lbs. the cubic foot: but the most usual weight is 75 lbs. the foot, which is 18 cwt. and 9 lbs. the cubic yard. If one coal measuring exactly a cubic yard, nearly equal to five bolls, be broken into pieces of a moderate size, it will measure seven coal bolls and a half. If broken very small it will measure nine bolls; which shows, that the proportion of the weight to the measure depends upon the size of the coals; therefore it is evident that accounting by weight is the most equitable method.

We have particular personal knowledge of the general merit of the above observations. But some modern improvements in the draining and working of coal-pits may be added.

A careful survey of the real contents of a supposed field of coal, previous to the commencement of any operations, is a precaution that cannot be too strongly recommended. Situations for a clay-level drift have been presumed upon, long leases taken, and works often erected in utter defiance of common prudence, for want of a little careful use of the methods already described for exploring the ground.

Winning or draining the field is effected by a clay-level drift (where suitable) in the following manner.

Let 1, 2, 3, 4, be the borings of the field designed to be won from the ravine at 4 to the crop of the seams at *a*. A clay-level drift is now constructed, from the ravine, until it enters the seam *S*, by which the strata from 3 to 5 is drained.

A pit is then sunk upon 3, *e*, which works the contents of *S* with great ease to the surface. But in the progress of the work a down-throw slip-dike *δ, δ*, may occur, and depress the seam *S*, as at *f*. The nature and extent of this depression is ascertained by carrying forward a horizontal stone-drift, as to *g*, and dropping a bore-hole; the clay-level drift being then continued until it meet the bore-hole 2. When an up-throw slip-dike is met with, the boring is directed upwards from a horizontal drift, and the clay-level drift continued, in a similar manner.

Coals below the level of the clay-drift are won by a shaft sunk at *e*, and worked as at *h, i*, and *k*, by a steam engine, which lifts the water to the clay-level drift, and it works off with its water by the ravine.

This mode of operation, it will be seen, requires a particular situation in the field: when it is nearly horizontal, as it often is, such a plan cannot be pursued: and no small obstacles are sometimes found in sinking the pits through the springs and quicksands that are penetrated at from thirty to fifty fathoms: in one shaft, a feeder of water has been found to yield 4000 gallons a minute. In such cases, the assistance of the steam engine has been incalculable; but there are obstacles of this kind which even that powerful agent cannot, at least without an extravagant outlay, be made to overcome. The water is in these instances stopped, or dammed back, by what is called tubbing and wedging, accomplished by fixing water-tight cylinders of wood, or cast-iron, within the circumference of the shaft. Such proceedings being attended with great labor and cost, as much use as possible is made of each shaft, and they have been made from nine to sixteen feet in diameter.

Working is accomplished by what is called the narrow and the broad way: the former is that described in the foregoing article. But Mr. Buddle, of Walls' End, has recently brought an improvement of it into such great perfection, that we must here briefly advert to it. It is particularly described by Mr. Griffith, in his *Report on the Leinster District*.

By this mode of working, the mine is divided into a convenient number of portions, or districts, each of which is wrought in its turn, and the roof then suffered to fall in: this, however, is proposed for a measure, and the effect of it qualified by leaving in the abandoned part certain great protecting pillars of coal. In fact, this method is a mechanical calculation on the strength of the roof, judiciously and by degrees applied; but the issue is, that this mode of working will withdraw safely seven-eighths of the contents of a coal field, whereas, ten years ago, not above a half, and sometimes not above a third, could be taken.

By the broad way of working no pillars are left, but the coal is wrought out sometimes for 150 yards of surface at once: this mode is only adapted, however, to pits in which it lies near the surface.

As we are going to press, we find the following return has been made to the Corporation Coal and Corn Committee of the quantities of coal, culm, and cinders, imported into the port of London during the year 1825. It is the first return of the kind ever made, and will give the reader some impression of the quantity of fuel consumed in the metropolis.

QUANTITIES OF COAL IMPORTED IN EACH MONTH OF THE YEAR 1825.

Months.	Ships.	Chaldrons.	Vats.
January	359	79,750	—
February	480	110,136	1
March	606	136,573	3
April	445	100,198	—

COALESCE, *v. n.* } Lat. *coalesco*. To unite
 COALESCE, *n. s.* } in masses by a spon-
 COALITION, *n. s.* } taneous approximation
 to each other. To grow together; to join;
 union in one mass or body; conjunction of separate parts in one whole.

The world's a mass of heterogeneous consistencies, and every part thereof a coalition of distinguishable varieties.

Granville.

In the first coalition of a people, their prospect is not great: they provide laws for their present exigence.

Hale.

'Tis necessary that these squandered atoms should convene and unite into great masses; without such a coalition the chaos must have reigned to all eternity.

Bentley.

When vapours are raised, they hinder not the transparency of the air, being divided into parts too small to cause any reflection in their superficies; but when they begin to coalesce, and constitute globules, these globules become of a convenient size to reflect some colors.

Newton

COANE, among the Greeks, a name given to a peculiar species of tutia or tutty, which was always found in a tubular form. It had its name from *κωνη*, a word used to express a kind of cylindrical tube, into which the melted Brass was received from the furnace, and in which it was suffered to cool. In cooling, it always deposited a sort of recement on the sides of the vessel or tube, which was the tutty called coane.

COANGO, a river of Africa, on the west coast, which, after running through the kingdom of Congo, changes its name to Zaire, and falls into the ocean between Sago and Ango.

COANZA, a large, deep, and rapid river of Africa, which rises far in the interior, and, crossing the kingdom of Angola, falls into the Atlantic Ocean, about lat. 9° 20' S., thirty-six miles south of Loanda the capital of that kingdom. It is navigable for 150 miles, and abounds with a variety of fish. It forms several islands, has some cataracts, and one in particular which bears its name. As for its source, and the length of ground it crosses from east to west before it comes to the Portuguese settlement, they are absolutely unknown, as well as the countries through which it runs. It falls into the Atlantic Ocean, thirty miles north-east of Cape Ledo.

COAPTATION, *n. s.* From *coo* and *apto*, Lat. The adjustment of parts to each other.

In a clock the hand is moved upon the dial, the bell is struck, and the other actions belonging to the engine are performed by virtue of the size, shape, bigness, and coaptation of the several parts.

Boyle.

The same method makes both prose and verse beautiful, which consists in the judicious coaptation and ranging of the words.

Broom.

COARCT, *v. a.* } Lat. *coarcto*. To
 COARCTATE, *v. a.* } straiten, to confine into
 COARCTATION, *n. s.* } a narrow compass; to contract power; to restrain; restraint to a narrow space; restraint of liberty.

The wind finding the room in the form of a trunk, and coarctated therein, forced the stones of the window, like pellets, clean through it.

Bacon.

If a man coarctes himself to the extremity of an art, he must blame and impute it to himself, that he has thus coarcted or straitened himself so far.

Agrippa.

Election is opposed not only to coaction, but also to coarctation, or determination to one.

Bramhall.

Straiten the artery never so much, provided the sides of it do not meet, the vessel will continue to beat, below or beyond the coarctation.

Kay.

COARSE, *adj.* } Lat. *crassus*. Gross; not
 COARSELY, *adv.* } separated from impurities
 COARSENESS, *n. s.* } or baser parts; not delicate; rough; inelegant; unpolished; unfinished

!!

by art or education: not nicely expert; rude; uncivil; harsh in manners; mean; vile; repulsive from a too common vulgarity of address; whatever is uncultivated.

First know the materials whereof the glass is made; then consider what the reason is of the *coarseness* or dearness.

Bacon's Essays.

I feel

Of what *coarse* metal ye are moulded.

Shakespeare.

I'll consort, and a *coarse* perfume

Disgrace the delicacy of a feast. *R. common.*

A *coarse* and useless dunghill weed,

Fixed to one spot, to rot just as it grows. *Outway.*

From this *coarse* mixture of terrestrial parts,

Desire and fear by turns possess their hearts.

Dryden.

The good cannot be too much honored, nor the bad too *coarsely* used.

Id.

Praise of Virgil is against myself, for presuming to copy, in my *coarse* English, his beautiful expressions.

Id.

Be pleased to accept the rudiments of Virgil's poetry, *coarsely* translated, but which yet retains some beauties of the author.

Id.

Friends (pardon the *coarseness* of the illustration) as dogs in couples, should be of the same size.

L'Estrange.

A base wild olive he remains;

The shrub the *coarseness* of the crown retains.

Garth.

Consider the penuriousness of the Hollanders, the *coarseness* of their food and raiment, and their little indulgences of pleasure.

Addison on the War.

Practical rules may be useful to such as are remote from advice, and to *coarse* practitioners, which they are obliged to make use of.

Arbutnot.

'Tis not the *coarser* tie of human law

That binds their peace.

Thomson.

COAST, *n. s.*, *v. n.* & *v. a.* } Lat. *costa*; Fr. }
COASTER, *n. s.* } *coste*. The margin of the land next the sea; the shore. It is not used for the banks of less waters. To coast is, to sail within sight of land; to sail near the shore. A coaster is one who thus sails, and who does so from timidity, or apprehension of danger. Thus, the coast is clear, is a proverbial expression, denoting that the danger is over, or that there is not anything to fear, and the coaster may therefore take leave of the shore.

Stere onys into the *coastes* as well as thou can,
When our shippes be yoom, that we may pass in fere;
Lace on a bonnet or twayn, that we may saile nere,
And when they wer the *coastes* nygh, was noon of them all

That wist what lend it was. *Chaucer's Canterbury Tales.*

Ne did it then deserve a name to have,

Till that the venturous mariner that way

Learning his ships from those white rocks to save,

Which all along the southerne *sea-coast* lay,

Threatening unheedy wreeke and rash decay,

For safety that same his sea-marke made,

And named it Albion; but later day

Finding in it fit ports for fisher's trade,

Gan more the same frequent, and further to invade.

Spenser.

The south-east is found to be better for ripening of trees than the south-west; though the south-west be the hottest *coast*.

Bacon.

Going out, and seeing that the *coast* was clear, *Zeluzane* dismissed *Musidorus*.

Sidney.

Nearchus, the admiral of *Alexander*, not knowing the compass, was fain to *coast* that shore.

Broune's Vulgar Errors.

He sees in English ships the Holland *coast*. *Dryden.*

In our small skiff we must not launch too far;

We here but *coasters*, not discoverers, are. *Id.*

But steer my vessel with a steady hand,

And *coast* along the shore in sight of land.

Id. Virgil.

The royal spy, when now the *coast* was clear,

Sought not the garden, but retired unseen. *Id.*

Some kind of virtue, lodged in some sides of the crystal, inclines and bends the rays towards the *coast*, of unusual refraction; otherwise the rays would not be refracted towards that *coast* rather than any other *coast*, both at their incidence and at their emergence, so as to emerge by a contrary situation of the *coast*.

Newton's Opticks.

The greatest entertainment we found in *coasting* it, were the several prospects of woods, vineyards, meadows, and corn-fields, which lie on the borders of it.

Addison on Italy.

The ancients *coasted* only in their navigation, seldom taking the open sea.

Arbutnot on Coins.

Cold as the crags upon his native *coast*,

His mind as barren, and his heart as hard,

Is he whose head conceived, whose hand prepared

Aught to displace *Athena's* poor remains.

Byron's Child Harold.

COAST, CAPE, or COAST CASTLE, CAPE, the chief British settlement on the gold coast of Guinea in Africa. The name is a corruption of Cabo Corso, the ancient Portuguese appellation. This cape is formed by an angular point washed on the south and east by the sea, on which stands the English fort. Here the Portuguese settled in 1610, and built the citadel upon a large rock that projects into the sea. A few years afterwards they were dislodged by the Dutch, to whom this place is principally indebted for its strength. In 1661 it was demolished by Admiral Holmes, and in 1665 the famous Dutch Admiral De Ruyter was ordered by the States to revenge the insults of the English. With a squadron of thirteen men of war, he attacked all the English settlements along the coast, ruined the factories, and took, burnt, and sunk, all the shipping of the English Company; however, after all his efforts, he was baffled in his attempts on Cape Coast. By the treaty of Breda it was confirmed to the English, and the king granted a new charter in 1672: on which the Company applied all their attention to the fortifying and rendering it commodious. The fort is considerably strengthened with high and thick walls, especially on the land side, flanked with four bastions and ten pieces of cannon; but it is too near the town, and even commanded by some of the houses. There are apartments in it for the governor, besides a chapel, and accommodations for different workmen and artificers. The houses in the town are built in a square form, mostly of clay, but the whole appearance very irregular and dirty. It is supposed to contain about 8000 people. The surrounding country was formerly very woody, but some improvement has taken place by the opening of roads, the laying out and planting of private grounds, the erection of mansions, &c. With all the workmen connected with this establishment, the garrison could hardly be raised to 100 men, a force very inadequate to

the importance of the place. It is situated in about 3° W. long., and 5° 15' N. lat.

COASTING, in navigation, the act of making a progress along the sea coast of any country. The principal requisites for this part of navigation are, the knowledge of the time and direction of the tide; of the reigning winds; of the roads and havens; and of the different depths of water, and qualities of the ground.

COASTING PILOT, a pilot who by long experience has become sufficiently acquainted with the nature of any particular coast, and of the requisites mentioned above, to conduct a ship or fleet from one part of it to another.

COAT, *n. s.* & *v. a.* *χρῶν*; Fr. *cotte*. An upper garment, belonging generally to the male sex; the outside covering of animals; but extending to any integument, tunic, or covering; to whatever is placed in the exterior to preserve it either from decay or from cold, from accident and from injury. To coat is not merely to put on the outward garment, but it is to cover, to invest, to overspread. That, on which armorial ensigns are portrayed, is called a coat, probably because these ensigns were originally affixed to the coat, or outward apparel. Coat likewise is used to distinguish the habit or vesture, as demonstrative of office.

He was armed with a *coat* of mail, and the weight of the *coat* was five thousand shekels of brass.

1 *Samuel*.

The *coat* of many colors they brought to their father, and said, this have we found: know now whether it be thy son's *coat* or no.

Genesis.

A white *cote*, and a blew hode, wered he.

Chaucer's Canterbury Tales.

Ther maist thou see devising of harness
So uncouth and so riche, and wrought so wele
Of goldsmithery, of bron'ing, and of stele:
The sheldes brighte testeres and trappures,
Gold-hewen helmes, hauberkes, *cote*-amures. *Id.*

The herald of love's mighty king,
In whose *coat* armour richly are displayed
All sorts of flowers the which on earth do spring.

Spenser.

Cropped are the flower-de-luces in your arms;
Of England's *coat* one half is cut away.

Shakspeare. Henry VI.

He clad

Their nakedness with skins of beasts; or slain,
Or, as the snake, with youthful *coat* repaid;
And thought not much to clothe his enemies.

Milton

Men of his *coat* should be minding their prayers,
And not among ladies, to give themselves airs. *Swift*.
The eye is defended with four *coats*, or skins.

Peacham.

The optick nerves have their medullary parts, terminating in the brain, their teguments terminating in the *coats* of the eye. *Derham's Physico-Theology*.

At each trumpet was a banner bound,
Which, waving in the wind, displayed at large
Their master's *coat* of arms and knightly charge.

Dryden.

Amber is a nodule, invested with a *coat*, called rock-amber. *Woodward on Fossils*.

The finny brood their wonted haunts forsake,
Float in the sun, and skim along the lake,
With frequent leap they range the shallow streams,
Their silver *coats* reflect the dazzling beams. *Gay*.

How his eyes languish! how his thoughts add,
That painted *coat* which Joseph never wore.

Young's Love of Fame

You have given us milk

In luscious streams, and lent us your own *coat*
Against the winter's cold. *Thomson's Spring*.

COAT OF ARMS, in heraldry, a habit worn by the ancient knights over their arms both in war and tournaments, and still borne by heralds at arms. It was a kind of fur coat, reaching as low as the navel, open at the sides, with short sleeves, sometimes furred with ermine and hair, upon which were applied the armories of the knights embroidered in gold and silver, and enamelled with beaten tin, colored black, green, red, and blue; whence the rule never to apply color on color, nor metal on metal.

We insert a wood-cut of the coat of the earl of Chatham, as borne at his funeral.

The coats of arms were frequently open, and diversified with bands and fillets of several colors, alternately placed, as we still see cloths scarleted, watered, &c. Hence they were called devises, as being divided, and composed of several pieces sewed together; whence the words false, pale, chevron, bend, cross, saltire, loz-enge, &c. which have since become honorable pieces, or ordinaries of the shield. Coats of arms and banners were never allowed to be worn by any but knights and ancient nobles.

COAT OF MAIL, a kind of armour made in the form of a shirt; consisting of iron rings woven together netways. See MAIL.

COATING OF PHIALS, PANES OF GLASS, &c., among electricians, is usually performed by covering the outside of the phial with tinfoil, brass or gold leaf, &c. and filling its inside with loose pieces of brass leaf, by which means it becomes capable of being charged. See ELECTRICITY.

COATZACUALCO, a navigable river of North America, in Mexico, which falls into the Gulf of Mexico near Onohualco.

COAX, *v. a.* } *Tent. hesen.* To wheedle,
COAXER. n. s. } to flatter, to humo.; to seduce by low arts.

The nurse had changed her note, she was muzzling and coaxing the child; that's a good dear says she. *M. Stranjo*.

I coax! I wheedle! I'm above it.

Farquhar's Recruiting Officer.

COBALT, *n. s.* A marcasite frequent in Saxony.

Cobalt is plentifully impregnated with arsenick, contains copper and some silver. Being sublimed, the fiores are of a blue color: these, German mineralogists call *zaffir*. *Woodward*.

Cobalt is a dense, compact, and ponderous mineral, very bright and shining, and much resembling some of the antimonial ores. It is found in Germany, Saxony, Bohemia, and England; but ours is a poor kind. From *cobalt* are produced the three sorts of arsenick, white, yellow, and red; as also *zaffir* and smalt.

Hill on Fossils.

112

COBALT, a mineral of a gray color, classed with the semi-metals. It nearly resembles fine hardened steel, and its specific gravity is above 8. It is as difficult of fusion as copper, and, when purified, slowly yields to iron itself in this respect. It is susceptible of magnetism, but in a weaker degree than either steel or nickel. Cobalt, when calcined along with the calx of arsenic in a gentle heat, assumes a red color. The same is naturally produced, by way of efflorescence, and is then called the bloom or flowers of cobalt. It does not mix with mercury by any means hitherto known, nor will it form any union with bismuth without the addition of some medium. It is easily soluble in spirit of nitre, and the solution, either in this or any other acid, is of a red color; and it is observable that the color of the acid solutions of this substance, instead of fading by dilution with water, become more vivid. Cronstätt makes mention of native cobalt; but other mineralogists assure us that it has never been found perfectly pure in the bowels of the earth. That called the gray cobalt ore approaches nearest to the purity of the native metal, but always contains some quantity of arsenic and iron. It is found in Sweden, Saxony, Norway, and England, particularly in the Mendip hills in Somersetshire and in Cornwall, where it has been dug up in large quantities. Here it is sometimes found in conjunction with bismuth and sometimes without it, resembling very much in appearance the Saxon ores of Schöneberg in misnia. An arsenicated gray cobalt ore has also been found at Chateaudun, in France. This kind of ore is solid, heavy, and compact, sometimes dull and sometimes of a bright appearance, crystallised frequently in a tessular and sometimes in a dendritical form; being generally hard enough to strike fire with steel, when an arsenical smell is perceived. The most common ore of cobalt is that called the black or vitreous ore, and *Kobaltmullererschlacken* (cobalt) by the Germans. It is found in a loose powdery form, sometimes resembling lamp-black, sometimes of a gray color, in which state it is called cobalt ochre; but when in scoriiform half-vitrified masses it obtains the name of vitreous or glassy ore. It is frequently embodied in stones or sands of a black color; sometimes it is contained in argillaceous earths of a blue or green color. Talk, chalk, and gypsum, impregnated with it, are called by the same name; and, by some, speiss-cobalt. Cobalt mineralised by the arsenical acid, is found either loose and pure, or mixed with chalk or gypsum, or intermixed and crystallised in tetrahedral crystals. It is also found in a stalactical form. It melts easily, and then becomes blue. It frequently invests other cobalt ores; and is found sometimes in stone and sand. From the experiments of Bergman, it appears that the arsenical acid, and not the calx of arsenic, enters into this combination; for cobalt is never red but when united to an acid. Flowers of cobalt mineralised by arsenic without any silver, and intermixed with galena, have also been discovered in France. They are often found of a red color, like other earths, spread very thin on the cobalt ores; and, when of a pale color, are erroneously called

flowers of bismuth. The indurated flowers of cobalt are commonly crystallised in form of deep red semitransparent rays. It is found at Schöneberg in Saxony. Cobalt mineralised by sulphurated iron, is of a color nearly resembling tin or silver. It is sometimes found in large masses, sometimes in grains crystallised of a dull white color, and frequently has the appearance of mispickel. It has no mixture of arsenic. By calcination it becomes black and not red, which distinguishes it from the pyrites; and it contains so little sulphur that none can be extracted from it. When dissolved in aqua regia the solution is yellow, but becomes green when boiling; which alteration, according to Kirwin, is peculiar to marine cobalt. A coarse grained kind of this ore, found in Sweden, becomes slimy in the fire, and sticks to the iron rods employed in stirring it while calcining. The slargy kind contains a large quantity of iron, and affords a very beautiful color as well as the former. Cobalt mineralised by sulphur, arsenic, and iron, has a great resemblance to the harder kinds of gray cobalt ore; but it is never hard enough to strike fire with steel, and sometimes may even be scraped with a knife. The most shining kind of this and the former species are called *Kobalt glantz*. The great consumption of cobalt is for the permanent blue color which it communicates to glasses and enamels, either upon metals, porcelains, or earthen wares of any kind; and for the making of small powder blue &c. But although cobalt is applied to few other purposes, the quantities consumed in this way afford sufficient profit to those who have cobalt mines in their possession. Ores of cobalt are met with in the greatest quantities, near Schöneberg in Saxony, and at St. Andreasberg in Upper Hartz. Formerly an iron ore only was found in this place; but about the beginning of the fourteenth century, on sinking deeper, it was succeeded by a very rich ore of silver; which, also, being at length exhausted, gave place to cobalt ores. Some mines, however, are still found in these mines that contain silver and gold. It is supposed that the Chinese, and particularly the Japanese, had formerly mines of excellent cobalt, with which the fine blues of their ancient porcelains were painted; but it appears that these mines are now exhausted, and that the inferior blues of their present wares are painted with the Saxon *cañne*, imported to them by the Dutch. See **CHAMISNEY**.

COBALT, a name applied in Germany, and Saxony, to the damps and arsenical vapors, and their effects on the miners; which has induced the vulgar to apply it to an evil spirit, whom they suppose to dwell in the mines.

COBB Samuel, an English poet, was educated at Christ's Hospital, whence he proceeded to Trinity College, Cambridge, and took his degree of A. M. in 1703. He afterwards became master of the grammar school at Christ's Hospital, but died in 1718, in the prime of life. He wrote 1. Observations on Virgil; 2. a collection of Poems, with a discourse on Criticism and the History of Writing. Svo.; 3. The Miller's Tale, from Chaucer; 4. a Translation of the Muscipula; 5. The Oak and the Brier, a tale; 6. The Female Reign, an Ode.

COBB (James), a dramatic writer, was born in 1756, and became secretary to the East India Company, which office he discharged with great credit till his death in 1818. He wrote the *Humorist*, an opera; *Love in the East*; the *Haunted Tower*; the *Siege of Belgrade*; and several minor pieces, all of which obtained considerable notice.

COBBE, the principal town of the central country of Darfur, Africa. It is situated in the middle of the province, on the great road which penetrates it from north to south, and is said to be more than two miles in length, but very narrow; each house occupying within its enclosure a considerable space of ground, and being separated by a vacant space from the one nearest it. Here reside the principal merchants who conduct the central trade of Africa. In the town appear in great numbers the palm, the delab tree, &c. and two species, called the heglig and the nebbek, which give it an agreeable appearance. The water here, which is drawn from wells filled by the torrents which descend here in the rainy season, though not unwholesome, is turbid, and of an unpleasant taste; in the dry season it often fails. A market is held twice a week for meat and other provisions. Near the town, on the east, is a high mountain of this name abounding with the African tiger and jackal. Long. 23° 8' E., lat. 14° 14' N.

COBBESECONTE, or COPSECOOK, a small river of the United States, district of Maine, which rises from ponds in Wintthrop, and falls into the Kennebeck within three miles of Nahunkear, and fifteen from Moose Island. The name, in the Indian language, signifies the place where sturgeon are taken.

COBBING, a punishment sometimes inflicted at sea. It is performed by striking the offender a certain number of times on the breech with a flat piece of wood, called the cobbing board. It is chiefly used as a punishment to those who quit their station during the period of the night watch. Nor are school-boys unacquainted with it as a diversion.

COBBLE, *v. a.* } Fr. *cobler*; Lat. *copulo*.
COBBLER, *n. s.* } To mend a thing coarsely; literally applied to the mending of shoes; hence, to a clumsy workman in general; a mean and tow occupation.

If you be out, Sir, I can mend you.—Why, Sir, *cobble* you. *Shakspeare. Julius Cæsar.*

What trade are you?—

Truly, Sir, in respect of a fine workman, I am But, as you would say, a *cobbler*. *Id.*

They'll sit by the fire, and presume to know What's done i' the capital; making parties strong, And feeble such as stand not in their liking Below their *cobbled* shoes *Id. Coriolanus.*

Reject the nauseous praises of the times; Give thy base poets back their *cobbled* rhimes. *Dryden*

Think you the great prerogative to enjoy Of doing ill by virtue of that race? As if what we esteem in *cobblers* base Would the high family of Brutus grace. *Id. Juvenal.*

Not many years ago it happened that a *cobbler* had the casting vote for the life of a criminal.

Addison on Italy.

COBDEN (Edward), an ingenious divine and poet, born in 1684. He became rector of St. Austin in London, and of Acton in Middlesex, prebendary of St. Paul's, and archdeacon of London. Dr. Cobden was likewise chaplain in ordinary to George II., but resigned that situation some years before his death, which happened in 1764. He published a volume of poems for the benefit of his curate's widow; and, in 1757, a volume of sermons also.

COBEQUIT, or COLCHESTER, a river of Nova Scotia, which rises within twenty miles of Tatamouche, on the north-east coast; thence runs south, then south-west and west, into the east end of the basin of Minas. There is a short bank at its mouth; but it has a good channel on each side, where by vessels of sixty tons may pass, and go forty miles up the river.

COBIAM, a town of the United States in Virginia, on the south bank of James River, opposite to James town; eleven miles north-west of Smithfield; twenty north-west by north of Suffolk; nine south-west of Williamsburgh; fifty-four east by south of Petersburg; and forty-five south-east of Richmond.

COBI, a desert of Tartary, called Chamo by the Chinese; bounded on the north by the country of the Kalkas; on the east by the Moguls and Chinese Tartary; on the south by China; and on the west by Kalmuc Tartary.

COBIRONS, *n. s.* Cob and iron. Irons with a knob at the upper end.

The implements of the kitchen; as spits, ranges, *cobirons*, and pots. *Bacon's Physical Remains.*

COBISHOP, *n. s.* Con and bishop. A coadjutant bishop.

Valerius, advanced in years, and a Grecian by birth, not qualified to preach in the Latin tongue, made use of Austin as a *cobishop*, for the benefit of the church of Hippo. *Ayliffe.*

COBITIS, the loache, in ichthyology, a genus of fishes belonging to the order of abdominales. The eyes are in the upper part of the head; the branchiostege membrane has from four to five rays; and the body is nearly of an equal thickness throughout. There are six species, of which three are natives of Europe. The loache is found in several of our small rivers, at the bottom on the gravel; and is, on that account, in some places called the groundling; it is common in the stream near Amesbury in Wiltshire, where sportsmen sometimes, in frolic, swallow it alive in a glass of white wine.

COBLE, a boat used in the turbot fishery, twenty feet six inches long, and five feet broad. It is about one ton burden, rowed with three pairs of oars, and admirably constructed for encountering a mountainous sea.

COBLENTZ, an ancient city in the grand duchy of the Lower Rhine, in Germany, in long. 7° 36' E., lat. 50° 23' N., about thirty-six miles north-west of Mentz, forty-eight south-east of Cologne, and fifty-four north-east of Treves. Formerly it was included in the electorate of Treves, afterwards it was made a part of the French republic, and the capital of the department of the Eiffel, and, finally, became subject to Prussia. It stands opposite the fortress of

Ehrenbreitstein, in a rich and fertile country, the mountains of which are covered with vineyards, at the confluence of the rivers Rhine and Moselle. It has a bridge of free-stone over the latter river, but the former is crossed by one constructed of boats. The city is handsome and well built, the streets regularly laid out, the houses of stone, and the public buildings very elegant. The elector of Treves was accustomed to reside here; and, at the beginning of the French revolution, the emigrant princes and nobles made it their principal resort. The palace of the elector is a magnificent building on the bank of the Rhine, on the opposite side of which the old castle stands on the top of a height, with a small collection of houses round it. A ferry machine erected on two boats, in the form of a square gallery, surrounded with balustrades, passes from one side of the river to the other for the convenience of passengers; it is moved by pulling a rope fixed to a standard on each bank. The castle completely commands the city, and seems almost inaccessible; the French, however, under general Marceau, took it after a siege of two hours on the 23rd of October, 1794. Formerly there were two collegiate churches within the city, besides an archiepiscopal seminary, a Jesuit college, and several convents; but the French suppressed most of them. Its population has been differently stated, some making it 12,000 or 13,000, and others under 11,000, which is the most probable calculation, even including the suburbs of Moselweis and Newendorf. This place is very favorably situated for trade, directly communicating with Germany and Switzerland by the Rhine, and with France by means of the Moselle. Great quantities of the best Moselle wine are made here, and exported to Frankfort and Holland; and through this place the Dutch have much of their timber and iron. Wool, linen, and leather, constitute the chief articles of manufacture, but on a small scale. Two yearly fairs, of a fortnight each, are held here.

Cellentia has been celebrated in antiquity. It was known to the Romans, who called it Confluens, or Confluensia, from its situation; in the year 800 a great ecclesiastical council was held in it; and it was counted a free town for a long time before it passed into the possession of the electors of Treves. In 1249 it was fortified with walls, but, during the thirty years' war, it passed successively into the hands of the Swedes, French, Imperialists, and German Protestants. It was besieged by the French in 1683, and almost laid in ashes by a bombardment that it suffered from the castle Ehrenbreitstein; but it did not surrender. It is remarkable for having been made by the Prussians their head quarters, when they were about to invade France; and here the prince of Condé fixed the rendezvous of the emigrants that formed his army. The mineral waters of Tinstern, near this place, are noted, and the baths of Ems, in the neighbourhood of which pumice-stone is found in great abundance. There are two interesting objects near this city, a Carthusian monastery, almost in ruins, and the tomb and fort of general Marceau, who fell in the year 1796.

COBNUT, *n. s.* cob and nut. A boy's game; the conquering nut.

COBOOSE, in sea language, a sort of box, resembling a sentry-box, used to cover the chimneys of some merchant ships. It generally stands against the barricade, on the fore part of the quarter-deck. It is called in the West Indies *Cobra Vera*.

COBOURG, a principality in Germany, situated in the northern part of the circle of Franconia, but dependent on that of Upper Saxony. It is included between $9^{\circ} 50'$ and $12^{\circ} 25'$ E. long., and $50^{\circ} 15'$ and $51^{\circ} 15'$ N. lat., and is bounded on the south by Franconia, on the north and east by Upper Saxony, and on the west by the principality of Hesse. Formerly it belonged to the house of Henneburg, but passed by marriage to that of Saxony, and has been divided into four branches, viz. Saxe-Cobourg, or Saxe-Cobourg Saalfeld, Saxe-Meiningen, Saxe-Gotha, and Saxe-Heilburghausen. The principality of Saxe-Cobourg, properly so called, is the most southerly of the four divisions above mentioned; the mountainous ridge, that passes through them, forming its northern boundary, and Franconia being its boundary on every other side; it lies between $10^{\circ} 35'$ and $11^{\circ} 20'$ E. long., and $50^{\circ} 15'$ and $50^{\circ} 34'$ N. lat. It comprehends about 580 square miles, and a population of 80,000 persons. It is generally a mountainous district, especially through the middle part, including a great part of the Thuringian forest; there are, however, extensive plains, which are very fertile in corn, flax, hops, and fruit, and large pastures for cattle. The inhabitants export corn, wool, cattle, tiles, wood, pitch, and potash, which last article constitutes their chief manufacture; they also make glass, leather, and gunpowder, both for home consumption and exportation. It is watered by several streams, the chief of which are the Itz, or Itach, and the Saale, both running into the Maine, and the Werra, afterwards known by the name of the Weser. Amongst its mineral and fossil productions, may be enumerated iron, copper, coals, marble, alum, gypsum, and chalk. It is under an hereditary government; and the greater part of the people are Lutherans; free toleration, however, is enjoyed here. It supports an army of 800 men, and yields £52,000 revenue.

Cobourg, the capital, lies in a pleasant valley, through which the Itz flows. It is generally well built, and has a handsome square market-place, containing the town-hall and government offices, and a castle, where the prince usually resides. On a hill near the town stands the fort, a place of some strength. Various articles are made here of the petrified wood found in the neighbourhood. Six annual fairs are held, and a great trade carried on in wool. There are about 7000 people in this town, many of whom work in the quarries adjacent. Saalfeld, on the Saale, is the second city, and was formerly a place of great consequence. It once possessed the mint for Upper Saxony; it has yet some public institutions, and silk and cloth manufactures. Not far from it, on an eminence, stands Saalfeld Abbey, a monastery of Benedictines, the abbot of

which was always a German prince, who had a seat in the Diet.

COBSWAN, *n. s.* Cob head, and swan. The head, or leading swan.

I am not taken

With a *cobswan*, or a high-mountain gull,
As foolish Leda and Europa were.

Ben Jonson's Cataline.

COBWEB, *n. s.* Dutch, *kopweb*. The web or net of a spider; from cob, a spider. Any snare or trap; implying insidiousness and weakness.

The luckless Clarion,

With violent swift flight, forth carried
Into the cursed *cobweb*, which his foe
Had framed for his final overthrow. *Spenser.*

Is supper ready, the house trimmed, rushes strowed,
and *cobwebs* swept?

Shakspeare. Taming of the Shrew.

The spider, in the house of a burgher, fell presently
to her net-work of drawing *cobwebs* up and down.

L'Ettrange.

For he a rope of sand could twist
As tough as learned Sorbonist;
And weave fine *cobwebs* fit for scull
That's empty when the moon is full. *Hudibras.*

Chronology at best is but a *cobweb* law, and he
broke through it with his weight. *Dryden.*

Laws are like *cobwebs*, which may catch small flies,
but let wasps and hornets break through. *Swift.*

Drawn by a fraudulent nymph, he gazed, he sigh'd,
Unmindful of his home and distant bride;
She leads the willing victim to his doom,
Through winding alleys to her *cobweb* room. *Gay.*

Laws, as we read in ancient sages
Have been like *cobwebs* in all ages.
Cobwebs for little flies are spread,
And laws for little folks are made. *Beattie.*

COCA, a town of Spain in Old Castile, seated on the Eresma, among the mountains, near a strong castle, which is used as a state prison. It is twenty-four miles E. S. E. of Valladolid, and twenty-two north-west of Segovia. Long. 3° 28' W., lat. 41° 29' N.

COCCEIUS (John), a celebrated Dutch divine, born at Bremen in 1608. When only twenty-seven years of age, he was appointed Hebrew professor in his native city; but afterwards removed to Franeker, and lastly to Leyden, where he filled the theological chair. He distinguished himself by his commentaries on the Old Testament history, which he considered as a mirror, holding forth an accurate view of the transactions and events that were to happen in the church under the New Testament dispensation, and unto the end of the world. The apocalypse was his favorite study; and he maintained the notion of a visible reign of Christ in this world, after a general conversion of the Jews, and other people to the Christian faith. His opinions were warmly controverted; but they had many adherents, who obtained the name of Cocceians. He died at Leyden in 1669. His writings make ten vols. folio.

COCCEIUS (Henry), a German civilian, born at Bremen in 1644. He was educated at Leyden, and afterwards became professor of the law of nature and nations at Heidelberg; on the taking of which place he removed to Utrecht, and lastly

to Frankfort on the Oder. He was created a baron of the empire in 1713, and died in 1719. He published *Juris Publici Prudentia Compendiose exhibitæ*; *Prodromus Justitiæ Gentium*; *Deductiones, Consilia, &c.*; *Theses*, four vols. 4to; and also an improved edition of *Grotius on War and Campaigns*.

COCCIFEROUS, *adj.* From *κοκκός*, and *fero*, Lat. All plants or trees are so called that have berries.

COCCINELLA, in zoology, the lady-bird, a genus of insects of the order of coleoptera. The antennæ are subclavated; the palpi are longer than the antennæ, the last articulation heart-shaped; the body is hemispheric; the thorax and elytra are marginated; the abdomen is flat.

This genus is divided into sections, from the color of the elytra, and of the spots with which they are adorned. The females, impregnated by the males, deposit their eggs, which turn to small larvæ, slow in their progress, and inveterate enemies to the plant-louse. These larvæ are frequently found upon leaves of trees covered with plant-lice. On the point of being metamorphosed, they settle on a leaf by the hinder part of the body, then bend and swell themselves, forming a kind of hook. The skin extends, grows hard, and in a fortnight's time the chrysalis opens along the back. The insect in its perfect state receives the impressions of the air, that gives its elytra a greater degree of consistence. It seldom flies, and cannot keep long on the wing. Of all the different larvæ of the coccinella, the most curious is the white hedge-hog, a name given it by de Reaumur, on account of the singularity of its figure, and the tufts of hair which render it remarkable. It seeks its food on the leaves of trees. After a fortnight it settles on one spot, and, without parting with its fur, turns to a chrysalis; three weeks after which it becomes a coccinella. The slough appears nowise impaired by its transformation. M. de Reaumur has observed it on a plum tree. It is likewise found upon the rose tree. When the coccinellæ first arrives at the state of perfection, the colors of their elytra are very pale, nearly bordering upon white or cream color; and the elytra are very soft and tender, but soon grow hard, and change to very lively brilliant colors. Their eggs are of an oblong form, and of the color of amber.

COCCOCYPSILUM, in botany, a genus of plants of the tetrandria class and monogynia order: CAL. four parted superior: COR. funnel-shaped: SEED an inflated, bilocular berry: STYLE semi-bifid: SPECIES three, shrubs; native of the West Indies.

COCCOLOBA, in botany, a genus of the trigynia order and octandria class of plants; natural order twelfth, holoracæ: CAL. quinque-partite and colored: COR. none: SEED a berry, formed of the calyx, and monopermous. There are thirteen species, of which the principal is the *C. uvifera*, or sea-side grape. It grows upon the sandy shores of most of the West India islands, where it sends up many woody stems, eight or ten feet high, covered with brown smooth bark, and furnished with thick, veined shining, orbicular leaves, five or six inches diameter, standing

upon short foot-stalks. The flowers come out at the wings of the stalks, in racemi of five or six inches long; they are whitish, have no petals, but each is composed of a monophyllous calyx, cut at the hnm into five oblong obtuse segments, which spread open, continue, and surround seven or eight awl-shaped stamina, and three short styles, crowned with simple stigmata. The germen is oval, and becomes a fleshy fruit, wrapped round by the calyx, and includes an oval nut or stone.

COCCLUSISPORUS, the name of a poisonous berry, too frequently mixed with nutmegs to make them intoxicating, though expressly forbidden by act of parliament. It is the fruit of the menispermum cocculus. Fishermen have a way of mixing it with paste; this the fish swallow greedily, and are thereby rendered intoxicated for a time, and float on the water.

COCCLUS, in zoology, a genus of insects belonging to the order of hemiptera. The rostrum proceeds from the breast; the belly is bristly behind; the wings of the male are erect; and the female has no wings. The species are forty-six in number, denominated principally from the plants they frequent. The most remarkable species are: 1. *C. cacti*, a native of the warmer parts of America, the famous cochineal animal, so highly valued in every part of the world for the incomparable beauty of its scarlet color, which it readily communicates to wool and silk, but with much more difficulty to linen and cotton. This insect is of two sexes, but exceedingly dissimilar in their appearance. The female, which alone is valuable for its color, is ill-shaped and tardy; its eyes, mouth, and antennae, are fixed so deep, and are so concealed in the folds of the skin, that it is impossible to distinguish them without a microscope. The male is very scarce; active, small, and slender, in comparison with the female; its neck is narrower than the head, and still narrower than the rest of the body. The male is of a bright red; the female of a deeper color. The cochineal was formerly imagined to be a fruit or seed of some particular plant; an error which probably arose from an ignorance of the manner in which it is propagated. The juice of the nopal leaves on which these insects breed, is their sole nutriment. The plant is in May or June in its most vigorous state, and at this favorable season the eggs are deposited among the leaves. In the short space of two months, from an animalcule, the insect grows up to the size above-mentioned; but its infant state is exposed to a variety of dangers; the violent blasts of the north wind sweep away the eggs from the foliage of the plant; and showers, fogs, and frosts often destroy the leaves, leaving the careful cultivator this only resource, to make fires at certain distances, and fill the air with smoke, which frequently preserves them from the fatal effects of the inclemency of the weather. When the insects are at their full growth, they are gathered and put into pots of earthenware. When they have been confined some time in these pots, they are killed and put in bags. The Indians have three different methods of killing these insects: one by hot water, another by lime, and a third by the fumes of the

sun: and to these are owing the several gradations of the color, which in some is dark, and in others bright; but all require a certain degree of heat: and it must be owned, that among the several ways made use of to destroy this valuable creature, that of the rays of the sun seems to perform it in the most perfect manner. The cochineal insect may, in some circumstances, be compared to the silk-worm, particularly in the manner of depositing its eggs. The insects destined for this purpose are taken at a proper time of their growth, and put into a box well closed, and lined with a coarse cloth that none of them be lost: and in this confinement they lay their eggs and die. The box is kept close shut till the time of placing the eggs on the nopal, when, if any motion is perceived, it is a sufficient indication that the animalcule has life, though the egg is so minute as hardly to be perceived; and this seed is placed on the foliage of the nopal; the quantity contained in the shell of a hen's egg, is sufficient for covering a whole plant. It is remarkable that this insect does not, at least in any visible manner, injure the plant, but extracts its nourishment from the most succulent juice, which it sucks by its proboscis through the fine teguments of the leaves. The principal countries where the cochineal insects are bred are New Spain and Peru; but it is only in Oaxaca, in the former country, that they are gathered in large quantities. Though the cochineal belongs to the animal kingdom, of all others the most liable to corruption, yet it never spoils. Without any other care than merely that of keeping in a box, it has been preserved for ages. In drying it loses about two-thirds of its weight. When dried, it is sined into large entire grains, and small or broken ones; the first are called by the Spaniards *grana*, the latter *granilla*. This insect is said, by Dr. John, to consist of

Cochenilin	50.0
Jelly	10.5
Wax-fat	12.0
Gelatinous mucus	14.0
Sticky matter	14.0
Salts	1.5

110.0

In medicine, cochineal has been strongly recommended as a sudorific, cardiac, and alexipharmic; but practitioners have never observed any considerable effects from it. Its principal consumption is among dyers. See **DYING**. *C. hesperidum*, or the green-house bug, is oval, oblong, and of a brownish color, covered with a kind of varnish; it has six legs, with a notch and four bristles at the tail. It infests orange trees and other similar plants in green-houses. When young, it runs upon the trees; but afterwards it fixes on some leaf, where it hatches a great number of eggs, and dies. The male is a very small fly. *C. ficis*, the insect that forms the *kermes* grains, inhabits the *quercus coccifera* of the southern parts of Europe. Both ancients and moderns seem to have had very confused notions concerning the origin and nature of the *kermes*: since considering it as a fruit, without a just knowledge of the tree which produced it;

others taking it for an excrescence formed by the puncture of a particular fly, the same as the common gall observed upon oaks. The kermes, however, is in reality nothing but the body of an insect transformed into the figure of a grain, berry, or husk, according to the course of nature. At the beginning of March an animalcule, no larger than a grain of millet, scarce able to crawl, is perceived sticking to the branches of the tree, where it fixes itself, and soon becomes immovable; at this period it grows the most, appears to swell and thrive with the sustenance it draws by degrees. This state of rest seems to have deceived the curious observer, it then resembling an excrescence of the bark; during this period of its growth it appears to be covered with a down, extending over its whole frame like a net, and adhering to the bark: its figure is convex, like a small sloe; in such parts as are not quite hidden by this soft garment, many bright specks are perceived of a gold color, as well as stripes running across the body from one space to another. In April its growth is completed; its shape is then round, and about the size of a pea: it has then acquired more strength, and its down is changed into dust, and seems to be nothing but a husk or capsule, full of a reddish juice not unlike discolored blood. Towards the end of May, sooner or later, according to the warmth of the climate, the husk appears replete with small eggs, less than the seed of a poppy. After this it soon dies, though it still adheres to its position, rendering a further service to its progeny, and shielding them from the inclemency of the weather, or the hostile attacks of an enemy. In a good season they multiply exceedingly, having from 1800 to 2000 eggs, which produce the same number of animalcules. When observed with the microscope, in July or August, we find that what appeared as dust, are so many eggs or open capsules, as white as snow, out of each of which issues a gold colored animalcule, of the shape of a cock roach, with two horns, six feet, and a forked tail. In the cidevant province of Languedoc and Provence, the poor are employed to gather the kermes, the women letting their nails grow for that purpose, to pick them off with greater facility. See KERMES.

C. lacca, the gum-lac animal, is a native of the East Indies. The head and trunk form one uniform, oval compressed, red body, of the shape and magnitude of a very small louse, consisting of twelve transverse rings. The back is caranite; the belly flat; the antennæ half the length of the body, sending off two, often three, delicate, diverging, hairs, longer than the antennæ. The tail is a little white point, sending off two horizontal hairs as long as the body. It has three pair of limbs half the length of the insect. This is its description in that state in which it sallies forth from the womb of the parent, in the months of November and December. They traverse the branches of the trees upon which they were produced for some time, and then fix themselves upon the succulent extremities of the young twigs. By the middle of January they are all fixed in their proper situations; they appear as plump as before, but show no other marks of life. The limbs, antennæ, and feet of the tail, are no longer to be

seen. Around their edges they are environed with a spissid subpellucid liquid, which seems to glue them to the branch. The gradual accumulation of this liquid forms a complete cell for each insect, and is what is called gum lacca. About the middle of March the cells are completely formed, and the insect is in appearance an oval, smooth, red bag, without life, about the size of a small cucurbitaceous insect, emarginated at the obtuse end, full of a beautiful red liquid. In October and November we find about twenty or thirty oval eggs, or rather young grubs, within the red fluid of the mother. When this fluid is all expended, the young insects pierce a hole through the back of their mother, and walk off one by one, leaving their exuvie behind, which is that white membranous substance found in the empty cells of the stick lac.

C. polonicus, or the scarlet grain of Poland, an insect which may properly enough be called the cochineal of the northern part of the world. As the cochineal loves only the hot climates, this creature affects only the cold ones. It is collected for the use of dyers: but the crops of it are much smaller, more difficult to be obtained, and the drug itself greatly inferior to the true cochineal. It is gathered in the greatest abundance in Poland, but is also met with in many of the northern countries. It is found affixed to the root of a species of polygonum, of the mouse-ear, rupture-wort, pimpinell, and pellitory of the wall. Towards the end of June the coccus is in a fit state for being gathered. Every one of the creatures is then nearly of a spherical form, of a fine violet color, and full of purple juice. Some of them, however, are not larger than poppy seeds, and others of the size of a pepper corn; and each of them is lodged, either in part or entirely, in a sort of cup like that of an acorn. More than half the surface of the body of the animal is covered by this cup. The outside of the covering is rough, and of a blackish-brown; but the inside is smooth, polished, and shining. On some plants they find only one or two of these, and on others more than forty; and they are sometimes placed near the origin of the stalks of the plant. Each of these produce a six-legged worm, with two antennæ. Several of them have been kept a fortnight, and showed no inclination to eat any thing. They ran about very swiftly for some time; but then began to be more quiet, drew up their bodies shorter, and ceased to run about any longer. They were now of a purple color; but in this state, though they did not walk about, they were subject to various contortions. At length, when wholly motionless, their bodies became covered with a fine white down: this formed a perfect covering, which was sometimes of a spherical, and sometimes of an irregular figure: it was always, however, very elegant; and the downy matter, plainly enough, transpired out of the animal's body. The creatures remained in this state of rest, and covered with this down, for five or six days; but, at the end of that time, every one of them laid more than 150 eggs and died. A sort of very small flies, with two white wings bordered with red, produced from several of these cocci, are supposed to be the males. These flies are plainly of the same kind with the male

gall insects. Those who gather these insects, have a hollow spade with a short handle; then, taking hold of the plant with one hand, they raised it out of the ground with the tool held in the other; after which they very quickly and dexterously detach the insects, and replace the plant in the ground where it again takes root. The coccus is then separated from the earth by a sieve; and, to prevent them from turning into worms, they sprinkle them with very cold water, or vinegar. Lastly, they are killed by exposure to the sun, or by keeping them for some time in a warm place; but this must be done with caution, as too hasty drying would spoil the color. Sometimes they separate the insects from the vesicles with their fingers, and form them into balls; but by this operation their price is greatly increased. It is more expensive than cochineal, as not yielding one-fifth part of the color. Hence this drug is almost entirely fallen into disuse, being scarcely known in any European cities remarkable for having good dyers.

COCCYGIS Os, in anatomy, so called from its resemblance to the bill of a cuckoo; the rump bone. This bone is a small appendage to the point of the sacrum, terminating in an acute point, and differently found according to the different age of the subject. In the child we find but a mere cartilage; in youth jointed bones; in the full grown subject we find one conical bone, though in females the last joint is often loose till the age of sixty. See ANATOMY.

COCHABAMBA, a province of Upper Peru, bounded on the north by the Andes, south-east by the province of Misque, south by that of Charcas, south-west by Oruro, west and north-west by Cioasca. It is 120 miles in length from north to south, and thirty-two wide. This province has been called the granary of Peru. Its western boundary being the Cordillera of the coast of the Pacific, while it extends to the vast plains of Chiquitos East, sloping off toward it in an inclined plane, whose highest altitude is the summit of the Cordillera, and its base a level track which stretches across the Paraguay and Paredes towards the Atlantic; it may be said to contain every variety of climate and soil. In the mountains is great abundance of mineral wealth, but the gold mines of the provinces have been neglected. On their sides are bred considerable quantities of large and small cattle. The climate is generally mild; it is watered by several small rivers, which fertilise the valleys, and among them are some magnificent and well cultivated estates. Tobacco is cultivated successfully in the district of Valle Grande, in this province. Peruvian bark, indigo, and cocoa, are also among its products. It contains many valuable sugar plantations; and is inhabited by a hardy, sober, and brave race, who have risen of late years, with their country, into a considerable state of prosperity in the manufacture of glass, cotton, &c. with which, during the late European wars, it supplied a vast portion of the interior; 1,000,000 pounds of cotton are said to be annually consumed in its manufactures. Salts and all the common minerals abound; and its forests team with dyeing woods and roots. The inhabitants are principally mestizes and cholos, and said to

be both taller and fairer than any of the neighbouring provinces. They have taken a very active part in the late revolutions, and joined the independent government of Buenos Ayres in September 1810. Population about 70,000.

COCHAMBA, or **OROPESA**, the capital of the above province, with a beautiful town situated in a plain on the river Saacabo. Orchards and well cultivated gardens surround it; and avenues of lofty trees skirt the roads, resembling, says an American writer, the great avenues of Versailles.

COCHE, a low and barren island of the Atlantic, between that of Margarita and the coast of Cumana. It is nine miles in circumference, and was formerly celebrated for the pearl fishery. It is twelve miles east of Cubagua. Long. 64° 0' W. lat. 10° 45' N.

COCHECO, a river of the United States, in New Hampshire, which rises in the Blue hills in Stafford county, and after running S. S. E. joins the Piscataqua, five miles above Hilton's Point.

COCHIN, a small province of Hindostan, on the Malabar coast, crossed by the tenth degree of north latitude. It is bounded on the north by the district of Calicut, on the east by part of the southern ridge of the Ghauts, which separates it from Dindigull, on the south by Travancore, and on the west by the Indian Ocean. It is situated between 9° 50' and 10° 45' N. lat. and between 76° 4' and 77° 10' E. long, being about sixty-five miles broad, and seventy-four long. The principal places in this province are, Angicaimal, Arshamichery, Cenotta, Ceavare, Condanada, Mullaventurutti, Naharica, Pallicare, Perimanoor, Pucotta, Putteuchera, and Udiampur. Northwards it consists of narrow valleys, running from the foot of the Ghauts, well watered by constantly flowing streams, and yielding two crops of rice in the year. The natives construct their houses in the thickest parts of the groves, where they are buried amidst palms, mangoes, jacks, and plantains, at the bottom of little eminences crowned with very fine forest-trees, especially the teak-tree, and a species of black wood, called the viti. Little care, however, is taken to encourage the growth of large trees, and check the luxuriance of useless timber. The hills in the neighbourhood of Calicut are not so lofty, and most of them are covered with grass; but though the soil is good, and the land excellent for pasture, a very small part of it is cultivated. The chief products of this country are rice, pepper, cocoa-nuts, and teak-timber. The Paniany River skirts the northern frontier, and several smaller streams water its central and southern parts; but none of them are of any considerable importance. The principal port, and the capital of the province, is Cochín, said to have originated in a fort, which Albuquerque obtained permission to erect, when the Portuguese landed here in 1503. It was taken by the Dutch in 1662, who, it is said, made a warehouse of the cathedral; it, however, became a place of great trade, and flourished much under their dominion. Jews, Hindoos, and Mahomedans resorting to it, and taking up their residence in it for the purposes of commerce, there being a free collection of all religious opinions.

Many of the Arab ships used to make two voyages yearly. It still carries on an extensive commerce with Surat, Bombay, the Malabar coast, Canara, Arabia, China, and many of the eastern islands, exporting pepper, cardamoms, teak and sandal wood, cocoa-nuts, coir cordage, cassia, and fish maws; and importing chiefly almonds, dates, pearls, gum arabic, cotton, opium, benzoin, camphor, cinnamon, spices, sugar-candy, tea, china, silks, shawls, and piece-goods. On the north-east side of this town, at the junction of the river with the sea, there is safe anchorage for vessels, and ships can be built here on very advantageous terms; the cost, when coppered and thoroughly equipped for sea, not exceeding, in the year 1800, £14 per ton. It is called by the natives Cacha Bunder, or harbour. It stands on an island at the mouth of the Cali Coylang, is nearly a semicircle, and about a mile and a-half in circumference. It is regularly fortified, both on the land and water sides, with bastions, a wall, and a ravelin; a wet ditch surrounds it, and a glacis and covered way extend beyond this, so that it could withstand any sudden attack, though it could not abide a regular siege. The streets are wide, and it has three gates; among its buildings, may be particularly specified the church, the house of the governor, the barracks, and a public hotel. The Roman Catholic bishop formerly had his residence here, but when the Dutch took possession of the place he removed to Coilan; his jurisdiction was very extensive, including the whole southern peninsula and the island of Ceylon, comprising more than 100 churches. The English took it in the year 1795, and under their power it still continues. It is governed by a president, under whom is a civil establishment of a judge and other officers, and it has a strong military garrison. Lat. $9^{\circ} 57' N.$, long. $76^{\circ} 8' E.$

The Jews are numerous in this province; but Mattacherry is their principal residence, being almost entirely inhabited by them. There are two classes, the Jerusalem, or White Jews, and the ancient, or Black Jews; the latter, though they have a synagogue in Cochin, chiefly live in the interior, and differ very little in appearance from the Hindoos. They are considered as an inferior race by the White Jews.

The rajah of Cochin preserved his independence much longer than most of the other Hindoo chiefs. Tippoo first exacted a tribute of him, which he paid for some years; but on January 6, 1791, the East India Company entered into a treaty with him, by which he was enabled to throw off his subjection to that prince, to recover some districts of which he had been deprived, and to transfer his allegiance to them, which he accordingly did, agreeing to pay them one lac of rupees annually. A treaty of perpetual friendship was concluded on the 6th May, 1800, by colonel Macauley on the part of the British government, by which the friends and enemies of either party were to be considered and treated as such by both, and the British engaged to defend the rajah's country from all attacks; the rajah engaging to pay an additional annual sum of 176,037 rupees, in order to support a battalion of native infantry, to give the British free access to his

forts and towns, and to exclude from his dominions and service all Europeans not approved of by the English government, to which was to be transferred the management of all his external political concerns.

COCHIN (Charles Nicholas), an excellent artist, and a man of considerable literary abilities, was born in 1715. He was made keeper of the designs in the Louvre, chevalier of the order of St. Michael, and secretary to the academy of painting. He published Letters on the Pictures of Hercules; Dissertation on the Effect of Light and Shade; Travels in Italy, or a Collection of Observations on Works of Architecture, Sculpture, and Painting; Letters on the Lives of Slodz and Ceshays, &c. He died in 1790.

COCHIN (Henry), an eminent French lawyer, born at Paris in 1687. At twenty years of age he was admitted advocate, and two years after pleaded his first cause before the great council. It is said that at the bar, he equalled Bourdaloue in the pulpit. He died in 1747; and his works, consisting of memorials, pleadings, &c. were published at Paris in six volumes quarto, in 1751.

COCHIN-CHINA, or WESTERN CHINA, a name given to this country by the early Portuguese navigators, who discovered it. According to the most accurate calculations, it lies between $8^{\circ} 40'$ and $17^{\circ} N.$ lat., and between $106^{\circ} 40'$ and $102^{\circ} 10' E.$ long. It is very narrow in proportion to its length, extending along the coast not less than 500 miles; and being bounded on the north by Tunquin, on the west by Siam, Cambodia, and Siampa, and on the other sides by the China Sea. These were its original limits, but by conquest they have been much extended, as they now include Tunquin, Cambodia, and Siampa. It is mostly a long narrow plain, enclosed within the sea on one side, and on the other by a long range of mountains separating it from the countries on the west, in few places being more than seventy miles broad, and in some not more than twenty. The breezes, that regularly blow from the sea, so temper the extreme heat of the summer, that the climate is very salubrious. During the months of September, October, and November, the rains set in, and the low grounds are overflowed by torrents that come down from the mountains, and for three or four days every fortnight, deluge the country. Cold northerly winds, followed by rain, prevail during December, January, and February, and distinguish the winters of this country from that of all other eastern regions. The inundations experienced here render the soil remarkably fruitful; in many parts, the land yields three harvests in the year, but generally two, one of which is reaped in April, the other in October. Every tropical production is found here, particularly rice and sugar; the fruits of India, and many of those of China, arrive at the greatest state of perfection. Besides the rice that commonly grows in the plain, there is a particular sort that flourishes on the mountains, called mountain rice. Vast woods of mulberry trees are found here, which grow amazingly fast. There are also many forests of remarkably fine timber, particularly the incorruptible tree, which never rots, and is hard enough for anchors; besides a great quantity of aromatic woods. On

the coast, the sharks'-fins, an animal substance of a gelatinous nature, abound; it is often called *beeche de mer*: and here, also, are found a kind of birds'-nests, which are much in request in China, where they are counted a great delicacy, and used in seasoning ragouts. Here, likewise, a species of cinnamon is cultivated, which, by the Chinese, is esteemed preferable to that of Ceylon. Agula and Japan wood and ivory furnish articles of advantageous commerce. Gold, in great quantities, is brought from the mountains, in dust, and almost pure, or collected in the beds of the rivers among the sand: and silver has lately been abundant. The great men have their arms frequently ornamented with the former article. Among the domestic animals of this country may be enumerated bullocks, goats, swine, horses, buffaloes, elephants, and camels; while the woods abound with the wild boar, tiger, rhinoceros, and large herds of deer: they have also fine poultry, and the fish that is caught in abundance on the coast, is highly delicious. The Cochinese consider the elephant's flesh a great dainty: but, though they use bullocks for food, they do not attend much to the breeding of them, and, they have not the least idea of milking their cattle. The birds'-nests, mentioned above, are found in four islands near the coast, and in five other smaller ones there are prodigious numbers of turtles, the flesh of which is very delicate.

Cochin-China consists of twelve provinces, all bordering on the coast, and extending to the mountainous ridge on the west. In these mountains numerous rivers take their rise, and disembogue their waters in the Eastern Ocean, and, though they are not sufficiently large for vessels of any magnitude to navigate, their importance as to the fertility of the country and its internal commerce can hardly be overrated. The estuaries formed by their mouths and other inlets on the coast furnish very convenient harbours and ports. Turon, or Hansan Bay, in the northern part, is surpassed by none in the eastern world, for its convenience and security, and the promontory overlooking it, forming a peninsula similar to that of Gibraltar on the south of Spain, is not only impregnable, but forms a shelter for ships at every season of the year: while multitudes of rivulets of clear fresh water fertilise the valleys that border the shore. Faifo, an ancient mart for foreign commerce, sometimes regarded as the capital of the country, lies on the banks of a river about ten miles up from this bay. Here is also a considerable port on a river navigable for large ships, but it has a sand bank at the entrance. The bay and harbour of Chin-chew, in the middle division of Chang, is spacious and sheltered, but large vessels can only enter it at high water: at the head of the bay is the city of Quim-nong. Saizong, in the south, has been considered by Mr. Barrow, as situated in Cochin-China, but it is more properly in Cambodia; the largest ships soil up to it, and it has an extensive arsenal for the navy. There is no lake mentioned in this country, but a vast sandy desert seems to stretch along the western limit of it towards Cambodia, for about 250 miles, from the twelfth to the sixteenth degree of latitude. There is no country in

the world on which the sea has made more visible and rapid advances than this; it has been calculated that from 1744 to 1749 it had encroached sixty yards. Some parts of the southern shores are perpendicular, and consist of granite rock, close to which no soundings can be obtained; where the sandy beach is found, there is a gradual descent of sand, mud and shells. In some places the shore consists of ridges of round pebbles, and the bottom is rocky. There is a great irregularity in the tides on the coast; high water continuing in some parts for twelve hours. In summer the tides are lowest, and in winter they rise to the highest degree.

The Cochinese are short in stature, of an olive complexion, and have similar features with the Chinese, so that there can be no doubt of their being of the same origin; but, in some points, they differ widely as to their manners and customs. They are an intelligent, active, and lively people. In their entertainments, superstitions, and ceremonies, they are much like the Chinese: but, with regard to their treatment of women, they are very different. They consider women best suited to conduct the principal concerns of the family; they are, therefore, entrusted with them; and they are generally as free and unrestrained as the men. The lower classes of them are, however, condemned to the most servile labor, while the men are smoking and chewing opium or betel. Mr. Barrow says, 'we observed them day after day, from morning till night, standing in the midst of pools up to their knees occupied in the transplanting of rice. In fact all the labors of tillage, and the various employments connected with agriculture, seem to fall to the share of the female peasantry; while those in Turon add to these the superintendance of all the details of commerce. They even assist in constructing and keeping in repair their mud cottages, conduct the manufacture of coarse earthen vessels, manage the boats on the rivers, and in the harbours; and do everything in the cotton manufacture from the drawing of the wool from the pod, to the making of it up into dresses for themselves and their families.' Unlike the Chinese females, however, they have full liberty and the use of their limbs: but they are licentious, and far from being generally modest. They conduct almost all the commercial business, and, on the arrival of a stranger, it is not difficult for him to procure a female partner, who will be devoted to his service by night and day. In Cochin China a man is not limited to any number of wives or concubines; but the first wife always has the preference, and the chief part of the domestic management. The breaking of a pair of chopsticks, in the presence of witnesses, is sufficient to divorce them. The women are generally dressed in a loose frock of brown or blue cotton, and a pair of black trowsers. They wear neither shoes nor stockings; the higher classes sometimes use sandals. Their hair is long and black, hanging down their shoulders, or fixed in a knot on the top of the head. When in full dress, on occasions of ceremony, they have several gowns one over the other; but differing in length so that the lower parts of all are visible. The men are dressed nearly in the same manner with a

jacket and white short trowsers, and a handkerchief twisted like a turban round the head; hats are sometimes worn of different shapes.

The religion of Cochin China is a form of Buddhism, but more simple, and less mysterious than the rites used in the worship of Fo in China. Like the ancient Jews they offer the first fruits of their ground, and the firstlings of everything else to the image of their protecting deity, as an acknowledgment of his goodness. Their images are generally placed in small wooden boxes, and fixed among the branches of trees in the woods, and here the artless worshipper ascends, deposits his offering, and leaves it to be removed by the priest at his leisure. The people speak a language originally derived from the Chinese; but so much altered, that the natives of the two countries cannot understand each other. It is common to them with the people of Tonquin and the neighbouring countries, and is called the Anam. The written language is in character like the Chinese, and thus an intercourse is readily kept up between them; and, as the government is modelled after the pattern of China, literature is indispensable for office, and of course is widely diffused.

The trade of these people is mostly with the Chinese, to whom they export a great quantity of sugar, particularly sugar-candy, said to be the best in the world, woods, canes, spices, drugs and gold. They also export gum lac, gamboge, indigo, and raw silk in large quantities. The chief article shipped to India is sugar. The French, of all European nations, are treated with most favor, probably on account of the assistance given to the king by a French missionary of the name of Adran; in the European improvements he has been making in his dominions. The Cochin Chinese carry on a considerable trade also with Siam, Cambodia, Tonquin, the coast of Malacca, the Philippine and Molucca islands and Borneo, with which there is a ready communication by the China Sea. Every sort of import into this country pays a duty of twelve per cent., and presents also must be made to the king. Low-priced cutlery and piece-goods find a ready market; but European commodities have not hitherto been much in demand. Tutenaque is said to be in request, dollars are much sought after, and amber and coral, if of a good quality, are saleable in this country.

The government is absolute, as in China; but the police is not so perpetually on the watch, though it is formed upon the same model. The laws likewise are the same in character, and similar in the administration. The Cochin-Chinese are a military people, every third man, of certain ages, being exposed to be called to active service. The army and navy have been much improved during the late period of war. The former consisted of 113,000 men in the year 1800, 40,000 of whom are formed into regiments, and disciplined after the European manner. The effects of this improvement have been witnessed in the late conquest of Tonquin. A great alteration for the better has also taken place in the navy; formerly this consisted entirely of junks similar to those of the Chinese; but under the direction of the French the reigning prince

has, in the course of two years, built 309 gun-boats, a lugger, and a frigate.

The history of this kingdom is little known. M. Le Poivre, a French traveller, informs us that about half a century before the French first arrived in these distant regions, a prince of Tonquin, as he fled from his sovereign, by whom he was pursued as a rebel, had, with his soldiers and adherents, crossed the river, which serves as a barrier between Tonquin and Cochin-China. The fugitives, who were warlike and civilised men, soon expelled the scattered inhabitants, who wandered about without any form of government, and founded a new kingdom, which soon grew rich and populous. During the reigns of the first six kings, no nation could be happier than the Cochin-Chinese. Their monarchs governed them as a father does his family, establishing no laws but those of nature, to which they themselves were the first to pay obedience. They honored and encouraged agriculture, as the most useful employment of mankind; and required from their subjects only a small annual free gift to defray the expense of their defensive war against the Tonquinese, who were their enemies. This imposition was regulated by way of poll-tax, with the greatest equity. Every man, able to till the ground, paid in to the prince a small sum proportioned to the strength of his constitution, and the vigor of his arm; and nothing more. Cochin-China continued happy under these princes for more than a century; but the discovery of gold-mines interrupted their felicity. Luxury immediately took place. The prince began to despise the simple habitation of his ancestors, and caused a superb palace to be built a league in circumference, surrounded with a wall of brick in the model of that Pekin, and defended by 1600 pieces of cannon. Not content with this, he would have three other palaces, for summer, autumn, and winter. The old taxes were by no means sufficient to defray these expences; new ones were devised; and oppression and tyranny everywhere took place. His courtiers, to flatter their prince, gave him the title of the king of heaven, which he still continues to assume. When speaking of his subjects, he styled them his children, but by no means behaved as if he was their father: for our author informs us, that he has seen whole villages newly abandoned by their inhabitants, who were harassed with toil and insupportable exactions; the consequence of which was that their lands returned to their former uncultivated state.

In 1774 three brothers, one a merchant, the second an officer, and the third a priest, expelled the reigning prince from the capital. At this time the young prince Caung Shung with his family, assisted by a French missionary of the name of Adran, fled into the forest, where they concealed themselves for some time; after unsuccessfully endeavouring to make head against the usurpers, they took refuge at Pulowai, a desert island in the gulf of Siam, while Adran went to France to procure assistance, taking with him the prince's eldest son. The prince after enduring various hardships in the above island, landed on his native dominions, expelled the successors of the usurpers, and subsequently

conquered Tonquin. In 1797 and 1798, by the aid of Adran, who had now returned, he effected a number of improvements, opening roads, encouraging cultivation, introducing European discipline into his army and navy, &c. Adran died in 1800, and was buried with great pomp.

COCHINEAL, n. s. Span. *cochinilla*. A wood-louse. An insect gathered upon the opuntia, and dried: from which a beautiful red color is extracted.

COCHINEAL, or COCHENEEL. See COCCUS-CACTI.

COCHLEA. See ANATOMY.

COCHLEA, in zoology. See HELIX.

COCHLEARIA, scurvy-grass: a genus of the siliculososa order, and tetra lymphia class of plants; natural order thirty-ninth, siliculososa. The silicula is emarginated, turgid, and scabrous; with the valves gibbous and obtuse. There are nine species; the most remarkable of which are, 1. *C. angelica*, or garden scurvy-grass, growing naturally on the sea shore, in the north of England and in Holland; but cultivated for use in the gardens near London. It has a fibrous root, from which arise many round succulent leaves, hollowed like a spoon: the stalks rise from six inches to a foot high, and are brittle, and garnished with leaves which are oblong and sinuated. The flowers are produced in clusters at the end of the branches, consisting of four small white petals placed in the form of a cross; and succeeded by short, roundish, swelling seed-vessels, having two cells divided by a thin partition. In each of these are lodged four or five roundish seeds. This plant is propagated by seeds, which should be sown in July, in a moist spot of ground, and in spring they will be fit for use; those that are left will run up to seed in May, and perfect their seeds in June. Scurvy-grass is a pungent stimulating medicine; capable of dissolving viscid juices, opening obstructions of the viscera and the more distant glands, and promoting the more fluid secretions. It is particularly celebrated in scurries, being the principal herb employed in these disorders in the northern countries. 2. *C. armoracia*, or Horse-radish, a plant too well known to need any description. It is propagated by cuttings or buds from the sides of old roots. The best season for this is in October or February; the former for the dry lands, the latter for moist. The root has a quick pungent smell, and penetrating acrid taste; it nevertheless sometimes exudes on the surface. By drying it loses all its acrimony, becoming first sweetish and then almost insipid; but if kept in a cool place, in sand, it retains its qualities for a considerable time. Its culinary use as a stimulant needs no description: the medical effects of it are to stimulate the solids, attenuate the juices, and promote the fluid secretions: it seems to extend its action through the whole habit, and to affect the minutest glands. It has frequently been of service in some kinds of sourries, and other chronic disorders proceeding from a viscidosity of the juices, or obstructions of the excretory ducts. Sydenham recommends it likewise in dropsies, particularly those which follow intermittent fevers. Both water and rectified spirit extracts the virtues of this root by infusion,

and elevate them in distillations: along with an aqueous fluid an essential oil rises, possessing the whole taste and pungency of the horse-radish.

COCHLEARY, adj. ? From *cochlea*, Lat. a **COCHLEATED, adj. ?** Screw. Screw-form: in the form of a screw.

That at St. Dennis, near Paris, hath wreathy spires, and *cochleary* turnings about it, which agreeth with the description of the unicorn's horn in Elian.

Breue's Vulgar Errors.

Two pieces of stone, struck forth of the cavity, of the umbilic of shells, of the same sort with the foregoing: they are of a *cochleated* figure.

Walsford in F. silv.

COCHLÆUS (John), a catholic divine who early and most vigorously opposed the Reformation. He was born at Nuremberg, in 1479, and wrote with great acrimony against Luther, Calvin, Melancthon, &c. especially the former, in a work entitled *De Actis et Scriptis Lutheri*. He also had a controversy with the English divines on the subject of Henry VIII's marriage with Anne Bolyn, and published a curious history of the Hussites, folio. He died at Breslaw, January 10th, 1552.

COCHRANE, Point, the west point of a bay in Prince William Sound, on the west coast of North America. The bay is about a league and a half wide, and three miles deep, terminated by a boundary of ice and frozen snow, reaching from a compact body of lofty frozen mountains to the water's edge. Long. 129° 16' E., lat. 60° 46' N.

COCK, n. s. ? Ang-Sax. *coce*; Fr. *coq*;
COCK-CROWING, ? Gr. *αἰκωγ*: alluding to the call or crowing of a cock, as Lat. *gallus*. A male to the hen, or indeed a male of any species of bird. It is also used to designate superiority, courage, and conquest: whatever is first and best. Cock-crowing is not only the note of the bird, but the note of time.

This gentle owt had in his governance
Seven hennes, for to donne his pleasure,
Which were his sisters and his paramours,
And wonder like to him as of colours;
Of which the fairest-hewed in the throte
Was cleped faire Damoselle Pernelote.

Chaucer's Canterbury Tales.

And now the crowing owt, and now the owle
Lowde shrieking, him afflicten to the very sowle.

Spenser.

We were carousing till the second cock,

Shakspeare.

He begins at curfew, and goes till the first cock. *Id.*

— Might we but hear
The folded dracks pinned in their warded cores,
Or sound of pastoral reed, with oaten pipes,
Or whistle from the lodge or village cock,
Count the night-watches to his feathered chambers,
'Twould be some solace, yet some little cheering
In this close dungeon of innumerable boughs. *Milton.*

Cocks have great combs and spurs; hens, little or none.

Bacon's Natural History.

True cocks of the game,
That never ask for what or whom they fight;
But turn 'em out, and show 'em but a foe.
Cry liberty, and that's a cause of quarrel.

Dryden.

Calves and philosophers, tygers and statesmen, cock-sparrows and coquets, exactly resemble one another in the formation of the pincal gland.

Arbutnot and Pope.

Sir Andrew is the *cock* of the club since he left us.

Addison.

My schoolmaster called me a dunce and a fool ;
But at cuffs I was always the *cock* of the school.

Swift

The careful hen
Calls all her chirping family around,
Fed and defended by the fearless *cock*.

Thomson's Spring.

Cock, *n. s.* Ital. *galletto*. A weather-cock, gnomen of a dial, &c. from the general figure. Things, says Johnson, that were contrived to turn, seem anciently to have had that form, whatever was the reason.

You cataracts and hurricanoes, spout
Till you have drenched our steeples, drowned the
cocks!

Shakspeare.

When every room

Hath blazed with lights, and brayed with minstrelsy,
I have retired me to a wasteful *cock*,
And set mine eyes at flow.

Id.

It were good there were a little *cock* made in the belly of the upper glass.

Bacon's Natural History.

Thus the small jett, which hasty hands unlock,
Spirots in the gardener's eyes who turns the *cock*.

Pope.

Cock, *n. s.* Ital. *cocca*; Fr. *coche*; from Lat. *caso*. The part of a lock of a gun that strikes with a flint; perhaps from the action like that of a cock pecking; but it was, I think, so called, says Dr. Johnson, when it had not its present form. The Ital. *cocca* signifies the notch of an arrow; and thus *cock* is sometimes applied in English.

With hasty rage he snatched
His gunshot, that in holsters watched;
And bending *cock*, he levelled full
Against the outside of Talgol's skull.

Hudibras.

A seven-shot gun carries powder and bullets for seven charges and discharges. Under the breech of the barrel is one box for the powder; a little before the lock another for the bullets; behind the *cock* a charger, which carries the powder from the box to a funnel at the further end of the lock.

Grew.

Cock, *n. s.* Goth. *kog*; Per. *kak*. Small; diminutive; hence *cock-boat*, a little boat.

But thou, good man, sith far in seawe bee,
And the great waters gin apace to swell,
That thou no more we can the mayn-land see,
Have care, I pray, to guide the *cock-bote* well,
Least worse on sea then us on land befell.

Spenser.

This messenger adoune him gan to hie,
And found Jason and Hercules also,
That in a *cogge* to londe weren i'go,
Him to refresken and to take the aire.

Chawer.

The fishermen that walk upon the beach,
Appear like mice; and yon tall anchoring bark
Diminished to her *cock*; her *cock*, a buoy,
Almost too small for sight.

Shakspeare.

They take view of all sized *cocks*, barges, and fisher-beats hovering on the coast.

Carew's Survey of Cornwall.

This invincible armada, which having not fired a cottage of ours at land, nor taken a *cock-boat* of ours at sea, wandered through the wilderness of the northern sea.

Bacon.

Did they think it less dishonor to God to be like a brute, or a plant, or a *cock-boat*, than to be like a man?

Stillingfleet.

Cock, *n. s.* *κόκκος*; Lat. *coccus*. A red color.

Cock, *n. s.* & *v. a.* } The top or head of a

COCKADE, *n. s.* } thing; a hat set up with

COCKAPOOP, *ad.* } pertness or presumption;

probably from the appearance of a *cock*'s comb, and his mode of exhibiting it. It is used therefore to express exultation and triumph; hence, too, when the brim of a hat is raised to a point, it is called a *cocked hat*; and a small heap of hay is for the same reason denominated a *cock*.

Now I am a frisker, all men on me look;
What should I do but set *cock* on the hoop?

Camden's Remains.

You'll make a mutiny among my guests!

You will set *cock-a-hoop!*

Shakspeare.

As soon as the dew is off the ground, spread the hay again, and turn it, that it may wither on the other side: then handle it, and if you find it dry, make it up into *cocks*.

Mortimer.

For Hudibras, who thought he' had won

The field, as certain as a gun,
And having routed the whole troop,
With victory was *cock a hoop*.

Hudibras.

You see many a smart rhetorician turning his hat in his hand, moulding it into several different *cocks*.

Addison.

Cock, *v. a.* & *v. n.* From the noun. To set erect; to hold bolt upright as a *cock* holds his head; to look big and menacing; to raise any thing into a point, or into a round heap; to fix the *cock* of a gun ready for discharge. It is also used in the sense of training *cocks*, or using them for fighting.

Sike mirth in May is meekest for to make,
Or summer shade, under the *cocked* hay.

Spenser's Pastorals.

Cries out 'gainst *cocking*, since he cannot bet.

Ben Jonson.

Some of them holding up their pistols, *cocked*, near the door of the house, which they kept open.

Dryden's Dedication, Æneid.

Sir Fopling is a fool so nicely writ;
The ladies would mistake him for a wit;
And when he sings, talks loud, and *cocks* would cry,
I vow, methinks, he's pretty company.

Dryden.

This is that muscle which performs the motion so often mentioned by the Latin poets, when they talk of a man's *cocking* his noise or playing the rhinoceros.

Addison.

Every one *cocks* and struts upon it, and pretends to overlook us.

Id. Guardian.

An alert young fellow *cocked* his hat upon a friend of his who entered.

Id. Spectator

Dick would *cock* his nose in scorn,
But Tom was kind and loving.

Swift.

Dick, who thus long had passive sat,
Here stroked his chin and *cocked* his hat.

Prior.

But when the bully, with assuming grace,
Cocks his broad hat, edged round with tarnished lace,
Yield not the way; defy his strutting pride,
And thrust him to the muddy kennel's side.

Gay.

Our Lightfoot barks, and *cocks* his ears;
O'er yonder stile see Lubberkin appears.

Id. Pastorals

Cock, in zoology. See PHASIANUS.

COCKATRICE, *n. s.* From cock, and Sax. *accen*, a serpent. A serpent supposed to rise from a cock's egg.

They will kill one another by the look, like *cockatrice*. *Shakspeare.*

This was the end of this little *cockatrice* of a king, that was able to destroy those that did not espy him first. *Bacon.*

This *cockatrice* is soonest crushed in the shell; but, if it grows, it turns to a serpent and a dragon. *Taylor.*

My wife! 'tis she, the very *cockatrice*! *Congreve.*

COCK-BROTH, *n. s.* Broth made by boiling a cock.

Lessius enjoyns so much at supper; not a little more, nor a little less, of such meat, and at such hours, a dyet drink in the morning, *cock-broth*, china broth, at dinner plumb broth, a chicken, a rabbit, rib of a rack of mutton, wing of a capon, merry-thought of a hen, &c. *Burton's Anatomy of Melancholy.*

Diet upon spoon-meats; as veal or *cock-broths* prepared with French barley. *Harvey on Consumptions.*

COCKBURN ISLANDS, a group of small islands near the north-east coast of New Holland, in long. 217° 18' W, lat. 11° 52' S.

COCKBURN LAW, a hill of the county of Berwick, Scotland, about the middle of which, on the north side, are the ruins of a military station, called Edgar's Hall. Height 900 feet.

COCKBURN (Mrs.), daughter of captain Trotter, of the Royal Navy, was born in 1679. At an early age she abjured protestantism for popery; and produced, at the age of seventeen, *Agnes de Castro*, a tragedy, performed with considerable applause. Two years after she wrote the *Fatal Friendship*, a tragedy, which is considered her best piece. She also applied herself early in life to metaphysical pursuits, and wrote, in her twenty-second year, a *Defence of Locke's Essay on the Human Understanding*. Having re-examined the controversy between popery and protestantism, she returned, in 1707, to the established church. In 1708 she married Rev. Mr. Cockburn, a clergyman of that church. His father was a Jacobite, and, in consequence of his own refusal to take the oath of abjuration at the accession of George I., he lost all his preferments in the church, and was obliged to support his family as the usher of a small school. His erudite lady, in 1726, again defended Mr. Locke in a Letter to Dr. Holdsworth on the resurrection of the body; and, in 1727, wrote a further *Vindication of Mr. Locke*, which was printed after her death. She had previously commemorated the victories of the duke of Marlborough in her poems, and written her last tragedy, entitled, the *Revolution of Sweden*. In 1732 her husband, having overcome his scruples, was presented to the living of Long Horseley. Mrs. Cockburn now produced *Remarks upon some Writers in the Controversy concerning the Foundation of Moral Duty and Moral Obligation*, printed in the *History of the Works of the Learned*, in 1743; and in 1747 *Remarks upon the Principles and Reasonings in Dr. Rutherford's Essay on the Nature and Obligations of Virtue*, in *Vindication of the contrary Principles and Reasonings enforced in the Writings of the late Dr. Samuel Clarke*. A plan was now formed of publishing

her works by subscription, but the death of her husband threw her into a painful disease, and she died at Long Horseley in 1749, before her works could be prepared for the press.

COCKER, *v. a.* Fr. *coquelin*. To cade; to fondle; to indulge.

Most children's constitutions are spoiled by *cockering* and tenderness. *Locke on Education.*

He that will give his son sugar-plums to make him learn, does but authorize his love of pleasure, and *cock* up that propensity which he ought to subdue. *Id.*

Bred a fondling and an heiress,

Dressed like any lady mayoress,

Cockered by the servants round,

Was too good to touch the ground. *Swift.*

COCK'ER, *n. s.* From cock. One who follows the sport of cock-fighting.

COCKER (Edward), a celebrated penman and writer on arithmetic in the seventeenth century. He was a native of London, where he was born in 1631, and died in 1677. To his fame we seem to owe the occasional proverb of speech 'According to Cocker.' and Mr. Evelyn celebrates his skill in calligraphy. He published fourteen Copy-books, engraved from his own writing: *Decimal Arithmetic*, and *Vulgar Arithmetic*, of the last of which, it is said, forty editions were sold.

COCKEREL, *n. s.* From cock. A young cock.

Which of them first begins to crow?—

The old cock?—The *cockerel*.

Shakspeare.

What wilt thou be, young *cockerel*, when thy spurs
Are grown to sharpness. *Dryden.*

COCKERMOUTH, a large town of Cumberland, irregularly built, with broad streets. It is washed by the Derwent on the west, and divided by the Cocker into two parts, which are connected by a stone bridge of one single arch. The town, in general, is irregularly built; but there are several modern and well-built streets, particularly the one ascending to the castle-gate, which is very steep; and in that which leads to Derwent-bridge, some of the houses are handsomely built of red free-stone. The manufactures are shal-loons, worsted stockings, and hats. It is a borough town, and sends two members to parliament. The right of voting is vested by burgess tenure in certain houses: the county elections are also held here. It has a castle seated on an artificial mount on a bank above the Derwent. It is a square building, and strengthened with several square towers: on each side of the inner gate are two deep dungeons capable of holding fifty persons each; they are vaulted at top, and have only a small opening to let down the prisoners. On the outside of each is a narrow slit with a slope, down which were dropt their provisions. This castle was founded by Waldef, first lord of Allerdale, and son of Gospatrick earl of Northumberland, contemporary with William the Conqueror. Waldef resided first at Pap-castle, which he afterwards demolished, and with the materials built that of Cocker-mouth, where he and his family long resided. Several arms over the gateway, Camden says, are those of the Multons, Humfravilles, Lucies, and Piercies. In 1658 it was garrisoned for the king, and

being besieged and taken by the rebels, was burnt and never afterwards repaired. Cocker-mouth is now in the possession of the Lowther family, who have here a great property in coal-works. Markets on Monday and Saturday. It is forty-four miles north-west by north of Kendal, and 305 N. N. W. of London.

COCKET, n. s. Of uncertain derivation. A seal belonging to the king's custom-house: likewise a scroll of parchment, sealed and delivered by the officers of the custom-house to merchants, as a warrant that their merchandize is entered.

The greatest profit did arise by the *cocket* of hides; for wool and wool-fells were ever of little value in this kingdom. *Davies.*

COCK-FIGHT, n. s. Cock and fight. A battle, or match of cocks.

In *cock-fights*, to make one cock more hardy, and the other more cowardly. *Bacon's Natural History.*

At the seasons of foot-ball and *cock-fighting*, these little republicks reassume their national hatred to each other. *Addison.*

COCK-FIGHTING is a cruel and inhuman mode of diversion, consisting in setting cocks of a particular kind, hence called game-cocks, to fight with steel spurs, till one or the other is beaten, and can fight no longer. Among the ancients, the islanders of Delos were great lovers of cock-fighting; and Tanagra, a city of Boeotia, the isle of Rhodes, Chalcis in Eubœa, and the country of Media, were famous for their generous race of cocks. From Persia this kind of poultry was first brought into Greece; and, if one may judge of the rest from the fowls of Rhodes and Media, the excellency of the broods, at that time, consisted of their weight and largeness, as the fowls of those countries were heavy and bulky, and of the nature of what our sportsmen call shakebags or turnpokes. At first, cock-fighting was partly a religious and partly a political institution at Athens; and was continued for improving the seeds of valor in the minds of their youth, but was afterwards perverted both there and in the other parts of Greece to a common pastime, without any political or religious intention. The Romans were prone to imitate the Greeks, but did not, as may be gathered from Columella, adopt this practice very early. It is not known when this game was first introduced into England, but it was probably brought hither by the Romans. It has by some been called a royal diversion, and the cock-pit at Whitehall was erected by Charles II. for the more magnificent celebration of it. The birds are generally dieted for about a fortnight or three weeks by regular feeders, who receive for their trouble, in general, the admission-money to the cock-pit. Cocks of a middle size are found the best fighters: the match-weights being from three pounds six ounces to four pounds eight ounces. The place appropriated to fighting is called the pit, and consists, generally, of a mound of earth covered with sod, and surrounded by seats in circular tiers. The battle is conducted by two setters, as they are called, who place the cocks beak to beak.

setters-to can touch his cock, so long as they continue to fight, unless their weapons are entangled. But if they have left off fighting, while the umpire or law-teller can count forty, each setter-to instantly handles his cock, bringing them beak to beak in the middle of the pit, and the cock who made the last fight, with either heel or beak, is said to have the first law in his favor. When brought beak to beak, and set on their legs, if the cock who did not fight while the forty was telling, still continues to decline fighting, the umpire proceeds to tell ten; which being done, they are again brought beak to beak; if the same cock continue still unwilling or unable to fight, the ceremony of telling ten, and bringing beak to beak, at the conclusion of every ten, takes place, till it has been repeated ten different times, when the cock so refusing to fight has lost his battle. But should he fight during the enforcement of any part of the law, what has been told is of no effect, and the first ten must be begun again, whenever a fight is renewed.

If a cock, having the law in his favor, dies before the long law is told out, his adversary wins the battle, although he did not fight within the law; for there cannot be a greater criterion of victory than having killed his opponent.

The following fact is recorded as authentic, in the obituary of the Gentleman's Magazine for April 1789, and is a melancholy instance of the brutalising effects of these cruel sports: 'Died, April 4th, at Tottenham, John Ardesoif, esq. a young man of large fortune, and in the splendor of his carriages and horses rivalled by few country gentlemen. His table was that of hospitality, where it may be said he sacrificed too much to conviviality. Mr. Ardesoif was very fond of cock-fighting, and had a favorite cock upon which he had won many profitable matches. The last bet he laid upon this cock he lost, which so enraged him, that he had the bird d d of a spit and roasted alive before a large fire. The screams of the miserable animal were so affecting, that some gentlemen who were present attempted to interfere, which so enraged Mr. Ardesoif, that he seized a poker, and, with the most furious violence, declared that he would kill the first man who interposed; but, in the midst of his passionate assertions, he fell down dead upon the spot.'

COCK-HORSE, adj. Cock and horse. On horseback; triumphant; exulting.

Alma, they strenuously maintain,
Sits cock-hors'd on her throne the brain. *Prior.*

COCKLE, n. s. Fr. *coquille*. A small testaceous fish.

It is a *cockle* or a walnut-shell. *Shakspeare.*

We may, I think, from the make of an oyster, or *cockle*, reasonably conclude, that it has not so many, nor so quick, senses as a man. *Locke.*

Three common *cockle*-shells out of gravel-pits.
Woodward.

COCKLE, n. s. Sax. *coccel*, Lat. *Iolium zizania*; a weed that grows in corn, the same with cornrose; a species of poppy.

When once the cocks are pitted, neither of the
VOL. VI.

He shal no gospel glosen, here ne teach
 We leven all in the gret God, quod he:
 He wold sowen some difficultec,
 Or springen *cockle* in our clene corn,
 And therefore, Host, I warn thee beforene,
 My jolly body shal a tale tell,
 And I shal clinken you so mery a bell
 That I shall waken all this campagnie

Chaucer's Canterbury Tales.

In soothing them, we nourish 'gainst our senate
 The *cockle* of rebellion, insolence, sedition.

Shakespeare.

Good seed degenerates, and oft obeys
 The soil's disease, and into *cockle* strays.

Donne.

COCKLE, *v. a.* From cockle. To contract
 into wrinkles, like the shell of a cockle.

Showers soon drenched the camblet's *cockled* grain.

Gay.

COCKLED, *adj.* From cockle, Shelled;
 or perhaps cochleate, turbinated.

Love's feeling is more soft and sensible
 Than are the tender horns of *cockled* snails.

Shakespeare.

COCKLE-STAIRS, *n. s.* winding or spiral
 stairs.

COCK-LOFT, *n. s.* Cock and loft. The
 room over the garret, in which fowls are sup-
 posed to roost; unless it be rather corrupted
 from coploit, the cop or top of the house.

If the lower floors already burn,
Cock-lofts and garrets soon will take their turn.

Dryden's Juvenal.

My garrets, or rather my *cock-lofts* indeed, are very
 indifferently furnished; but they are rooms to lay
 lumber in.

Swift.

COCK-MASTER, *n. s.* Cock and master.
 One that breeds game-cocks.

A *cock-master* bought a partridge, and turned it
 among the fighting cocks.

L'Estrange.

COCK-MATCH, *n. s.* Cock and match.
 Cockfight for a prize.

At the same time that the heads of parties preserve
 towards one another an outward shew of good breed-
 ing, their tools will not so much as mingle at a *cock-*
match.

Addison.

Though quail-fighting is what is most taken notice
 of, they had doubtless *cock-matches* also.

Arbuthnot and Pope.

COCKNEY, *n. s.* A word of which the
 original is much controverted. The French use
 an expression *païs de cocaigne*, for a country of
 dainties:—

Paris est pour un riche un *païs de cocaigne.*

Boileau.

Of this word they are not able to settle the
 original. It appears, whatever was its first
 ground, to be very ancient, being mentioned in
 an old Normanno-Saxon poem:—

Far in see by west Spaying,
 Is a lond yhoete cocaying.

One of the writers of the glossary to Chaucer
 has the following note, explanatory of the word.
 That this is a term of contempt, borrowed origi-
 nally from the kitchen, is very probable. A
 cook, in the base Latinity, was called *coquinator*,

and *coquinarius*, from either of which *cokenay*
 might easily be derived. In. p. p. fol. 35, 36.

And yet I say, by my soule, I have no salt bacon,
 Ne no *cokeney* (by Christie) coloppes to make.

It seems to signify a cook. And so, perhaps,
 in the Tournament of Tottenham. Anc. Poet, t.
 ii. p. 24.

At that feast, where they served in rich array,
 Every five and five had a *cokeney*.

That is, I suppose, a cook or scullion to at-
 tend them.—In those rhymes ascribed to Hugh
 Bigot, which Camden has published, Brit.
 Col. 451 (upon what authority I know not)—

Where I in my castle of Bungey

Upon the river of Wavesey,

I would ne care for the king of *Cokeney*.

The author, in calling London Cokeney, might
 possibly allude to that imaginary country of
 idleness and luxury which was anciently known
 by the names of Cocaigne or Cocagne, a name
 which Hickee has shown to be derived from
 coquina. Gn. A. S. p. 231. He has there pub-
 lished an excellent description of the country of
 Cocaigne, in old English verse, but probably
 translated from the French; at least the French
 have had the same fable among them, for Boileau
 plainly alludes to it, sat. vi: in the words already
 cited.

The festival of La Cocagna, at Naples, de-
 scribed by Keyster, v. ii. p. 369, appears to
 have the same foundation. It probably com-
 menced under the Norman government. There is
 a mock heroic poem, in the Sicilian dialect, en-
 titled, La Cuccagna Conquistata, by Gio Baptista
 Basili, Palermo, 1674, in which the description
 of Palma citta di Cuccagna begins thus,—

Sedi *cuccagna* una montagna

Di furmaggju grattatu, et havi in cima

Di maccamni una caudara magna

I lie as a drap-sak in my bedde;
 And when this jape is told another day
 I shal be halden a daffy or a *cokenay*:
 I wol arise and auntere it by my fay:
 Undhardy is unsely—thus men say.

Chaucer's Canterbury Tales.

So the *cockney* did the eels when she put them in
 the pastry alive.

Shakespeare. King Lear.

I am afraid this great lubber, the world, will prove
 a *cockney*.

Id. Twelfth Night.

Some again are in the other extrem, and draw
 this mischief on their heads by too ceremonious and
 strict diet, being over precise, *cockney*-like, and curious
 in their observation of meats.

Burton's Anatomy of Melancholy.

For who is such a *cockney* in his heart,

Proud of the plenty of the southern part,

To scorn that union, by which we may

Boast 'twas his countryman that wrote this play.

Dorset.

The *cockney*, travelling into the country, is surprized
 at many common practices of rural affairs.

Watts.

COCKNEY, KING OF, a title used for the king
 of London, in an ancient poem, ascribed to Hugh
 Bagot, earl of Norfolk, in the time of king Henry
 II. And 'king of the cockney' occurs among
 the regulations for the sports and shows formerly
 held in the Middle Temple on Childermas Day,

where he had his officers; a marshal, constable, butler, &c. See *Dugdale's Origines Juridicales*, p. 247.

COCK-PIT, *n. s.* Cock and pit. The area where cocks fight.

Can this *cock-pit* hold

The vasty field of France.

Shakspeare.

And now I have gained the *cock-pit* of the western world, and academy of arms for many years.

Howell's Vocal Forest.

COCK-PIT, in maritime affairs, a place on the lower deck of a man of war, appropriated to the use of the surgeon and his mates, being the place where the wounded men are dressed in time of battle, or otherwise.

COCK-ROACH. See **BLATTA**.

COCK'S-COMB, *n. s.* Cock and comb. A plant.

COCK'S-HEAD, *n. s.* A plant, named also *sainfoin*.

COCK-SHUT, *n. s.* From cock and shut. The close of the evening, at which time poultry go to roost.

Surrey and himself.

Much about *cock-shut* time, from troop to troop

Went through the army.

Shakspeare.

COCKSPUR, *n. s.* Cock and spur. Virginian hawthorn. A species of medlar.

COCKSURE, *adv.* From cock and sure. Confidently certain; without fear or diffidence. A word of contempt.

We steal, as in a castle, *cocksure*.

Shakspeare.

I thought myself *cocksure* of his horse, which he readily promised me.

Pope's Letters.

COCKSWAIN, *n. s.* Sax. *coggrþane*. The officer who has the command of the cockboat. Corruptly, *coxon*, he sits in the stern of the boat and steers; and has a whistle to call his men.

COCKWEED, *n. s.* From cock and weed. The name of a plant, called also *dittander*, or *peppervort*.

COCLES (Publius Horatius), a celebrated Roman, who alone opposed the whole army of Porsena, king of the Etruscans, at the head of a bridge, while his companions were cutting off the communication with the shore behind him. When the bridge was destroyed, Cocles, though wounded by the darts of the enemy, leapt into the Tiber, and swam across it with his arms. A brazen statue was erected to him in the temple of Vulcan, by the consul Publicola, for his eminent services.

COCOA, *n. s.* Span. *cacaotal*; and therefore more properly written *cacao*. See **CACAO**.

The cacao or chocolate nut is a fruit of an oblong figure; is composed of a thin but hard and woody coat or skin, of a dark blackish colour, and of a dry kernel, filling up its whole cavity, fleshy, dry, firm, and fattish to the touch, of a dusky colour, an agreeable smell, and a pleasant and peculiar taste. It was unknown to us till the discovery of America. The tree is of the thickness of a man's leg, and but a few feet in height; its bark rough, and full of tubercles, and its leaves six or eight inches long, half as much in breadth and pointed at the ends. The flowers are succeeded by the fruit, which is large and oblong, resembling a cucumber, five, six, or eight inches in length, and three or four in thick-

ness; when fully ripe of a purple colour. Within the cavity of this fruit are lodged the *cocoa* nuts usually about thirty in number. *Hill's Materia Medica.*

Amid those orchards of the sun,
Give me to drain the *cocoa's* milky bowl,
And from the palm to draw its fresh'ning wine.

Thomson.

COCOA, in botany. See **COCOS**.

COCOA ISLAND, a small island, part of the group of the Pogy Islands, near the west coast of Sumatra. Long. 100° 30' E., lat. 2° 29' S.

COCOA-NUT BAY, a bay of the Pacific, on the west coast of Robert's Island. Safe anchorage and regular soundings are found from eighteen to five fathoms water; the bottom a fine clear sand; excellent fresh water discharges itself into the bay, near a grove of *cocoa-nut* trees. Long. 219° 48' E., lat. 7° 35' S.

COCOA-NUT ISLAND, a small island near the west coast of Sumatra. Long. 95° 35' E., lat. 4° 38' N. Also a small island at the entrance of Carteret's harbour, on the south-east coast of New Ireland.

COCOA-NUT KEY, a small island in the Spanish main, near the Mosquito shore. Long. 82° 20' W., lat. 15° 52' N.

COCOA-NUT POINT, a cape forming the southern extremity of the island of Gilolo. Long. 128° 26' E., lat. 0° 44' S.

COCONATO, a town of Piedmont, famous for being the birth-place of Christopher Colon, or Columbus. It is four miles south of Crescentio, and twenty east of Turin. Long. 8° 9' E., lat. 45° 5' N.

COCOS, in botany, a genus of the class monœcia, order hexandria; natural order palmæ. Male, *cal.* tripartite: *cor.* tripetalous, with six stamina: female, *cal.* quinquepartite: *cor.* tripetalous: the stigmata three, and the plum coriaceous. Species five, the chief, *C. nucifera*, the *cocoa-nut* tree, is supposed to have been a native of the Maldives and some desert islands in the East Indies: and from thence to have been transported to all the warm parts of America: for it is not found in any of the inland parts, nor anywhere far distant from settlements. It frequently rises sixty feet high. The body of the trunk, which generally leans to one side, occasioned by the great weight of nuts it sustains when young, is of an equal thickness at top and at bottom, but somewhat smaller in the middle; its color is of a pale brown throughout, and the bark smooth. The leaves or branches are often fourteen or fifteen feet long, about twenty-eight in number, winged of a yellow color, straight and tapering. The pinnae are green, often three feet long next the trunk, but diminishing in length toward the extremity of the branches; which are fastened at top by brown stringy threads that grow out of them, of the size of ordinary pack-thread, and are interwoven like a web. The nuts hang at the top of the trunk, in clusters of a dozen in each. Each nut, next the stem, has three holes closely stopped, one being wider and more easily penetrated than the rest. When the kernel begins to grow, it incrusts the inside of the nut in a bluish, jelly-like substance; as this grows harder, the enclosed liquid, distilled

into the nut from the roots, become somewhat acid; and the kernel, as the nut ripens, becomes still more solid; and at length lines the whole inside of the nut for above a quarter of an inch thick, being as white as snow, and of the flavor of an almond. The quantity of liquor in a full grown nut is frequently a pint and upwards. The husky tegument of the nut consists of strong, tough, stringy filaments, which, when removed from the fruit, resemble coarse oakum. The leaves are wrought into brooms, hammocks in form of nets, mats, sacks, and other useful utensils. The tree is propagated by planting the nuts, which, in six or eight weeks, will come up, provided they are fresh and thoroughly ripe; but this is what few of them are when brought into this country; for they are always gathered before they are ripe, that they may keep during the passage. The best way, therefore, would be to gather such nuts as are thoroughly ripe in their native country, and plant them in a tub of dry sand, to keep them from the vermin during the passage. Here they will frequently sprout, which will be an advantage, as they may then be immediately planted in pots of earth, and plunged in the bark-stove. 2. *C. butyracea*. Palm-oil-tree. A native also of South America; unarmed: fronds pinnate: leaflets simple. It is from this species that we obtain the palm-oil of the dispensatories. For a farther account of which see PALM-OIL.

COCOS ISLAND, an island in the Pacific Ocean, abounding, according to captain Vancouver, in fish, and having a fruitful soil. It is about twelve miles in circumference, say those who examined it, lying in a north-east and south-west direction, and about four miles long and two broad, with detached rocks and islets scattered about its shores. Those lying off its south-west part extend to the greatest distance, which is nearly two miles, but they cannot be considered dangerous, because they are sufficiently high to be seen and avoided. Water abounds in every part of the island, of excellent quality, and is to be easily procured at the stations to which vessels can resort. The soil in the immediate neighbourhood of the streams that fall into each of the bays, is of a poor, loose, sandy nature; but, at a little distance, behind the beach and in the fissures of the rocks, a rich black mould was observed, apparently capable of affording much vegetable nourishment. All its vegetable productions appeared to grow luxuriantly, and covered the island in one entire wilderness. On the rocky cliffs, near the sea side, whose uneven surface admitted the growth of vegetables, a coarse kind of grass is produced, that afforded an excellent retreat for the different kinds of sea-fowl which resort thither to roost and build their nests, or, more properly speaking, to lay their eggs, as they are at little pains to form a nest of any description.

About these cliffs grow a very particular kind of trees, something like the cloth-plant of the South Sea Islands, but much larger; some of these grow to the height of about thirty feet, are of a lightish colored bark, free from branches to the top, which is somewhat bushy. Many of the trees that composed the forest, especially in

the interior and elevated parts of the island, seemed to be of a considerable size. The cocoa-nut trees, which grow not only on the sea-shore, but high up on the sides of the hills, were the only trees we saw that bore any fruit, although in one of the rivulets an unripe guava was picked up, which most probably had come from the interior country; in addition to these, we noticed an abundance of different sorts of ferns, some of which produced a stem nearly six inches in diameter, and grew to the height of nearly twenty feet: these, as well as I recollect, were exactly of the same description as those commonly found in New Zealand. Such were the most general vegetable productions of this island that fell under our observation; to which we further added the seeds of apples, peaches, melons, pumpkins, with beans, pease, &c. Fish were in great abundance, and sharks of large size: no turtles were seen; but the shores abounded with rats and land-crabs. All the sea-birds common to tropical regions were found here.* In a bay on the western shore Vancouver's men found a bottle, stating, that the ship *Ratler*, South Sea whaler, of London, had arrived here 26th of July, 1793, and after procuring wood, water, and refreshments, had left a breed of hogs and goats on the island. None of these articles were, however, to be found. Long. 273° 6' E., lat. 5° 35' N.

COCTILE, *adj.* Lat. *coctilis*. Made by baking, as a brick.

COCTION, *n. s.* Lat. *coctio*. The act of boiling.

The disease is sometimes attended with expectoration from the lungs, and that is taken off by a *coction* and resolution of the feverish matter, and terminates in suppuration or a gangrene. *Arbuthnot on Diet.*

COCYTUS, from *κωκυθω*, to weep; one of the rivers of hell, according to the mythology of the poets. It was a branch of the river Styx; and flowed, says Horace, with a dull and languid stream.

COD, *n. s.* } Lat. *capite*; Ital. *capallan*;
 COD-FISH, } Belg. *kabibauer*, from *κεφαλη*,
 Scot. *headcock*, a sea-fish with a large head.

O! spander not thy grief, whose tears command
 To weep upon our *cod* in Newfoundland.
 The plectuous pickle shall preserve the fish,
 And Europe taste thy sorrows in a dish. *Gay.*

COD, *n. s.* Sax. *codde*. Any case or husk in which seeds are lodged.

They corn thou there mayest safely sow,
 Where in full *cods* last year rich pease did grow.

May.
 They let pease lie in small heaps as they are reaped, till they find the hawm and *cod dry*.
Mortimer's Husbandry.

COD, *v. n.* From the noun. To enclose in a cod.

All *codded* grains being a destroyer of weeds, an improver of land, and a preparer of it for other crops. *Mortimer.*

COD, in ichthyology. See GADUS.

COD FISHERY. See FISHERY.

COD, CAPE, a promontory of the United States, on the south side of Boston Bay, in Massachusetts, near the entrance of Boston harbour. It was discovered, and thus named, by Bartholo-

mew Gosnold, in 1602. Long. 70° 10' W., lat. 42° 4' N.

COD, CAPE, a peninsula of Massachusetts, so named from the above cape, which lies on its coast, extending sixty-five miles in length, from the isthmus between Barnstable and Buzzard's Bay to Race Point, and in breadth, for thirty miles, not above three, and above half the remainder from six to nine miles. It is surrounded by water on all sides except the west, where it is bounded by Plymouth county.

CODFERS, *n. s.* From cod. Gatherers of fische.

CODE, *n. s.* Lat. *codex*. A book. A book of the civil law.

We find in the Theodosian and Justinian code the interest of trade very well provided for.

Arbutnot on Coins.

Indentures, covenants, articles they draw,
Large as the fields themselves; and larger far
Than civil codes with all their glosses are.

Pope's Satires.

CODE, in jurisprudence, is a name given by way of eminence to a collection of the laws and constitutions of the Roman emperors, made by order of Justinian. It is accounted the second volume of the civil law, and contains twelve books; the matter of which is nearly the same with that of the digests, especially the first eight books; but the style is neither so pure, nor the method so accurate; and it determines matters of daily use, whereas the digests discuss the more abstruse and subtle questions of the law, giving the various opinions of the ancient lawyers. Although Justinian's code is thus distinguished by the appellation of code, yet there were codes before his time, such as Gregorian code, and Hermogenian code; collections of the Roman laws made by two celebrated lawyers, Gregorius and Hermogenes, which included the constitutions of the emperors from Adrian to Dioclesian and Maximinus. The Theodosian code, comprised in sixteen books, formed out of the constitutions of the emperors from Constantine the Great to Theodosius II., was observed almost over all the west, till it was abrogated by the Justinian code. There are several later codes, particularly the ancient Gothic, and those of the French kings, as the code of Euridic Louis, and Henry, code Marchande, code des Eaux, &c., and latterly we have had the code de Napoleon. See NAPOLEON.

CODE, a considerable river of Panama, South America, on which a large contraband trade being carried on formerly into the Pacific, a tower was built at its mouth. Long. 80° 25' W., lat. 9° 5' N., and taken by the English 1746.

CODEx, in antiquity, a book, or tables on which the ancients wrote, so called à codicibus, or caudicibus arborum, the trunks of trees; the bark of which, being stripped off, served the ancients to write their books on. Codex also denoted a kind of punishment by means of a clog or block of wood, to which slaves who had offended were tied fast, and obliged to drag it along with them; and sometimes they sat on it closely bound.

CODIA, among botanists, signifies the head of

any plant, but more particularly a poppy head; whence its syrup is called *codicidium*.

CODIA, in botany, a genus of the digyna order, and octandria class of plants: *cal.* tetraphyllous, with small oblong horizontal leaves; *cor.* consists of four very small linear petals; *stam.* eight filaments, twice as long as the calyx; anthers roundish. Species, one only, a native of New Caledonia.

CODICILL, *n. s.* Lat. *codicillus*. An appendage to a will.

The man suspects his lady's crying,

Was but to gain him to appoint her,
By *codicil* a larger jointure. *Prin.*

CODICILL, in law, a supplement to a will which it resembles, except that it makes no mention of an heir or executor, and is not written with the formalities prescribed for a testament; so that a codicil is a less solemn will, of one that dies either testate or intestate, with or without the appointment of an heir; testate, when he that hath made his codicil had, either before or afterwards, made his testament, on which this codicil depends, or to which it refers; intestate, when one leaves behind him only a codicil without a testament, when he gives legacies to be paid only by the heir at law.

CODDLE, *n. s.* Fr. *codille*; Sp. *codillo*. A term of reproach when the game is won.

She scold and tremol'd at the approaching ill,
J. and the laws of civil *codice*.

Pope's Rape of the Lock.

To **CODDLE**, *v. a.* Lat. *coquo*, *coctulo*. To parboil; to soften by the heat of water.

CODDLING, *n. s.* From To *coddle*. An apple generally coddled to be mixed with milk.

In July come gilliflowers of all varieties, early
pears and plums in fruit, conning's and *collings*.

Bacon's Essays.

Their entertainment at the height,
In cream and *collings* revelling with delight.

King's Cuckery.

He let it lie all winter in a gravel walk, south of
a *colling* hedge. *Mortimer's Husbandry.*

A *colling*, ere it went his lip in,
Would straight become a golden-pippin. *Swift.*

CODIGNO, a town of Italy, in the elevated duchy of Milan, situated in the department of Adda, near the confluence of the Adda and the Po. It was the head-quarters of the French general Laharpe, when he was shot by the Austrians, in May, 1796, though the French were victorious. It was also the scene of a defeat of the Austrians, fifty years before, in 1746. It lies thirty-three miles east of Pavia, and ten S. S. E. of Udina. Lon. 10° 59' E., lat. 45° 6' N.

CODON, *κοδων*, in antiquity, a cymbal, or rather little brass bell, resembling the head of a poppy. They were fastened to the trappings and bridles of horses.

CODON, in botany, a genus of the monogynia order, and decandria class of plants: *cal.* decempartite, with the segments alternately long and short; *cor.* campanulate, with the limb decempartite and equal; the nectarium decemlocular, of ten scales inserted into the heels of the stamina; the seed-case bilocular; the seeds hairy, roundish, in a dry colored pulp. Species eight, one only a Cypre plant.

CODRINGTON (Christopher), a celebrated English officer, born at Barbadoes in 1668, and educated at Oxford; after which he betook himself to the army; and, by his merit and courage, soon recommending himself to the favor of king William, was made a captain in the first regiment of foot guards. He was at the siege of Namur in 1695; and, upon the peace of Ryswick, was made governor in chief of the Leeward and Caribbee islands. In 1701, however, several articles were exhibited against him before the House of Commons; to which he published a distinct and particular answer, and was honorably acquitted. In 1703, he showed great bravery at the attack of Guadaloupe; but at last he lived a studious and retired life. He died at Barbadoes April 7th, 1710, and was buried there; but his body was afterwards brought over to England, and interred, in 1716, at Oxford. By his last will, he bequeathed his plantations in Barbadoes, and part of the island of Barbuda, to the Society for Propagating the Gospel in Foreign parts; and left a noble legacy to All Souls College, of which he had been a fellow. This legacy consisted of his library, which was valued at £6000, and £10,000 to be laid out; £6000 in building a library, and £4000 in furnishing it with books. He wrote some of the poems in the *Musæ Anglicanæ*, printed at London in 1741.

COD ROY, a river of Newfoundland, which runs into the sea between cape Ray and cape Anguille.

CODRUS, the seventeenth and last king of Athens, son of Melanthus. When the Heraclidæ made war against Athens, the oracle foretold that the victory would be granted to that nation whose king was killed in battle. The Heraclidæ upon this gave strict orders to spare the life of Codrus; but the patriotic king disguised himself and attacked one of the enemy, by whom he was killed. The Athenians obtained the victory, and Codrus was deservedly called the father of his country. He reigned twenty-one years, about A. A. C. 1071. To pay the more honor to his memory, the Athenians enacted, that no man after Codrus should reign in Athens, under the name of king. See *ATICA*.

COD'S HEAD, a cape on the south-west coast of Ireland. Long. 9° 59' W., lat 51° 36' N.

COECK (Peter), called also Peter Van Aelst, was a Flemish painter of the school of Bernard of Brussels. In 1531 he went to Constantinople, and made some admirable drawings of the Turkish costume, which he afterwards cut in wood. His historical pictures, as well as portraits, have been much admired. He was painter to Charles V. and died at Antwerp in 1550.

CŒCUM, in anatomy, the blind gut; so called as it has but one opening, being the first portion of the large intestine in which the small intestine ends. See *ANATOMY* and *INTESTINES*.

COEFFICACY, *n. s.* Lat. *con* and *efficacia*. The power of several things acting together to produce an effect.

We cannot in general infer the efficacy of those stars, or *coefficient* particular in medications

Eroune's Vulgar Errors.

COEFFICIENCY, *n. s.*; *con* and *efficio*.

Lat. *co-operation*; the state of acting together to some single end.

The managing and carrying on of this work by the spirits instrumental *coefficienty*, requires that they be kept together without distinction or dissipation.

Glauville's Scep sis.

COEFFICIENTS. See *ALGEBRA*.

COEFFICIENT. *n. s.* Lat. *con* and *efficiens*. 1. That which unites its action with the action of another. 2. In algebra; such numbers, or given quantities, that are put before letters, or unknown quantities, into which letters they are supposed to be multiplied, and so do make a rectangle or product, with the letters; as 4 *a*, *b* *x*, *c* *x* *x*; where 4 is the coefficient of 4 *a*, *b* of *b* *x*, and *c* of *c* *x* *x*.

The *coefficient* of any generating term in fluxions, is the quantity arising by the division of that term, by the generated quantity. *Chambers.*

CŒLIAC ARTERY. See *ANATOMY*. Index.

CŒLIAC PASSION. *Κολίτα* the belly. A diarrhœa, or flux, that arises from the indigestion or putrefaction of food in the stomach and bowels, whereby the aliment comes away little altered from what it was when eaten, or changed like corrupted stinking flesh.

CŒLIAC VEIN, in anatomy, that which runs through the intestinum rectum, along with the cœliac artery.

CŒLIOMONTANA PORTA, one of the gates of Rome, situated at the mouth of mount Cœlius, and hence its name: thought to be the ancient Asinaria by some. By this gate Alaric, with his Goths, is said to have entered and plundered Rome.

CŒLIOBRIGA, in ancient geography, a town of the Bracari in the Hither Spain, south of Bracara Augusta, north of the Durus, and not far from the Atlantic. It was a municipium, and is now thought to be Barcelona.

COELIUS MOUS, one of the seven hills of Rome; so called from Coeles, a Tuscan captain, who came to the assistance of Romulus against the Sabines, according to Dionysius Halicarnassus. It was called also Querculanus, or Quercetulanus, from the oaks growing on it; and Augustus by Tiberius. To the east it had the city walls, on the south the Coeliolus, to the west the Palatine, and on the north the Esquiline.

CELOS PORTUS, a town of the Chersonesus, near Sestos; where the Athenians erected a trophy, after a sea victory over the Lacedæmonians.

COEMPTION, *n. s.* Lat. *coemptio*. The act of buying up the whole quantity of anything.

Monopolies and *coemption* of wares for resale, where they are not restrained, are great means to enrich. *Bacon's Essays.*

COEMPTIONALES, among the Romans, an appellation given to old slaves, who were sold in a lot with others, because they could not be alone.

COEN (John Paterson), governor of the Dutch settlements in the East Indies, and founder of the city of Batavia, was born at Hloorn in 1587. He was educated in Italy for a commercial life, and afterwards went to India, where he introduced the Italian mode of book keeping. He suc-

ceeded to the governorship of Bantam in 1617, but two years after he removed the factory to Batavia, which city he planned and built. In 1623 he returned to Europe, but in 1627 he went back to Batavia, which he defended with great bravery against the emperor Java, who lost such a great number of men before the place, that the dead carcasses produced a pestilence, of which Coen died in 1629.

CENOBITE, from *κοινος*, common, and *βιος*, life, a religious who lives in a convent, or in community, under a certain rule; in opposition to a hermit, who lives in solitude. Cassian makes this difference between a convent and monastery, that the latter may be applied to the residence of a single religious or recluse; whereas the convent implies cœnobites, or numbers of religious living in common. Fleury speaks of three kinds of monks in Egypt: anachorets, who live in solitude; cœnobites, who continue to live in community; and sarabaites, who are a kind of monks errant, that stroll from place to place. He refers the institution of cœnobites to the times of the apostles, and makes it a kind of imitation of the ordinary lives of the faithful at Jerusalem; though St. Pachomiurs is ordinarily allowed to have been the institutor of the cœnoblite life; as being the first who gave a rule to any community.

CENOBIVM, *κοινοβιον*, the state of living in a society, or community, where all things are common. Pythagoras is thought to be the author or institutor of this kind of life; his disciples, though some hundreds in number, being obliged to give up all their private estates, to be annexed to the joint stock of the whole. The Essenians among the Jews and Platonists are said to have lived in the same manner. Many Christians also have thought this the most perfect kind of society, as being that in which Christ and his apostles chose to live.

COEQUAL, *adj.* } From Lat. *con* and
COEQUALITY, *n. s.* } *equalis*, equal; being of the same rank and dignity, with another.

Henry the fifth did sometimes prophesy,

If once he came to be a cardinal,

He'll make his cap *coequal* with the crown.

Shakspeare. Henry IV.

COERCE, *v. a.* } Lat. *coerceo*; to restrain;
COERCIBLE, *adj.* } to keep in order by force;
COERCION, *n. s.* } penal restraint; check.
COERCIVE, *adj.* } That which has the power and authority of restraining by punishment.

For ministers to seek that themselves might have *coercive* power over the church, would have been hardly construed. *Hooker's Preface.*

The *coercion* or execution of the sentence in ecclesiastical courts, is only by excommunication of the person contumacious. *Hale's Common Law.*

The virtues of a general, or a king, are prudence, counsel, active fortitude, *coercive* power, awful command, and the exercise of magnanimity, as well as justice. *Dryden.*

Government has *coercion* and animadversion upon such as neglect their duty; without which *coercive* power, all government is toothless and precarious. *South.*

COESSENTIAL, *adj.* } Lat. *con* and *essen-*
COESSENTIALITY, *n. s.* } *tia*. Participating of the same essence.

The Lord our God is but one God, in which indivisible unity we adore the Father, as being altogether of himself; we glory that consubstantial Word, which is the Son; we bless and magnify that *coessential* Spirit eternally proceeding from both, which is the Holy Ghost. *Hooker.*

COETANEUS, *adj.* Lat. *con* and *atus*. Of the same age with another: with *to*.

Eve was old as Adam, and Cain their son *coetaneous* unto both. *Broune's Vulgar Errors.*

Every fault hath penal effects, *coetaneous* to the act. *Gov.*

Through the body every member sustains another; and all are *coetaneous*, because none can subsist alone. *Bentley's Sermons.*

COETERNAL, *adj.* } Lat. *con* and *eternus*.
COETERNALLY, *adv.* } Having existence from
COETERNITY, *n. s.* } eternity. In a state of equal eternity with another.

Arius had dishonored his *coeternally* begotten Son. *Hooker.*

The eternity of the Son's generation, and his *coeternity* and consubstantiality with the Father, when he came down from heaven, and was incarnate. *Hammond's Fundamentals.*

Hail! holy Light! offspring of Heaven first-born,
Or of the Eternal *coeternal* beam,
May I express thee, unblamed: since God is light,
And never but in unapproached light
Dwelt from eternity, dwelt then in thee,
Bright effluence of bright essence increate. *Milton.*

COEVAL, *adj.* & *n. s.* } Lat. *coævus*. The
COEVOUS, *adj.* } same in age; a contemporary; but properly one not only living at the same time, but of the same time of life.

This religion cannot pretend to be *coeval* with man. *Hale.*

Although we had no monuments of religion ancienter than idolatry, we have no reason to conclude that idolatrous religion was *coeval* to mankind. *Id. Origin of Mankind.*

The monthly revolutions of the moon, or the diurnal of the earth upon its own axis, by the very hypothesis, are *coeval* with the former. *Bentley.*

Then it should not have been the first, as supposing some other thing *coævous* to it. *South.*

Even his teeth and white, like a young flock,
Coeval, and new-shorn, from the clear brook
Recent. *Prior.*

As it were not enough to have outdone all your *coevals* in wit, you will excel them in good nature. *Popc.*

Silence, *coeval* with eternity!
Thou wert, ere nature first began to be,
'Twas one vast nothing all, and all slept fast in thee!
Id.

O my *coevals*! remnants of yourselves!
Poor human ruins tottering o'er the grave!
Shall we, shall aged men, like aged trees,
Strike deeper their vile root, and closer cling
Still more enamoured of this wretched soil?
Young's Night Thoughts.

Describe the man of whom
His own *coevals* took but little note,
And paint his person, character, and views
As they had known him from his mother's womb.
Cowper's Task.

COEVORDEU, or KORVORDE, a fortified town, the capital of the district of Drenthe, in the Netherlands; situated on the river Aa. It has been regarded as the chief d'œuvre of the celebrated Coehorn, and one of the strongest fortresses of Holland, forming the key to Groningen, Overijssel, and Friesland. Its form is that of a regular pentagon, with high and thick ramparts, seven large bastions, seven half moons, and seven ravelins. It is farther strengthened by a fort surrounded with five other bastions, and surrounded by marshes. It was besieged in 1672 by Bernard Von Galen, the warlike bishop of Munster, and betrayed by the governor; but shortly after retaken by the Dutch. In 1795 it surrendered to the French. It is thirty miles south of Groningen, thirty-six north-east of Deventer, and sixty north-east of Arnheim.

COEUR (James), an opulent French merchant of the fifteenth century. He is said to have had 300 agents in the Levant, and lent 200,000 crowns of gold to Charles VII. which enabled him to conquer Normandy. He was, in return, tried upon some false charges, and condemned to the loss of his estates, and the payment of an enormous fine. He himself only escaped through the management of one of his clerks, and died in the isle of Chio in 1456.

COEXIST, *v. n.* } Lat. *con* and *existo*.
 COEXISTENCE, *n. s.* } To exist at the same time
 COEXISTENT, *adj.* } with another. Existence
 together; equal in time and duration.

The three stars that *coexist* in heavenly constellations, are a multitude of stars.

Hale's Origin of Mankind.

Of substances no one has any clear idea, farther than of certain simple ideas *coexisting* together. *Locke.*

It is sufficient that we have the idea of the length of any regular periodical appearances, which we can in our minds apply to duration, with which the motion or appearance never *coexisted*. *Id.*

The measuring of any duration, by some motion, depends not on the real *coexistence* of that thing to that motion, or any other periods of revolution. *Id.*

To the measuring the duration of anything by time, it is not requisite that that thing should be *coexistent* to the motion we measure by, or any other periodical revolution. *Id.*

All that one point is either future or past, and no parts are *coexistent* or contemporary with it. *Bentley.*

We can demonstrate the being of God's eternal ideas, and their *coexistence* with him.

Grav's Cosmologia.

COEXTEND, *v. a.* } Lat. *con* and *extendo*.
 COEXTENSION, *n. s.* } To extend to the same
 space or duration with another.

Though it be a spirit, I find it is no inconvenience to have some analogy, at least of *coextension* with my body. *Hale.*

Every motion is, in some sort *coextended* with the body moved. *Grav's Cosmologia.*

COFFEA, the coffee-tree, a genus of the monogynia order, and pentandria class of plants; natural order forty-seventh, stellate: cor. funnel-shaped; the stamina above the tube: SEED, a berry inferior, dispermous, and arillated. There are ten species, but our limits confine us to the description of one only, the *C. Arabica*.

It seldom rises more than sixteen or eighteen feet in height; the main stem grows upright, and is covered with a light brown bark; the branches are produced horizontally and opposite, crossing each other at every joint; so that every side of the tree is fully garnished with them, and they form a sort of pyramid. The leaves also stand opposite; and when fully grown are about four or five inches long, and two broad in the middle, decreasing towards each end; the borders are waved, and the surface of a lucid green. The flowers are produced in clusters at the root of the leaves, close to the branches; they are tubulous, and spread open at the top, where they are divided into five parts; are of a pure white, and have a very grateful odor, but are of short duration. The fruit, which is the only useful part, resembles a cherry. It grows in clusters, and is ranged along the branches under the axillæ of the leaves, of the same green as the laurel, but something longer. When it comes to be of a deep red, it is gathered for the mill, in order to be manufactured into coffee beans. The coffee-tree is cultivated in Arabia, Persia, the East Indies, the Isle of Bourbon, and several parts of America. It is also raised in botanic gardens in several parts of Europe. Prince Eugene's garden at Vienna produced more coffee than was sufficient for his own consumption. It delights particularly in hills and mountains, where its root is almost always dry, and its head frequently watered with gentle showers. It prefers a western aspect, and ploughed ground without any appearance of grass. The plants should be placed eight feet distant from each other, in holes twelve or fifteen inches deep. They should rise to the height of sixteen or eighteen feet, but they are generally stunted to five, for the conveniency of gathering their fruit with the greater ease. Thus dwarfed, they extend their branches so, that they cover the whole spot round them. They begin to yield fruit the third year, but are not in full bearing till the fifth. They are in danger of being destroyed by worms, or by the scorching rays of the sun. The hills where the coffee trees are found have, generally, a gravelly or chalky bottom. In the last it languishes for some time, and then dies: in the former its roots, which seldom fail of striking between stones, obtain nourishment, and keep the tree alive and fruitful for thirty years. This is nearly the period for plants of the coffee tree. The proprietor, at the end of this period, not only finds himself without trees, but has his land reduced, that it is not fit for any kind of culture; and unless he is so situated, that he can break up a spot of virgin land, to make himself amends for that which is totally exhausted by the coffee trees, his loss is irreparable. The coffee produced in Arabia is found so greatly to excel that raised in the American plantations or elsewhere, that the cultivation of the tree is now but seldom practised in any of the British colonies. Large plantations of this kind were formerly made in some of them; and it was proposed to the parliament to give a proper encouragement for cultivating this commodity there, so as to enable the planters to undersell the importers from Arabia. Accordingly there was an abatement of the duty pay-

able on all coffee imported from our colonies in America, which was then supposed to be sufficient encouragement for this kind of commerce; but the inferiority of the American coffee to the Arabian, almost ruined the project. The coffee berry is very apt to imbibe moisture, or the flavor of anything placed near it. Some years ago a coffee ship from India had a few bags of pepper put on board, the flavor of which was imbibed by the coffee, and the whole cargo spoiled. The coffee tree, when cultivated in Europe, requires a stove. It makes a fine appearance at all seasons of the year (being an evergreen), but especially when in flower, and when the berries are red, which is generally in the winter, as they continue long in that state. It is propagated from the berries; but they must be planted immediately when gathered from the tree, for they lose their vegetative quality in a very short time; when sent abroad by the post, they have constantly failed when they have been a fortnight on their journey; so that where these trees are desired, the young plants must be sent, if it be at any distance from the place where they grow. The fresh berries may be planted in small pots, and plunged into a hot-bed of tanner's bark. The most proper soil for them is that of a kitchen garden, which is naturally loose, and not subject to bind, especially if it has constantly been well wrought and dunged.

The mill for dressing the coffee beans is composed of two wooden rollers furnished with iron plates, eighteen inches long, and ten or twelve in diameter. These movable rollers are made to approach a third, which is fixed, and called the chops. Above the rollers is a hopper, in which the coffee is put, from whence it falls between the rollers and the chops, where it is stripped of its first skin, and divided into two parts, as may be seen by the form of it, after it has undergone this operation; being flat on one side and round on the other. From this machine it falls into a brass seive, where the skin drops between the wires, while the fruit slides over them into baskets placed ready to receive it: it is then thrown into a vessel full of water, where it soaks for one night, and is afterwards thoroughly washed. When the whole is finished, and well dried, it is put into another machine called the peeling mill. This is a wooden grinder, turned vertically upon its trendle by a mule or horse. In passing over the coffee it takes off the parchment, which is nothing but a thin skin that detaches itself from the berry in proportion as it grows dry. The parchment being removed it is taken out of this mill to be put into another, which is called the winnowing mill. This machine is provided with four pieces of tin fixed upon an axle, which is turned by a slave with considerable force: and the wind that is made by the motion of these plates clears the coffee from all the pellicles that are mixed with it. It is afterwards put upon a table, where the broken berries, and any filth that may remain among them, are separated by negroes, after which the coffee is fit for sale.

It is prepared by roasting, or giving it a just degree of torrefaction on an earthen or metal-line plate, till it has acquired a brownish hue, equally deep on all sides. As much is then

ground in a mill, as serves the present occasion. A proper quantity of water is then boiled, and the ground coffee put into it. After it has just boiled it is taken from the fire, and the decoction having stood awhile to settle, it is poured into dishes. The ordinary method of roasting coffee among us is in a tin cylindrical box full of holes, through the middle whereof runs a spit. Under this is a semicircular hearth, whereon is a large charcoal fire: by the help of a jack the spit turns swift, and so roasts the berry, being now and then taken up to be shaken. When the oil rises, and it is grown of a dark brown color, it is emptied into two receivers made with hoops, whose bottoms are iron plates; there the coffee is shaken, and left till almost cold, and if it look bright and oily it is a sign it is well done.

COFFEE, *n. s.* } From the Arab. *cahub*;
COFFEE-POT, *n. s.* } *caffè*.. The tree is a species of Arabian jessamine; used also for the berry, and the beverage made from it.

They have in Turkey a drink called *caffè*, made of a berry of the same name, as black as soot, and of a strong scent, but not aromatical; which they take beaten into powder, in water, as hot as they can drink it. This drink comforteth the brain and heart, and helpeth digestion. *Bacon.*

To part her time 'twixt reading and behen,
Or o'er cold *caffè* trille with the spoon. *Pope.*

It is found to succeed as well in the Caribbee islands as in its native place of growth; but whether the *caffè* produced in the West Indies will prove as good as that from Mocha in Arabia Felix, time will discover. *Miller.*

Coffèe denotes a drink prepared from the berries, very familiar in Europe for these eighty years, and among the Turks for 190. Thevenot, the traveller, was the first who brought it into France; and a Greek servant, called Pasqua, brought into England by Mr. Daniel Edwards, a Turki y merchant, in 1652, to make his *caffèe*, first set up the profession of *caffèe*-man, and introduced the drink among us. *Chambers.*

COFFEE, the well-known beverage prepared from the berry of this tree, has now been familiar in Europe for upwards of 200 years. Its origin is not well known. Some ascribe it to the prior of a monastery; who, being informed by a goatherd that his cattle, sometimes browsing on the tree, would wake and caper all night, became curious to prove its virtue. Accordingly he first tried it on his monks, to prevent their sleeping at matins. Others refer the invention of coffee to the Persians; from whom it was received, we are told, in the fifteenth century by Gemaluddin, a mufti of Aden, who, having tried its virtues himself, and found that it dissipated the fumes which oppressed the head, and prevented sleep, recommended it first to his dervises, with whom he used to spend the night in prayer. Hence it passed to Mecca, where first the devotees, and afterwards the rest of the people, took it. From Arabia Felix it passed to Cairo. It 1511 Kâkîe Beg prohibited it, from a persuasion that it inebriated; but Sultan Causon immediately after took off the prohibition, and coffee advanced from Egypt to Syria and Constantinople. The dervises declaimed against it from the Alcoran, which declares, that coal is not of the number of things created by God for food. Accordingly, the mufti ordered the coffee houses to be shut;

but his successor declaring coffee not to be coal, they were again open. During the war in Candia, these assemblies furnishing opportunities for the discussion of politics, the grand vizier Kiu Prili suppressed the coffee-houses at Constantinople; which suppression, however, did not prevent the public use of the liquor there. The word coffee is originally Arabic; the Turks pronounce it it cahuh, and the Arabians caluah; which some authors maintain to be a general name for anything that takes away the appetite; others, for anything that promotes appetite: and others again, for anything that gives strength and vigor. The Mahomedans, it is observed, distinguish three kinds of cahuh. The first is wine, or any liquor that inebriates; the second is made of the pods that contain the coffee berry; this they call the sultan's coffee, from their having first introduced, on account of its heating less than the berry, as well as its keeping the bowels open; the third is that made with the berry itself, which alone is used in Europe, the pods being found improper for transportation.

With respect to the medicinal properties of coffee, it is, in general, excitant and stimulating; though we doubt whether it relaxes the animal fibres, as has by some authors been supposed. Its more or less wholesome effect greatly depends on the climate, as well as the age, constitution, and other peculiarities of the individual. Hence it cannot be recommended to children, or persons of a hot choleric, nervous, or phthisical habit; nor will it be so safe and useful in warm as in cold and temperate climates; but to the phlegmatic and sedentary, a cup of coffee one or two hours after a meal, or, which is still better, one hour before it, may be of service to promote digestion, and prevent or remove a propensity to sleep. In cases of spasmodic asthma, hypochondriasis, serofula, diarrhœa, agues, and particularly against narcotic poisons, such as opium, hemlock, &c. coffee often produces the best effects; nor is there a domestic remedy better adapted to relieve periodical headaches which proceed from want of tone, or from debility of the stomach.

COFFEE-HOUSE. } A tavern or subscription
COFFEE-MAN. } meeting where refreshments are sold. A house of public entertainment; a tavern. Coffee-man is the obsolete term for tavern-keeper, or one that keeps a coffee-house.

The Turks have a drink called coffa (for they use no wine), so named of a berry as black as soot, and as bitter (like that black drink which was in use amongst the Lacedæmonians, and perhaps the same), which they sip still of, and sup as warm as they can suffer; they spend much time in those *coffa-houses*, which are somewhat like our ale-houses or taverns; and there they sit clating and drinking, to drive away the time, and to be merry together, because they find by experience that kind of drink so used helpeth digestion, and procureth alacrity. *Burton's Anat. Mel.*

At ten, from *coffee-house* or play
Returning, finishes the day. *Prior.*

It is a point they do not concern themselves about, farther than perhaps as a subject in a *coffee-house*.

Sicily.
Consider your enemies the Lacedæmonians.

ever you hear that they preferred a *coffee-man* to Agasilans? *Addison.*

COFFEE TREE, in botany. See **COFFEA**.

COFFER, *n. s.* & *v. a.* Sax. cofe; Fr. *coffre*. A chest; a depository for treasure; and, by a metonymy, treasure itself.

And had this sergeant that he prively
Shulde this child, ful softe, wind and wrappe,
With all circumstances tenderly,
And carry it in a *coffre*, or in a lappe.

Chaucer's Canterbury Tales.

Treasure, as a war might draw forth, so a peace succeeding, might *coffer* up. *Bacon's Henry VII.*

He would discharge it without any burthen to the queen's *coffers*, for honor's sake.

Id. Advice to Villiers.

Two iron *coffers* hung on either side,
With precious metal full as they could hold.

Færie Queene.

The lining of his *coffers* shall make coats
To deck our soldiers for these Irish wars.

Shakespeare's Richard II.

If you destroy your governour that is wealthy, you must chuse another, who will fill his *coffers* out of what is left. *L'Estrange.*

COFFER, in architecture, a square dépression in each interval between the modillions of the Corinthian cornice, usually filled with some enrichment.

COFFER, in fortification, a hollow lodgment across a dry moat, from six to seven feet deep, and from sixteen to eighteen broad; the upper part being made of pieces of timber, raised two feet above the level of the moat; which little elevation has hurdles laden with earth for its covering, and serves as a parapet, with embrasures.

COFFER, in fortification, is nearly the same with the caponiere, excepting that this last is sometimes made beyond the counterscarp on the glacis; and the coffer always in the moat taking up its whole breadth, which the caponiere does not. It differs from the travers and gallery in that these are made by the besiegers, and the coffer by the besieged. The besieged generally make use of coffers to repulse the besiegers when they endeavour to pass the ditch. To save themselves from the fire of these coffers, the besiegers throw up the earth on that side towards the coffer.

COFFER DAM, in architecture, an enclosure used in laying the foundation of the piers of bridges. It is generally constructed by driving piles in double rows, and ramming clay and rubbish between them. The water being pumped out, leaves a dry foundation for the working of the pier.

COFFERER OF THE KING'S HOUSEHOLD, was a white staff officer, and always a member of the privy council. This officer is now suppressed, and the business of his office is transacted by the lord steward, and paymaster of the household.

COFFIN, *n. s.* & *n. a.* Fr. *coffin*; from **COF-FIN-MAKER**, *n. s.* Lat. *cavus*. A chest for dead bodies. Technically used in farriery.

Would'st thou have laugh'd had I come *coffined* home,
That werpest to see me triumph.

S. Agnes's Cocks.

Not a flower sweet
On my black *coffin* let there be strown.

Id. Twelfth Night.

Let me lie
In prison, and here be *coffined* when I die. *Donne.*

He went as if he had been the *coffin* that carried
himself to his sepulchre. *Sidney.*

One fate they have,
The ship their *coffin*, and the sea their grave. *Wall.*

The joiner is fitting screws to your *coffin*. *Swift.*

Coffin of a horse, is the whole hoof of the foot above
the coronet, including the *coffin* bone. The *coffin*
bone is a small spongy bone, inclosed in the midst of
the hoof and possessing the whole form of the foot.

Farrier's Dictionary.

Where will be your sextons, *coffin-makers*, and
plumbers. *Tatler.*

COFFIN. The sepulchral honors paid to de-
parted friends in ancient times, are curious and
worthy of attention. Their being put into a
coffin was considered as a mark of the highest dis-
tinction; though with us the poorest people have
their coffins. At this day, in the east, they are
not at all made use of, either by Turks or Chris-
tians. The ancient Jews seem to have buried their
dead in the same manner: neither was the
body of our Lord, it should seem, put into a
coffin; nor that of Elisha, 2 Kings, xiii. 21,
whose bones were touched by the corpse that was
let down a little after into the sepulchre. That
coffins, however, were anciently made use of in
Egypt, all agree; and antique coffins of stone,
and sycamore wood, are still to be seen in that
country; not to mention those said to be of a
kind of pasteboard, formed by folding or gluing
cloth together a great many times, curiously
plastered, and then painted with hieroglyphics.
Its being an ancient Egyptian custom, and not
practised in the neighbouring countries, was,
doubtless, the cause that the sacred historian ex-
pressly observes of Joseph, that he was not only
embalmed, but also put into a coffin, Gen. l. 26,
both being customs peculiar to the Egyptians.
Maillet apprehends that all were not enclosed in
coffins who were laid in the Egyptian repositories
of the dead; but that it was an honor appro-
priated to persons of rank.

COG, v. a., v. n. & n. s. } Bar. Lat. *coga*.
CO'GGER, n. s. } A wedge; the
tooth of a wheel. The verb is applied to the
employment of a wedge, or to the fixing the
teeth in a wheel. As a corruption of cocker it
means to flatter; to deceive. To cog a die is
to give a bias to dice; to play unfairly. It ge-
nerally signifies to obtrude by falsehood; to lie;
to wheedle.

I'll mountebank their loves,
Cog their hearts from them, and come home beloved
Of all the trades in Rome. *Shakspeare. Coriolanus.*

Mrs. Ford, I cannot cog; I cannot prate, Mrs.
Ford: now shall I sin in my wish.

Id. Merry Wives of Windsor.

But then my study was to cog the die,
And dexterously to throw the lucky side.

Dryden's Per. Satires.

For guineas in other men's breeches,
Your gamblers will palm and will cog. *Swift.*

Ye gallants of Newgate, whose fingers are nice
In diving in pockets, or cogging of dice. *Id.*

ne outcry is, that I abuse his demonstration by
a falsification, by cogging in the word.

Tillotson. Preface.

I have cogged in the word to serve my turn.

Stillingfleet.

Fustian tragedies, or insipid comedies, have, by
concerted applauses, been cogged upon the town for
masterpieces.

Dennis.

Or more expert in pilfering vice,

They burn and itch to cog the dice.

Gay.

COGAN (Thomas, M. D.), was born in 1736,
at Rowell, in Northamptonshire. Educated at
Kilworth under Dr. Aikin, he was intended for
the dissenting ministry, and officiated for some
time to a Presbyterian congregation at Amster-
dam, where he married a lady of fortune. He
now studied physick, and in 1767 took his doc-
tor's degree at Leydon. Some time after we
find him in London, uniting with the late Dr.
Hawes in instituting the Royal Humane Society.
He returned, however, to Holland, till the French
revolution obliged him once more to come to
England, where he published, in 1794, *The*
Rhine, or a Journey from Utrecht to Frankfort;
and, in 1795, the works of Camper. His other
works are, 1. *Philosophical Treatise on the Passions*;
2. *Ethical Questions, or Speculations in*
Moral Philosophy; 3. *Theological Disquisitions*,
5 vols. 8vo. He was also the author of *the Life*
and *Opinions of John Bunce, jun.*; and *Letters*
on the *Doctrine of Hereditary Depravity*. He
died February 2nd, 1818.

CO'GENT, adj. } Lat. *cogens*. Forcible; re-
CO'GENCY, n. s. } sistless; convincing; power-
CO'GENTLY, adv. } ful; having the power to
compel; conviction.

Maxims and axioms, principles of science, because
they are self evident, have been supposed innate;
although nobody ever shewed the foundation of their
clearness and cogency. *Locke.*

They forbid us to hearken to those proofs, as weak
or fallacious, which our own existence, and the sen-
sible parts of the universe, offer so clearly and co-
gently to our thoughts. *Id.*

Such is the cogent force of nature. *Prior.*

They have contrived methods of deceit, one repug-
nant to another, to evade, if possible, this most cogent
proof of a Deity. *Bentley.*

CO'GGLESTONE, n. s. Ital. *cuogolo*. A
little stone; a small pebble.

CO'GITATE, v. n. Lat. *cogito*. To think;
CO'GITABLE, adj. } to purpose; to medi-
CO'GITATION, n. s. } tate; to reflect; to in-
CO'GITATIVE, adj. } dulse mental specula-
tion.

Having their cogitations darkened, and being stran-
gers from the life of God, from the ignorance which is
in them. *Hooker.*

The king, perceiving that his desires were intem-
perate, and his cogitations vast and irregular, began
not to brook him well. *Bacon's Henry VII.*

On some great charge employed

He seemed, or fixt in cogitation deep.

Milton's Paradise Lost.

The earl had the closer and more reserved coun-
tenance, being by nature more cogitative. *Watson.*

If these powers of cogitation and sensation are
neither inherent in matter, nor acquirable to mat-
ter, they proceed from some cogitative substance,
which we call spirit and soul. *Bentley.*

COGNAC, **COGNAC**, or **COIGNAC**, a town of France, in the department of the Charente, and ci-devant province of Angoumois, with a castle, where Francis I. was born. It is seated on the river Charente, in a very pleasant country, abounding in wine and remarkable for its excellent brandy: it trades largely in it with all the chief cities of Europe. It is 100 miles south-west of Paris.

COGNAC, a town of France, in the department of Upper Vienne, and ci-devant province of Limosin, twenty miles south-east of Consolet.

COGNATION, *n. s.* Lat. *cognatio*. Kindred; descent from the same original. Relation; participation of the same nature.

He induceth us to ascribe effects unto causes of no *cognition*. *Broune's Vulgar Errors.*

Two vices I hall mention, as being of near *cognition* to ingratitude; pride, and hard-heartedness, or want of compassion. *South.*

Let the criticsk tell me what certain sense they could put upon either of these four words, by their mere *cognativa* with each other. *Watts on the Mind.*

COGNISEE, *n. s.* In law. He to whom a fine in lands or tenements is acknowledged.

COGNISOUR, *n. s.* In law. Is he that passeth or acknowledgeth a fine in lands or tenements to another.

COGNITION, *n. s.* } Lat. *cognitio*. Know-
COGNITIVE, *adj.* } led; e; complete con-
viction. Having the power of knowing.

I will not be myself, nor have *cognition*

Of what I feel; I am all patience.

Shakspeare. Troilus and Cressida.

God, as he created all things, so is he beyond and in them all; not only in power, as under his subjection; or in his presence, as in his *cognition*; but in their very essence, as in the soul of their casualities.

Broune's Vulgar Errors.

Unless the understanding employ and exercise its *cognitive* or apprehensive power about these terms, there can be no actual apprehension of them.

South's Sermons.

COGNITIONIS CAUSA, in Scots law. When a creditor charges the heir of his debtor to enter, in order to constitute the debt against him, and the heir renounces the succession, the creditor can obtain no decret of constitution of that debt against the heir; but only a decret subjecting the hereditas jacens, or the estate which belonged to the debtor, to his diligence: and this is called a decret *cognitionis causa*.

COGNIZABLE, *adj.* } Fr. *cognoisable*, con-
COGNIZANCE, *n. s.* } *noissance*. That falls under judicial notice: liable to be tried, judged, or examined. Judicial notice; trial; judicial authority; a badge, by which any one is known.

And at the king's going away the earl's servants stood, in a seemly manner, in their livery coats, with *cognizances*, ranged on both sides, and made the king a bow.

Bacon's Henry VII.

These were the proper *cognizances* and coat-arms of the tribes.

Broune's Vulgar Errors.

Some are merely of ecclesiastical *cognizance*; others of a mixed nature, such as are *cognizable* both in the ecclesiastical and secular courts.

Ayliffe's Parergon.

It is worth the while, however, to consider how we may discountenance and prevent those evils which the law can take no *cognizance* of.

L'Etrange.

Happiness or misery, in converse with others, depends upon things which human laws can take no *cognizance* of.

South.

The moral crime is completed, there are only circumstances wanting to work it up for the *cognizance* of the law.

Addison.

COGNIZANCE OF PLEAS is an authority to call a cause or plea out of another court, which no person can do but the king, except he can show a charter for it. This *cognizance* is a privilege granted to a city or a town to hold plea of all contracts, &c. within the liberty; and if any one is implicated for such matters in the courts at Westminster, the mayor, &c. of such franchise may demand *cognizance* of the plea, and that it may be determined before them.

COGNOMEN, in Roman antiquity, a family surname, such as Scipio, Cæsar, Antoninus, &c., in addition to the nomen, or family name, Cornelius, Julius, Aurelius, &c., and differing from the agnomen, such as Africanus, &c. in being heritable. See **AGNOMEN**.

COGNOMINAL, *adj.* } Lat. *cognomen*.

COGNOMINATION, *n. s.* } Having the same name; a surname; the name of a family; a name added from any accident or quality.

Nor do those animals more resemble the creatures on earth, than they on earth the constellations, which pass under animal names in heaven; nor the dog-fish at sea much more make out the dog of the land, than this *cognominal* or namesake in the heavens.

Broune's Vulgar Errors.

Pompey deserved the name Great; Alexander, of the same *cognomination*, was generalissimo of Greece.

Brown.

COGNOSANCE, *n. s.* } Lat. *cognosco*.

COGNOSCIBLE, *adj.* } Knowledge; the state or act of knowing. That may be known; being the object of knowledge.

The same that is said for the redundance of matters intelligible and *cognoscible* in things natural, may be applied to things artificial.

Hale's Origin of Mankind.

COHABIT, *v. a.* } Lat. *cohabito*. To
COHABITANT, *n. s.* } dwell with another in
COHABITATION, *n. s.* } the same place. To live together as husband and wife.

Which defect, though it could not evacuate a marriage after *cohabitation*, and actual consummation, yet it was not enough to make void a contract.

Bacon's Henry VII.

The Philistines were worsted by the captivated ark, which feraged their country more than a conquering army; they were not able to *cohabit* with that holy thing.

South.

The oppressed Indians protest against that heaven where the Spaiiards are to be their *cohabitants*.

Decay of Piety.

He knew her not to be his own wife, and yet had a design to *cohabit* with her as such.

Fiddes's Sermons.

Monsieur Brumars, at one hundred and two years, died for love of his wife, who was ninety-two at her death, after seventy years *cohabitation*.

Tatler.

COHABITATION, in law, denotes the state of a man and woman who live together as if married. By the common law of Scotland *cohabitation*, for a year and a day, or a complete twelve-month, is deemed equivalent to matrimony.

COHANZY, or CAESARIA, a small river of New Jersey, which rises in Salem county, and, after running south-east for a few miles through Cumberland county, and afterwards S.S.W., falls into the Delaware, opposite to the upper end of Bombay Hook. It is about thirty miles long, and navigable, for vessels of 100 tons, twenty miles from its mouth.

COHASSET, a township of Massachusetts, in Norfolk county, which was incorporated in 1770, and contains 817 inhabitants, 126 houses, and a congregational church. It is twenty-five miles south-east of Boston, but not thirteen in a direct line.

COHASSET ROCKS, dangerous rocks about three miles from the coast of Cohasset, which have proved fatal to many vessels.

COHEIR, *n. s.* } Lat. *coharces*. One of
COHEIRESS, *n. s.* } several among whom an inheritance is divided: when the shares are equal. The difference of termination marks the sex.

Married persons, and widows, and virgins, are all *coheirs* in the inheritance of Jesus, if they live within the laws of their estate. *Taylor's Holy Lie.*

COHERE, *v. n.* } Lat. *coharere*. To stick
COHERENCY, *n. s.* } together; to hold fast
COHERENCY, *n. s.* } one to another, as parts
COHERENT, *adj.* } of the same mass. To
COHESION, *n. s.* } be well connected; to
COHESIVE, *adv.* } follow regularly in the
COHESIVENESS, *n. s.* } order of discourse; to
suit; to fit; to be fitted to.

It shall be no trouble to find each controversy's resting-place, and the *coherence* it hath with things, either on which it dependeth, or which depend on it.

Hooker's Preface.

Had time *cohered* with place, or place with wishing.
Shakspeare.

Instruct my daughter,
That time and place, with this deceit so lawful,
May prove *coherent*.

Shakspeare. All's Well that Ends Well.

In their tender years, ideas that have no natural *cohesion*, come to be united in their heads. *Locke.*

The mind proceeds from the knowledge it stands possessed of already, to that which lies next, and is *coherent* to it, and so on to what it aims at. *Id.*

Coherence of discourse, and a direct tendency of all the parts of it to the argument in hand, are most eminently to be found in him.

Id. Preface to St. Paul's Epistles.

The pressure of the air will not explain, nor can be a cause of, the *coherence* of the particles of air themselves. *Id.*

Matter is either fluid or solid; words that may comprehend the middle degrees between extreme fixeness and *coherency*, and the most rapid intestine motion. *Dentley.*

None want a place; for all their centre found,
Hung to the goddess, and *cohered* around;
Not closer, orb in orb englobed, are seen
The buzzing bees about their dusky queen.

Pope's Dunciad.

Two pieces of marble, having their surface exactly plain, polite, and applied to each other in such a manner as to intercept the air, do *cohere* firmly together as one. *Woodward.*

By coagulating and diluting, that is, making their parts more or less *coherent*. *Arbuthnot on Aliments.*

Solids and fluids differ in the degree of *cohesion*, which, being increased, turns a fluid into a solid. *Id.*

What cause of their *cohesion* can you find?

What props support, what chains the fabric bind?

Blackmore.

A *coherent* thinker, and a strict reasoner, is not to be made at once by a set of rules. *Watts's Logic.*

COHESION, in natural philosophy, is that property by which the parts of bodies adhere together. This power was first considered by Sir Isaac Newton as one of the properties essential to all matter, and the cause of that variety which we observe in the texture of different terrestrial bodies. He did not, however, absolutely determine that the power of cohesion was an immaterial one; but thought it might possibly arise, as well as that of gravitation, from the action of an ether. His account of the original constitution of matter is as follows:—It seems probable, that God in the beginning formed matter in solid, massy, impenetrable, movable particles; of such sizes, figures, and other properties, and in such proportion to space as most conduced to the end for which he formed them: and that these primitive principles, being solid, are incomparably harder than any porous bodies composed of them; even so very hard as never to wear or break in pieces; no ordinary power being able to divide what God himself made at the first creation. While the particles continue entire they may compose bodies of one and the same nature and texture in all ages; but should they wear away, or break in pieces, the nature of all things depending on them would be changed. Water and earth, composed of old worn particles and fragments of particles, would not now be of the same texture with water and earth composed of entire particles in the beginning; and therefore, that nature may be lasting, the changes of corporeal things are to be placed in the various separations and new associations and motions of these permanent particles: compound bodies being apt to break, not in the midst of solid particles, but where these particles are laid together, and touch in a few points. It seems further, that these particles have not only a vis inertia, accompanied with such passive laws of motion as naturally result from that force, but also that they are moved by certain active principles, such as that of gravity, and that which causes fermentation and the cohesion of bodies. These principles are to be considered not as occult qualities, supposed to result from the specific forms of things, but as general laws of nature by which the things themselves are formed; their truth appearing to us by phenomena, though their cause is not yet discovered. The general law of nature, by which all the different bodies in the universe are composed, according to Sir Isaac Newton, is that of attraction: i. e. 'Every particle of matter has attractive force, or a tendency to every other particle; which power is strongest in the point of contact, and suddenly decreases, insomuch that it acts no more at the least sensible distance, and, at a greater distance, is converted into a repellent force, whereby the parts fly from each other.

‘On this principle of attraction may we account for the cohesion of bodies, otherwise inexpli-

cable. The smallest particles may cohere by the strongest attractions, and compose bigger particles of weaker virtue; and many of these may cohere, and compose bigger particles, whose virtue is still less; and so on for divers successions, until the progression end in the biggest particles, on which the operations in chemistry, and the colors of natural bodies, depend; and which, by cohering, compose bodies of a sensible magnitude. If the body is compact, and bends or yields inward to pressure without any sliding of its parts, it is hard and elastic; returning to its figure with a force arising from the mutual attraction of its parts. If the parts slide from one another, the body is malleable or soft. If they slip easily, and are of a fit size to be agitated by heat, and the heat is great enough to keep them in agitation, the body is fluid; and, if it be apt to stick to things, it is humid; and the drops of every fluid affect a round figure by the mutual attractions of their parts, as the globe of the earth and sea affects a round figure from the mutual attraction and gravity of its parts. Since metals dissolved in acids attract but a small quantity of the acid, their attractive force reaches but to a small distance. Now, as in algebra, where affirmative quantities cease, their negative ones begin; so in mechanics, where attraction ceases, there a repulsive virtue must succeed. That there really is such a virtue seems to follow from the reflections and inflections of the rays of light; the rays being repelled by bodies in both these cases without the immediate contact of the reflecting or inflecting body. The same thing seems also to follow from the emission of light; a ray, as soon as shaken off from a body by the vibrating motion of the parts of the body, and got beyond the reach of attraction, being driven away with exceeding great velocity; for that force which is sufficient to turn it back in reflection, may be sufficient to emit it. From the same repelling power it seems to be that flies walk upon the water without wetting their feet; that the object-glasses of long telescopes lie upon one another without touching; and that dry powders are difficultly made to touch one another so as to stick together, without melting them or wetting them with water, which, by exhaling may bring them together. The particles of all hard, homogeneous bodies which touch one another, cohere with a great force: to account for which, some philosophers have recourse to a kind of hooked atoms, which in effect is nothing else but to beg the question. Others imagine, that the particles of bodies are connected by rest, i. e. in effect by nothing at all; and others, by conspiring motions, i. e. by a relative rest among themselves. For myself, it rather appears to me that the particles of bodies cohere by an attractive force, whereby they tend mutually to each other.

From the above account of the formation and constitution of bodies, we can conclude nothing, except that they are composed of an infinite number of little particles, kept together by a force or power; but of what nature that power is, whether material or immaterial, we must remain ignorant till farther experiments are made. Some of the Newtonian philosophers, however,

have positively determined these powers to be immaterial. In consequence of this supposition, they have so refined upon attractions and repulsions, that their systems seem not far from downright scepticism, or denying the existence of matter altogether. A system of this kind we find adopted by Dr. Priestley, in his History of Vision, vol. i. p. 332, from Messrs. Boscovich and Mitchell, in order to solve some difficulties concerning the Newtonian doctrine of light. 'The easiest method,' says he, 'of solving all difficulties, is to adopt the hypothesis of Mr. Boscovich, who supposes that matter is not impenetrable, as has been perhaps universally taken for granted; but that it consists of physical points only, endued with powers of attraction and repulsion in the same manner as solid matter is generally supposed to be: provided therefore that any body move with a sufficient degree of velocity, or have a sufficient momentum to overcome any powers of repulsion that it may meet with, it will find no difficulty in making its way through any body whatever; for nothing else will penetrate one another but powers, such as we know do in fact exist in the same place, and counterbalance or over-rule one another. The most obvious difficulty, and indeed almost the only one that attends this hypothesis, as it supposes the mutual penetrability of matter arises from the idea of the nature of matter, and the difficulty we meet with in attempting to force two bodies into the same place. But it is demonstrable that the first obstruction arises from no actual contact of matter, but from mere powers of repulsion. This difficulty we can overcome; and, having got within one sphere of repulsion, we fancy that we are now impeded by the solid matter itself. But the very same is the opinion of the generality of mankind, with respect to the first obstruction. Why, therefore, may not the next be only another sphere of repulsion, which may only require a greater force than we can apply to overcome it, without disordering the arrangement of the constituent particles: but which may be overcome by a body moving with the amazing velocity of light. This scheme of the immateriality of matter, as it may be called, or rather the mutual penetration of matter, first occurred to Mr. Mitchell on reading Baxter on the Immateriality of the Soul. He found that this author's idea of matter was, that it consisted as it were of bricks cemented together with immaterial mortar. These bricks, if he would be consistent with his own reasoning, were again composed of less bricks, cemented likewise by an immaterial mortar; and so on, ad infinitum. This putting Mr. Mitchell upon the consideration of the several appearances of nature, he began to perceive that the bricks were so covered with this immaterial mortar, that if they had any existence at all, it could not possibly be perceived; every effect being produced, in nine instances of ten certainly, and probably in the tenth also, by this immaterial, spiritual, and penetrable mortar. Instead, therefore, of placing the world upon the giant, the giant upon the tortoise, and the tortoise upon he could not tell what, he placed the world at once upon itself.'

Other philosophers have supposed the powers both of gravitation and cohesion to be material; and to be only different actions of the ethereal fluid, or elementary fire. In support of this it is urged, that before we have recourse to a spiritual and immaterial power as the cause of any natural phenomenon, we ought to be well assured that there is no material substance with which we are acquainted, that is capable of producing such effects. In the present case, we are so far from having such assurance, that the contrary is manifest to our senses. One instance of this is in the experiment with the Magdeburg hemispheres. These are two hollow hemispheres of brass, exactly fitted to one another, so as to form one globe when joined together, without admitting any air at the joining. In this state, if the air within them is exhausted by a pump, they will cohere with such force, if they are five or six inches diameter, as to require a weight of some hundreds of pounds to separate them. The pressure of the atmosphere, we see, is in this case capable of producing a very strong cohesion; and if there is in nature any fluid more penetrating, as well as more powerful in its effects, than the air we breathe, it is possible that what is called the attraction of cohesion may somehow or other be an effect of the action of that fluid. Such a fluid as this is the element of fire. Its activity is such as to penetrate all bodies whatever; and, in the state in which it is commonly called fire, it acts according to the quantity of solid matter contained in the body. In this state it is capable of dissolving the strongest cohesions observed in nature: but whatever is capable of dissolving any cohesion must, necessarily, be endued with greater power than that by which the cohesion is caused. Fire, therefore, being able to dissolve cohesions, must also be capable of causing them, provided its power is exerted for that purpose. Nor will it seem at all strange that this fluid should act in two such opposite ways, when we consider the different appearances which it assumes. These are three, viz. fire or heat, in which it consumes, destroys, or dissolves; light, in which it seems deprived of all destructive or dissolvent power, and to be the most mild, quiet, and placid being in nature. The third is, when it becomes what is called the electric fluid; and then it attracts, repels, and moves bodies, in a vast variety of ways, without either burning or rendering them visible by its light. In this state it is not less powerful than in either of the other two; for a violent shock of electricity will displace and tear in pieces the most heavy and solid bodies. The seeming capricious nature of this fluid, however, probably renders it less suspected as the cause of cohesion, than it otherwise would be, were the attractions regular and permanent, which we observe it to occasion. But here we must observe, that the fluid has an existence in all bodies before the experiments are tried which makes its effects visible to us, and was acting in them according to its established laws. While acting in this manner it was perfectly invisible; and all we can do is to produce some little infringement of these regular laws, according to which it commonly acts. In some cases, however, the electrical attractions produced by art are found to be pretty perma-

nent and strong. Thus, Mr. Symmer, in some experiments with silk stockings, found their attraction so strong, that it required upwards of fifteen pounds weight to separate them from each other; and this attraction would continue for more than an hour. In plates of glass, too, he observed a remarkable cohesion when electrified. In the Philosophical Transactions for 1777 we find this hypothesis taken notice of, and, in some measure, adopted, by Mr. Henley. 'Some gentlemen,' says he, 'have supposed that the electric matter is the cause of the cohesion of the particles of bodies. If the electric matter be, as I suspect, a real elementary fire, inherent in all bodies, that opinion may probably be well founded; and perhaps the soldering of metals, and the cementation of iron, by fire, may be considered as strong proofs of the truth of their hypothesis.' On this hypothesis we must observe, that if the electric, or any other fluid, is supposed to be the cause of the attraction of cohesion universally, the particles of that fluid must be destitute of all cohesion between themselves; otherwise we should be at as great a loss to account for the cohesion of these particles, as for that of terrestrial matter. Philosophers, indeed, do not suppose any cohesion between the particles of the electric fluid themselves; it is generally believed that the particles of this fluid are repulsive of one another, though attracted by all other matter. If this is fact, we cannot suppose the electric fluid to be the cause of cohesion. The probability or improbability of this hypothesis, therefore, must greatly depend on its being ascertained whether the particles of the electric fluid do really repel one another, and attract all other kinds of matter, or not; but for this we must refer to the article ELECTRICITY.

COU'BIT, *v. a.* Lat. *cohibeo*. To restrain; to hinder.

COHO'BATE, *v. a.* To pour the distilled liquor upon the remaining matter, and distil it again. A returning any distilled liquor again upon what it was drawn from, or upon fresh ingredients of the same kind, to have it the more impregnated with their virtues.

Cohobation is the pouring the liquor distilled from anything back upon the remaining matter, and distilling it again.

Locke.

The juices of an animal body are, as they were, *cohabated*, being excreted, and admitted again into the blood with the fresh aliment. *Arbutnot on Aliments.*

COHOBATION, in chemistry, the returning the distilled liquor on the substance from which it was drawn. It is one of those operations which the ancient chemists practised with great patience and zeal, and which are now neglected. To make this operation easier, and to prevent the trouble of frequently changing the vessels, a particular kind of alembic was constructed, called a pelican, see diagram. This vessel was made in the form of a cucurbit, with an alembic head, but had two spouts communicating with the body. As the vapor rose up into the head, it was gradually condensed, and ran down the spouts into the body of the pelican, whence it was again distilled.

COHOEZ, or the falls of the Mohawk River, in New York, are a great natural curiosity. They are ten miles north of Albany, and about two and a-half above its mouth. The river, above the falls, is about 300 yards wide, and approaches them from the north-west, in a rapid current between high banks, and pours the whole body of its waters over a perpendicular rock of above forty feet high, which extends like a mill dam quite across the river. The banks immediately below the falls are 100 feet high. See **MOHAWK**.

COHORN (Memnon), a celebrated Dutch general and engineer, one of the most skilful writers on fortification that Europe ever produced. He fortified Bergen-op-Zoom, which is considered a masterpiece in the art. In 1692 he commanded Namur, the defences of which he constructed with the assistance of his celebrated rival, Vauban. He died at the Hague, in the seventy-fourth year of his age, July 1704.

CO'HORT, *n. s.* Lat. *cohors*. A troop of soldiers in the Roman armies, containing about 500 foot. In poetical language, a body of warriors.

The Romans levied as many *cohorts*, companies, and ensigns, from hence, as from any of their provinces. *Camden.*

The arch-angelic power prepared
For swift descent; with him the *cohort* bright
Of watchful cherubim. *Milton's Paradise Lost.*
Here, Churchill, not so prompt
To vaunt as light, his hardy *cohorts* joined
With Eugene. *Philip's Blenheim.*

COHORT, in Roman antiquity, a part of a Roman legion, containing about 600 men. There were ten cohorts in a legion, the first of which exceeded all the rest in dignity. When the army was ranged in order of battle, the first cohort took up the right of the first line; the third was in the centre of the first line of the legion, and the fifth on the left; the second between the first and third; and the fourth between the third and fifth; the five remaining cohorts formed a second division in their natural order.

COHORTATION, *n. s.* Lat. *cohortatio*. Encouragement by words; incitement.

COIF, *n. s.* } Fr. *ceiffe*; Arab. *kuchf*.
CO'IFED, *adj.* } a head-dress generally, ap-
CO'IFFURE, *n. s.* } plied especially to the ser-
geant's cap.

The judges of the four circuits in Wales, although they are not of the first magnitude, nor need be of the degree of the *coif*, yet are they considerable.

Bacon's Advice to Villiers.
No less a man than a brother of the *coif* began his
suit, before he had been a twelvemonth at the Tem-
ple. *Addison's Spectator.*

I am pleased with the *coiffure* now in fashion, and think it shows the good sense of the valuable part of the sex. *Id.*

COIGNE, *n. s.* An Irish term as it seems.

Fitz-Thomas of Desmond began that extortion of *coigne* and livery, and pay; that is, he and his army took horse-meat and man's-meat, and money, at pleasure. *Davies on Ireland.*

COIGNE, *n. s.* *Γωια*; Lat. *coigne*; Fr. *coigne*. A corner; a wedge used by printers; a die; a stamp used in coining money.

No jutting frieze,
Buttress, nor *coigne* of 'vantage, but this *bird*^d
Hath made his pendant bed.

Shakspeare's Macbeth.

See you yond' *coin* o' th' capitol, yond' corner
stone? *Id.*

COIL, *v. a. & n. s.* Fr. *cuiller*; Lat. *colligere*; from Gr. *κυκλω*. To wind up a rope in circles; to fold round in a ring, as a snake gathers up itself, and forms a compact circle of several folds. The substantive is used in a very different sense, and is derived by Dr. Johnson from the Germ. *kolleren*; which signifies tumult; turmoil; bustle; stir; hurry; confusion. It has also the primary sense of the verb.

Who was so firm, so constant, that this *coil*
Would not infect his reason.

Shakspeare's Tempest.

You, mistress, all this *coil* is 'long of you.

Shakspeare.

In that steep of death, what dreams may come,
When we have shuffled off this mortal *coil*,
Must gives us pause. *Id. Hamlet.*

The lurking particles of air, so expanding themselves, must necessarily plump out the sides of the bladder, and so keep them turgid, until the pressure of the air, that at first *coiled* them, be re-admitted to do the same thing again. *Boyle.*

From thy own smile I snatched a snake,
For there it *coiled* as in a brake. *Byron.*

COILING, on shipboard, implies a sort of serpentine winding of a cable or other rope, that it may occupy a small place in the ship. Each of the windings of this sort is called a *fake*; and one range of fakes upon the same are called a tier. There are generally from five to seven fakes in a tier; and three or four tiers in the whole length of a cable. This, however, depends upon the extent of the fakes. The smaller ropes employed about the sails are coiled upon cleats at sea, to prevent their being entangled amongst one another in traversing, contracting, or extending the sails.

COIMBETTORE, or **COIMBETOR**, **COIMATURA**, a small country in the south part of Hindostan, lying between 10° and 12° of N. lat. It is bounded on the north by Mysore, on the east by Kistnagherry and Salem, on the south by the district of Dindigul, and on the west by Cochin and part of Calicut. It has two divisions, North and South Coimbetoor; the latter suffered much in the late war, through the destruction of the reservoirs and aqueducts; but the former is well supplied with water, and in a high state of cultivation. On the north-west and south-west it borders on the lofty chain of the Ghauts, while directly westward it extends to the more level regions round Palicaudebery, which is the only break in the continuous line of those extensive mountains. Through this opening the river Paniany, the largest stream in this district, flows, on its way to the ocean. There are three principal towns in this country, Coimbetoor, Errood, and Carmour; the capital, which gives name to the province, is situated on the river Noyal, at the foot of the western Ghauts, in 77° 10' E. long., and 10° 55' N. lat. It is defended by a small citadel, and contains about 2,000 houses, with barracks for a regiment of

horse. Tippoo Saib built a handsome mosque in it, and sometimes resided here. In 1783 it was taken by the British, but restored the year following; in 1790 the British again took possession of it, after which its garrison under lieutenant Chalmers repulsed Tippoo in an attempt he made to storm it. It surrendered some time after to his general, Cammer ud Deen Khan, who treacherously made the garrison prisoners, and detained them till a general peace was concluded in 1792. Seven years after, it was added to the British dominions, together with the province.

Near the town of Coimbeoor the soil of the country is good, and generally free from rocks. Soil of every variety is cultivated for gardens, and the rent varies accordingly; but the price is greatly regulated by the depth at which water is found, being in some places eight cubits, and in others so low as eighteen. It is common, in many parts of the north, to water the gardens by machines, called *capity* and *yalam*, and thus a small portion of ground will support many persons, and yield a high rent to the land-holder, the crop is also less likely to fail for want of rain. The wet cultivation in this province may be about three per cent. of the whole cultivated surface. In the south the rice grounds on the banks of the Amaravati river are in full cultivation, and very extensive; but beyond that region the soil is rocky and poor, and very little enclosed. Muriatric and other salts, with nitrates, impregnate the earth throughout the whole province, and common salt and salt-petre are occasionally made. Nitre, indeed, seems to be ready formed, no addition of potash being necessary. The well water has, in many places, a flavor of these salts. Iron has been discovered in some parts of the country.

The inhabitants of Coimbeoor seem to rank very low in the scale of intellect, and the knowledge of the arts. The only one of these that has been carried to any perfection is that of

weaving. The Vaylalar, a numerous body of the Tamul race, are counted of the pure Sudra caste. In ancient times this district was called Kanjam; it was subjected to the rajahs of Mysore about 160 years since; but it now forms a collectorship under the presidency of Madras. It contains much uncultivated ground, and yields no permanent revenue.

COIMBRA, a large, handsome, and celebrated town of Portugal, anciently called Colimbria, standing on a hill, near the Mondego. It is the capital of the province of Beira, a bishop's see, and has a famous university, founded in 1290, and amply endowed. The cathedral and the fountains are magnificent, and the country around very pleasant, abounding in vineyards, olive-trees, and fruits. Its population is about 12,000. The Mondego is here crossed by an elegant stone bridge, with a double row of arches, but the town is, in the interior, narrow, crowded, ill-paved, and dirty, and in some places the streets are very steep. The university is now the only establishment of the kind in Portugal. It consists of eighteen colleges, with very ample funds. The course of study is divided into six branches, viz. theology, taught by eight professors; canon law, by nine; civil law, by eight; medicine, by six; mathematics, by four; and philosophy, by four. The session commences in October, and closes in May; and the average number of students is 800. Coimbra is of great antiquity, and was formerly the residence of the kings of Portugal, several of whose tombs it contains. It was fortified at an early period, and has sustained many sieges. The ancient walls and towers still remain. It suffered considerable damage from the earthquake which destroyed Lisbon in 1755, and a number of French soldiers, belonging to the rear of Massena's army, were made prisoners here by lord Wellington in October 1810, after the action of Busaco. Sixty miles S. S. E. of Oporto, and N. N. E. of Lisbon.

C O I N S.

COIN, *n. s. & v. a.* } See COINER. Money
COIN'AGE, *n. s.* } legally made. Payment
COINER, *n. s.* } of any kind. The verb
is derived from the noun, but has a greater variety of applications. To mint or stamp metals for money is its primary sense. But it likewise signifies to invent; to forge in a bad sense; to produce; to give existence to; to impress with an image relating to the mind.

But if that they were put to swiche assays,
The gold of hem hath now so bad allayes,
With bras, that though the *coine* be faire at eye,
It wolde rather brast atwo than plie.

Chaucer's Canterbury Tales.

Dyonisius, a Greek *coiner* of etymologies, is commended by Athenæus.

C Camden's Remains.

They cannot touch me for *coining*: I am the king.

Shakspeare.

My father was I know not where

When I was stamp't: some *coiner* with his tools

Made me a counterfeit. *Id. Cymbeline.*

Vol. VI.

My King's

Coin words till their decay, against those measures,
Which we disdain should tetter us. *Id. Coriolanus.*

This is the *coinage* of your brain;

This bodiless creation ecstasy

Is very cunning in.

Id. Hamlet.

You have made your holy hat to be stamped on the king's *coin*.

Id. Henry VIII.

He gave Demetrius a good sum of gold in ready *coin*, which Menæceus had bequeathed.

Sidney.

And truly to support that charge,

He had supplies as vast and large,

For he could *coin* or counterfeit,

New words with little or no wit.

Hudibras.

Never *coin* a formal lye on't,

To make the knight o'ercome the giant. *Id.*

These motives induced Virgil to *coin* his fable.

Dryden.

Unnecessary *coinage* as well as unnecessary revival of words, runs into affectation; a fault to be avoided on either hand.

Id. Juvenal. Dedication.

This is conceived to be a *coinage* of some Jews, in derision of Christians, who first began that portrait.

Bracton.

The loss of present advantage to flesh and blood, is repeated in another coin. *Hammond's Fundamentals.*

I cannot tell how the poets will succeed in the expedition of *coins*, to which they are generally very great strangers. *Artis v.*

It is easy to find designs that never entered into the thoughts of the sculptor or the *coiner*. *Id. on Medals.*

She now contracts her vast design.

And all her triumphs shrink into a coin.

P. Pe.

The care of the *coinage* was committed to the inferior magistrates, and I don't find that they had a public trial, as we solemnly praise in this country. *Abulobac.*

COIN, in commerce, is a metallic species of money. The barter of one species of goods, or produce, for another, was doubtless the first step in commerce; but Aristotle (*Pol. lib. i. c. 6.*) very well explains the early introduction of a valuable medium of exchange. 'All useful things,' says he, 'could not, without great difficulty, be carried about from place to place, it was resolved, therefore, by common consent, that in bartering commodities, they should reciprocally give and receive some substance, which, being in its nature applicable to the purposes of life, might, at the same time, be easily transported. Cattle was an early medium of this kind; hence some have derived the Latin word pecunia from pecus a herd; and in Homer we find Glaucus's armour valued at 100 oxen, and that of Diomedes at ten.' The patriarch Abraham's purchase of his family burying place is the earliest commercial transaction on record, and this he requests to buy for 'as much money as it is worth, and he is said to have paid or weighed for it 400 shekels of silver, current with the merchant.' This was, no doubt silver in convenient pieces for 𐤁𐤁𐤁𐤁 passing to, or with the merchant. 'We have an order of Lycurgus' on record that iron money only should be used in Sparta; iron bars quenched in vinegar are mentioned as the Lacedæmonian money on other occasions; and the ancient Britons were found at the period of the Roman invasion using this metal as well as tin for the same purpose, in the shape of plates and rings. Seneca speaks of an ancient stamped money of leather, *odium firma publicæ impressum* an expedient used by Frederic II. at the siege of Milan; and, according to some traditions among ourselves, in the time of the barons' wars. In 1660 king John of France, having agreed to pay our Edward III. for the ransom of his person 200,000 of gold crowns, was reduced to the necessity of paying for the necessaries of his household in leather money, in the middle of which was a little nail of silver. Pastel-coin was coined by the Hollanders in great quantities in the year 1574. Numa Pompilius circulated money of wood and leather, and during the whole period of their early monarchy the Romans do not appear to have used any stamped metallic currency. Wherever commerce obtained, the metals uniformly seem to have been adopted as money for their portability, neatness, durability, and universality; there is reason to believe that they were very early used in Egypt,

and, as we have seen, in Asia; that thence they were introduced into Carthage and Greece, and brought from Greece to Rome. Pliny states that silver was first coined at Rome, A. U. C. 480, and gold about the year 640. The first valuation of Roman money was by the 'libra gravis æris,' or pound of heavy brass.

Mr. Turner (*History of the Anglo-Saxons, v. ii.*) has a curious chapter on the coins of our Saxon ancestors. He ascertains that they often reckoned the whole amount of their money by pennies, as the French now do theirs by livres; and that there were larger pennies (*mætra peninca*, five of which made one shilling; and smaller of twelve to the shilling. The mancus, frequently mentioned, was thirty large pennies, or six shillings. The mark, ten shillings.

The money first mentioned, in any legal document extant, consists of shillings and scotta, *yoæc*, part or division, by which our author thinks that a definite piece of metal in an uncoined state is meant; and regards these two as the general names of the Saxon money before the Roman and French ecclesiastics taught them the art of coinage. Various charters mention pennies, mancusa (of thirty pennies, the larger ones, each, pounds, shillings, and seldi, which last is sometimes said to be of gold, and sometimes of silver; on some occasions the term seems to be used as synonymous with scillinga. The pound was an imaginary value of money, or a mode of computing it, and not a coin.

'As no Anglo-Saxon gold coins have reached modern times,' says this able writer, 'though of their silver coinage we have numerous specimens, it is presumed by antiquaries that none were ever made, yet it is certain that they had plenty of gold, and it perpetually formed the medium of their purchases and gifts. My belief is, that gold was used in the concerns of life, in an uncoined state, and to such a species of gold money I would refer such passages as these fifty 'mancussa asdenes gold,' 'sexus viginti marcarum auripondis, appensuram novem librarum purissimi auri juxta marcum penitus Normannorum,' 'eighty mancussa auri purissimi et sex pondus electi argenti, duo uncias auri.' I think that silver also was sometimes passed in an uncoined state, from such intimations as these 'two pund mere kwites seofthes,' and the above-mentioned 'sex pondus electi argenti.' The expressions that precede Domesday-book imply, in my apprehension, these two species of money, the coined and the uncoined. Seventy libras pensatas, like two uncias auri, are obviously money by weight. But money ad numeram, or arsuram, interpret to be coined money; also the pund by genale. The phrases, sex libras ad pensum et arsuram et triginta libras arsas et pensatas, appear to me express the indicated weight of coined money. The words arsas and arsuram I understand to allude to the assay of coin in the mint.

He is inclined to think, also, that the monies was like the pund, a weight, rather than a coin; and says in a note that he is assured on high antiquarian authority, 'that even the scillinga was a nominal coin; as no silver coin of that value has been found which can be traced to Saxon times.'

Coined money appears soon after the Anglo-

Saxon invasion of England, and throughout the octarchy; but none can be traced in their history before that event. From the laws of Ethelstan, it appears that the places at which public mints were established were (Wilkin's Leg. Anglo-Saxons p. 59) 'at Canterbury seven myntras,' four belonging to the king, two to the bishop, and one to the abbot. At Rochester three, two of the king's, and one the bishop's. At London eight, at Winchester six, at Lewis two, at Hastings one, at Chichester one, and two at Hampton; Wareham, Exeter, and Shaftesbury, respectively. From Domesday-book, they also appear to have been distributed throughout all the large towns. It need hardly be added that these were evidently the small hammer mints first used, and not establishments quite of equal magnitude with that over which Mr. Pole now so ably presides.

William the Conqueror seems to have adopted the plan of his coinage from France and the establishments of Charlemagne; he retained the Saxon pound weight or Moneger's pound as it was now called, and which is ascertained to have been a sixteenth, or 5400 grains less than the troy pound; and coined from it twenty shillings which made twenty-one one-third pounds troy. It was not until the reign of Henry VIII. (1526) that the troy pound was used at the royal mint. This we see was an increase of the Moneger's pound, and it continued to be increased in successive reigns until the eighteenth of Charles II., when it was fixed at sixty-two shillings, and so continued until the recent alterations in 1816, which made it sixty-six shillings.

The word sterling was originally applied both to the silver penny, and to the penny-weight, which was minted with a deep cross. When this was broken across it was called the *half-penny*, and when into four parts, the *fourth-thing*, or farthing. Silver four-pennies were also coined, and called *greats* or groats. There were also distinct silver half-pence and farthings, but no shillings coined, according to Dr. Kelly, until the year 1504, in Henry VII. reign; and no copper money until 1665, in the reign of Charles II.

The first gold coins on record were struck by Henry III. in the year 1257. and were called *gold pennies*, weighing as much as two silver pence, and passing for twenty pence. Snelling says, this coinage took place through the king's 'necessity,' and that the city of London remonstrated against the measure. Our next gold coinage was that of the *florin* (from Florence, where a similar piece seems to have been first struck), in 1354, called also abroad the *guilder*, or golden piece, and containing twenty-three carats, three grains and a half of fine gold, with half a grain of alloy. This was called the old standard, and continued until the minting of crown pieces in 1527, when the new standard, called at first crown gold, was introduced.

It was enacted in 1266, 3 Edw. 51, 'that an English penny, called a sterling, round and without clippers, shall weigh thirty-two wheat corns from the midst of the ear, and twenty pence to make one ounce, and twelve ounces one pound;' 'eight pounds, it is added, do make one gallon of wine, and eight gallons of wine do make a

London bushel, which is the eighth part of a quarter.

Of the old gold standard, the principal coins were *nobles*, of 6s. 8d. value; *half* and *quarter* or farthing nobles, as they were also called; *marks*, of 13s. 4d. value; *angels* of 10s. and *sovereigns* of 20s. each. The last were first minted in Henry VII. reign, and frequently altered afterwards, until that of James I., by whom they were fixed at twenty-two carats, fine. The sovereigns of this reign were at first called *unites*, and thirty-three pieces and a half were struck from the troy.

Charles II. first minted *guineas* (so called from that part of Africa from which the gold used happened at this time to be brought), and forty-four pieces and a half were yielded from a pound troy. This coin varied in current value from twenty to thirty shillings, until the mint was placed under the care of Sir Isaac Newton; who in 1717 induced the government to fix it at twenty-one shillings. In 1816 took place the new gold coinage of sovereigns at the proper proportion to this guinea, i. e. of 46 $\frac{2}{3}$ pieces to the pound troy.

Seignorage was irregularly charged at the royal mint for both gold and silver coins, until the year 1666, when it was enacted, that all persons bringing in either of the previous metals to be coined, should receive back the full value free of expense: a law still in force as to gold, but the silver coinage is now wholly managed by government; and since 1816, gold has become the sole standard measure of value without any limitation as to the amount that may be legally tendered, but silver coin is only a legal tender to the amount of forty shillings.

Queen Elizabeth seems to have contemplated some reform in our coinage; she ordered the *avoirdupois* pound to be placed in the exchequer as a standard, and that a copy of the troy pound of goldsmith's hall should be accurately made and deposited in the exchequer, but no practical measure resulted from this.

In the reign of George II., 1753, the first important enquiry of modern times respecting our coinage, was instituted by government. Mr. Bird, a distinguished optician and instrument maker, and Mr. Harris, the king's assay master of the mint, were examined, with several other able mechanics, by a committee of the House of Commons, as to the standards of English weights and measures. Their report demonstrates the great care and ability employed in the proceedings. Speaking of the relative claims of the pound troy and the pound *avoirdupois*, as a standard weight, they prefer the former 'Because' as the report states, 'it is the weight best known to our law; that which has been longest in use; that by which our coins are measured; that which is best known to the rest of the world; that to which our learned countrymen have referred, and compared ancient and modern weights; the weight which hath been subdivided into the smallest parts. On the other hand, the *avoirdupois* weight is of doubtful authority; and, though unfit to be made a standard, yet the frequent use of it renders it necessary to ascertain and declare how many ounces, pennyweights,

and grains, troy, the pound avoirdupois ought to weigh.'

This committee caused the inaccurate divisions of the mint standard to be corrected: the following is their account of this important operation: 'Your committee thought it necessary, in the first place, to obtain, with the utmost possible exactness, standard weights of the several parts of the pound troy, in order that from thence such other combinations, or proportions, of weight might be formed, as the business or necessities of the subject should require. And Mr. Harris was employed to make these several parts, who accordingly did so, with great skill and attention, by a very curious and accurate apparatus contrived by Mr. Bird. It was adapted to five different beams, which ascertained the weights from twelve ounces, or one pound, down to a grain inclusive; and that with so great exactness, as to discern any error in the pound weight to the 230.400th part of the weight, and to the 2000th part of a single grain. By these beams, the several parts of the standard pound were examined and adjusted by Mr. Harris, in the presence of your committee, and were found to be what their denominations import. These several parts were tried in every progressive combination necessary to discover their proportions to each other; and appeared so exact, that no greater degree of correctness could, in the nature of the thing, be expected.'

An authentic copy of this standard pound was delivered to the house of commons, and another to the king's assay master of the mint, in whose office it is still carefully preserved, with Mr. Bird's weighing apparatus. With this apparatus, the late comparisons of foreign standards have been made at the mint; but, it should be observed, that certain standards, which were too heavy for this beam, were weighed by a new hydrostatic balance of great accuracy, invented by John Barton, esq. deputy-comptroller of the mint. Before the general comparison was begun, it was deemed proper to compare the parliamentary pound with the exchequer standard; and, for this purpose, the latter was taken to the mint, by an order from the chancellor of the exchequer, where it was found to be one grain and a-half lighter than the parliamentary pound; and its divisions proved to be still more inaccurate. It should be observed, that lord Carysfort's committee intended to correct this standard, as appears by their report; but in 1760, before their plans were completed, parliament was dissolved, and thus ended their useful labors. Since that period no alteration has been made in the standards, though much attention has been paid to the subject, both in and out of parliament, especially since the adoption of the metrical system in France.

The comparison alluded to between the English standard weights took place in the latter part of the year 1818, in the presence of the principal officers of the mint and the chamberlain of the exchequer. In the same year, at the suggestion of Dr. Kelly, of Finsbury-square, the lords of his majesty's privy council for coins, recommended the following letter to be despatched,

through the foreign office, to his majesty's consuls abroad:—

COPY OF LORD CASTLEREAGH'S CIRCULAR TO
THE BRITISH CONSULS ABROAD.

'Foreign Office, March 10th, 1818.

'SIR,

'His majesty's government, being desirous of obtaining every information as to the standards in use, for the various weights and measures in foreign countries, with a view to ascertain their relative bearings to those in use here, for the benefit of the commercial interests of this country:

'I am to desire, that you will use your endeavour to procure, with as little delay as may be, two sets of models, being counterparts in every respect, of the standard pound or mark used at your place of residence for weighing gold and silver, and also of other lesser weights used for that purpose.

'If, in any place within your consulate, the standard pound or mark, with its lesser weights, used for weighing gold or silver, should differ from those in use at your place of residence, you will procure also two sets of the weights so differing.

'You will have the accuracy of all these weights regularly attested by the proper authorities.

'You will pack up carefully, and separately, these two sets of weights complete: and you will send them to me by separate conveyances, accompanying each set by an explanatory letter, written in duplicate. In that letter you will give a list and description of the weights sent.

'You will state the difference and proportion between the pound which is used for weighing gold and silver, and that pound used for ordinary articles, which is generally known by the name of the commercial pound.

'You will state the contents of the principal measure, used at your place of residence, and at other places within your consulate, for the measure of corn, and of the principal measure for wine, and also of their lesser measures.

'You will be so good as to describe the contents of these measures, by stating how many cubic inches of the place they contain, or how many English gallons, or how many French litres.

'You will add in your letter such other information as you can collect, or may be in possession of, for throwing light upon the general subject of this instruction.

'You will keep an account of the expense to which you may be subjected in the execution of this instruction, and you will send such account, made out in duplicate, in a letter marked separate, which letter and account may accompany the weights, and the dispatch explanatory of the subject.

'CASTLEREAGH.

'To —, his majesty's consul at —.'

These orders were, in due time, executed in a very correct and satisfactory manner, and the packages transmitted, contained, besides the re-

quired standards, very ample specifications of the divisions of weights and measures. They were first delivered at the foreign office, and thence sent by Joseph Planta, esq. under secretary of state, to the royal mint, through the medium of the board of trade. In the beginning of the year 1820 the intended comparisons were carried into effect. These experiments were made by Robert Bingley, esq. who had assayed the coins, as before stated, and who, on every occasion, evinced the most zealous attention to scientific accuracy.

Dr. Kelly attended this course of experiments at the mint; and, having registered the results, obtained permission to remove the standards to his house, with a view of having the comparisons repeated; and, as a farther means of verification, to compare the subordinate weights or divisions,

the *units* only having been compared at the mint. This second course of experiments was made with a fine balance, recently constructed by Mr. Troughton for the London institution, and with attested standards, both French and English. These comparisons, which were repeated by several competent persons, proved highly satisfactory as corresponding with the mint experiments.

Dr. Kelly has constructed, from the experiments, the various tables of coins which we shall now offer to the reader; and for the use of which the proprietor of this work has been very happy to transmit to that gentleman a considerable remuneration. We have had the pleasure of inspecting some of those contributions of our consuls, and of a liberal and powerful government, to the pursuits of science, in Finsbury-square

TABLE I.

AN HISTORICAL TABLE OF ENGLISH COINS,

Shewing the alterations they have undergone from the reign of William the Conqueror to that of George IV., with respect both to their weight and fineness. Also, a statement of the comparative value of gold and silver, at different periods.

Date.	Reign.	SILVER.			GOLD.			Comparative Value of fine Gold & Silver.

1604	2 James I.	— —	3	2	0	22	0	33	10	0	1 — 12,109
1626	2 Charles I. .	— —	3	2	0	— —	— —	41	0	0	1 — 13,346
1666	18 Charles II.	— —	3	2	0	— —	— —	44	10	0	1 — 14,485
1717	3 George I. .	— —	3	2	0	— —	— —	46	14	6	1 — 15,209
1816	56 George III.	— —	3	6	0	— —	— —	46	14	6	1 — 14,287
1821	2 George IV.	— —	3	6	0	— —	— —	46	14	6	1 — 14,287

By the above table, it appears, that silver coins have been diminished in value, during the last 500 years in the ratio of ninety-nine to thirty-two, and gold coins nearly as three and a-half to one. It may be remarked that, within the same period, the silver coins of France and Spain have been debased in the ratio of about seventeen to one.

TABLE II.—NEW TABLE OF GOLD COINS.

Containing the Assays, WEIGHTS, and VALUES of the principal GOLD COINS of all Countries, computed according to the Mint Price of Gold in England, and from Assays made both at London and Paris, which have been found to verify each other.

The London Assays have been made by Robert Bingley, Esq. F.R.S. the King's Assay Master of the Mint, and those at Paris by Pierre Frederic Bonneville, Essayeur du Commerce, as published in his elaborate work on the Coins of all Nations.

Golden of the Dutch, E. I. Comp. 1820	W. 0	7	6	22	6	10 6 149.4	

In order to show the principles on which the foregoing tables are calculated, it may be proper first to explain the manner by which the value of any coin may be determined when its weight and fineness are known. For this purpose the quantity of standard gold and silver contained in it must be first found; and then its sterling value may be ascertained from the Mint-price of the standard ounce.

GOLD COINS—What is the sterling value of a French Double Louis d'or, the Report (per table, page 131,) being as follows:—weight 9 dwt. 20 gr. Assay W. 1½ gr. that is, 0 car. 1½ gr. worse than English standard?

			car.	gr.		
			From 22	0	the fineness of standard gold,	
			Subtract 0	1½		
			<hr/>			
			21	2½		
Then, as	22	:	21	2½	::	9
	4	:	4		::	24
	<hr/>		<hr/>			
	88		86½			236
						86,5
			<hr/>			(24
	88)	20414,0	(232	grains nearly.		
		176	216			
		<hr/>				
			281	&c.	9 dwt. 16 gr.	

Again, as	1	:	3	17	10½	::	9	16	::	1	17	7½	the value of the piece in sterling.
	20		20				24						
	<hr/>		<hr/>				<hr/>						
	20		77				232						
	24		12				934½						
	<hr/>		<hr/>				<hr/>						
	480		934½		48,0)	21680,4	(4516						
						192							
						<hr/>							
						2,0)	37	7½					
						<hr/>							
						4	£1	17s.	7½	d.			
						<hr/>							
						&c.							

The foregoing calculations may be considerably abridged by using a constant decimal as a multiplier. The following is a general rule for gold coins.

Multiply the carat grains in the fineness by the troy grains in the weight, and again multiply this product by 92182; cut off nine decimals, which will give the answer in pounds and decimals of a pound sterling.

Thus, in the foregoing question of the Louis d'or,

$$86,5 \times 236 = 20414$$

$$\underline{\hspace{1.5cm}} 92182$$

$$1,881803348$$

$$\underline{\hspace{1.5cm}} 20$$

$$17,636$$

$$\underline{\hspace{1.5cm}} 12$$

&c.

Answer. £1. 17s. 7½d.

To find the contents of pure gold in the above coin, say,

	car.	car.	gr.	dwt.	gr.	gr.
As 24	:	21	2½	::	9	20
						212,6

Or, the contents in pure gold may be found by multiplying the standard weight by 11, and dividing by 12; and standard gold may be reduced to pure by reversing this operation.

SILVER COINS.—What is the value of a Spanish Dollar, the Report (per table, page 133,) being as follows:—weight, 17 dwt. 8 gr. Assay W. 8 dwt. that is, 0 oz. 8 dwt. worse than English standard?

	oz.	dwt.
From 11	2	the fineness of standard silver,
Subtract 0	8	
	<hr/>	
	0	1

	oz. dwt.	oz. dwt.	::	dwt. gr.	dwt. gr.	
Then, as	11 2	10 14	::	17 8	16 17	the standard silver contained in the Dollar.
	20	20		24		
	222	214		416		
				214		
				(24		
				222)89024(401		
				888		
				16 dwt. 17 gr.		
				224 &c.		

	oz.	gr.	s. d.	::	dwt. gr.	s. d.	
Again, as	1	480	5 2	::	16 17	4 3 $\frac{3}{4}$	the value of the Dollar in sterling.
			12		24		
			62		401		
					62		
					(12		
					48,0)2486,2)51,8		
					2400		
					4s. 3 $\frac{3}{4}$ d.		
					86 &c.		

The foregoing operation may be thus abridged:—

RULE FOR SILVER COINS—Multiply the carat grains in the fineness by the troy grams in the weight, and again multiply this product by 5818; cut of seven decimals, which will give the answer in pence and decimals of a penny sterling.

Thus, in the foregoing question of the Spanish Dollar,

$$\begin{array}{r}
 214 \times 416 = 89024 \\
 \underline{\hspace{1.5cm}} \\
 \hspace{1.2cm} 5818 \\
 \underline{\hspace{1.5cm}} \\
 51,7941632 \\
 \hspace{1.2cm} 4 \\
 \underline{\hspace{1.5cm}} \\
 3,1766528 \\
 \text{Answer. } 4s. 3\frac{3}{4}d.
 \end{array}$$

To find the contents of the Spanish Dollar in pure silver, say—

$$\text{As } 12 \text{ oz. } : 10 \text{ dwt. } :: 17 \text{ 8 gr. } : 370,9 \text{ gr.}$$

Or the contents in pure silver may be found by multiplying the standard weight by 37, and dividing by 40; and, on the contrary, multiplying the contents in pure silver by 40, and dividing by 37, will give the standard weight.

The precious metals in England are mostly bought and sold at so much per ounce standard. It therefore becomes necessary to determine the standard weight; and this must be calculated from the Assay Master's Report of weight and fineness.

But it may be useful first to explain the characters which are generally used in these Reports.

ASSAYER'S MARKS.

/	is	1 Dwt.	and occasionally as 1 oz.
ij	—	2	—
2	—	5	—
e	—	10	—
e2	—	15	—
e2ij	—	18	—
e/e	—	19	—
ob	Obulus	$\frac{1}{2}$	—

The common method of finding the value of small quantities of gold and silver is by alloying from the Assay Master's Report, at the rate of 4s. per carat, better or worse, in every ounce weight of gold; and at the rate of 6d. per ounce, better or worse, in every ounce weight of silver. But when silver is more than 10 dwt. worse, an allowance of 2d. per ounce must be made for refining.

THE FOLLOWING ARE THE SCALES OF ALLOWANCE.

Scale for Gold. 1 car. (4s.) <hr style="width: 20%; margin: 0 auto;"/> 1 gr. (1s.) <hr style="width: 20%; margin: 0 auto;"/> $\frac{1}{2}$ gr. (6d.) <hr style="width: 20%; margin: 0 auto;"/> $\frac{1}{4}$ gr. (3d.) <hr style="width: 20%; margin: 0 auto;"/>	Scale for Silver. 1 oz. (6d.) <hr style="width: 20%; margin: 0 auto;"/> 15 dwt. (4½d.) <hr style="width: 20%; margin: 0 auto;"/> 10 dwt. (3d.) <hr style="width: 20%; margin: 0 auto;"/> 5 dwt. 1½d. <hr style="width: 20%; margin: 0 auto;"/> 2¾ dwt. (¾d.) <hr style="width: 20%; margin: 0 auto;"/>
---	--

Thus, to find the value of 2 oz. of gold B. 1 car. 1 gr. at £4. per oz.—To £8. (for 2 oz.) add 10s. for better, which gives the value £8. 10s.—And to find the value of 12 oz. of silver, W. 10 dwts. at 5s. 6d. per oz. From £3. 6s. (for 12 oz.) subtract 3s. for worse, which gives the value £3. 3s. We submit finally

I.—RULES FOR STANDARDING GOLD.

As 22 carats are to the Assay, or Report of fineness, so is the gross weight to the quantity that is to be added or subtracted from this gross weight, according as the report is better or worse. If better, the additional quantity is called (by the trade) Betterness, and if worse, the subtractive quantity is called Worseness.

Example—How much standard gold is there in an ingot of the following Report, B. 1 car. 3½ grains. Weight, 67 oz. 15 dwt. 8 gr.?

As 22	:	1 3½	::	67 15 8	Or thus, as 22	:	23 3½	::	67 15 8
4	:	4		20					73 10 20
<hr style="width: 20%; margin: 0 auto;"/>									
38	:	7		1355					
4	:	4		24					
<hr style="width: 20%; margin: 0 auto;"/>									
352	:	30		32528 × 30 ÷ 352 = 2772 gr. = 5 oz. 15 dwt. 12 gr.					

oz. dwt. gr.
To 67 15 8 Gross Weight
Add 5 15 12 Betterness
<hr style="width: 50%; margin: 0 auto;"/>
73 10 20 Standard.

The following method for standarding gold may be generally used with advantage:—

		oz. dwt. gr.					
2 gr. = ½		67 15 8	Gross Weight B. or W.	1 car. 3½ gr			
1 = ½		33 17 16					
1 = ½		16 18 20					
½ = ½		8 9 10					
		<hr style="width: 20%; margin: 0 auto;"/>					
		20127 1 6	} Divided by 22				
		<hr style="width: 20%; margin: 0 auto;"/>					
		1163 10 15					
		<hr style="width: 20%; margin: 0 auto;"/>					
		5 15 12	Betterness or Worseness, as above.				

II. RULES FOR STANDARDING SILVER.

As 11 oz. 2 dwt. to the assay, so is the gross weight to the quantity which is to be added or subtracted, according as the report is B. or W.

Example—In 287 oz. of silver, W. 12½ dwt., how much standard?

As 11 2	:	12½	::	287	Or thus, as 11 2	:	10 9½
	:	20		20		:	287
<hr style="width: 20%; margin: 0 auto;"/>							
	:	222		2840		:	270 16 20
<hr style="width: 20%; margin: 0 auto;"/>							
				12½			
<hr style="width: 20%; margin: 0 auto;"/>							
				222)71750(323 dwt. 4 gr. = 16 oz. 3 dwt. 4 gr.			
				oz. dwt. gr.			
				From 287 0 0 Gross Weight			
				Subtract 16 3 4 Worseness			
<hr style="width: 20%; margin: 0 auto;"/>				270 16 20 Standard.			

From the last example, the reason of the following rule for standarding silver is obvious:

Multiply half the weight in ounces by the assay in pennyweights, and divide the product by 111, the quotient will be the letterness or worseness in ounces.

Example—How much standard silver in 160 ounces of B. 18½ dwt. ?

Half weight 80
18½

oz. dwt. gr.
111) 1480 (13 6 16
111
370 &c.

oz. dwt. gr.
No 160 0 0 Gross
Add 13 6 16 Betterness
173 6 16 Standard

It should be observed that there are tables constructed, and sometimes used, for standarding gold and silver, as may be seen in Postlethwayt's Dictionary of Commerce, vol. 1, page 388 to 398; but, from the simplicity and conciseness of the foregoing examples, it is manifest that such tables cannot much shorten the operation, though they may serve to check or prove the calculation.

III. RULES FOR CONVERTING THE FOREGOING TABLES OF COINS INTO FRENCH DENOMINATIONS.

To reduce English gold coin into Francs, and the contrary.

RULE—Multiply the number of Pence by .105: and the number of Francs by .9525.

Example—How many Francs in a Sovereign ?

Here 240d. × .105 = 25 Francs 20 Centimes.

And again, 25 Francs 20 Centimes × .9525 = 240 Pence.

To reduce English sterling silver into Francs, and the contrary.

RULE—Multiply the number of Pence by .103: and the number of Francs by 9.709.

Example—How many Francs in 240 Pence, silver value ?

240 × .103 = 24 Francs 72 Centimes;

And this number × 9.709 = 240 Pence.

The foregoing results are the Pars. very nearly, in gold and silver value.

To bring English grains into Grammes, and the contrary.

RULE—Multiply the number of Grains by .064792; and the number of Grammes by 15.434

Example—How many Grammes in a Sovereign, weighing 113.1 English grains of pure gold ?

Answer, 7 Grammes 328 Decigrammes, nearly; and this number, multiplied by 15,434, equals 113.1 grains.

By the application of the above rules, all the foregoing Tables of Coins may be converted into French denominations, except the first column, which contains the Assay, and which is thus reduced:—

RULE FOR GOLD COINS—Make the Assay Report the numerator, and 24 the denominator, and this vulgar fraction, reduced to three places of decimals, will give the Millimes, according to the French expression.

Example—To convert English standard gold into Millimes.

Thus, $\frac{22}{24} = 91\bar{6}$ Millimes. If the gold be 1 carat 2 grains worse than standard.

	car. gr.	
	22 0	
	1 2	
	—	
	20 2	24
	4	4
	—	—
Carat grains 82		96

then $\frac{82}{96} = 854$ Millimes.

Millimes are reduced to carats by multiplying by 24 and cutting off three decimals.

FOR SILVER COINS—To reduce English Assay Reports of silver into French Reports, or Millimes.

RULE—Make the number of pennyweights in the Assay Report the numerator, and 240 the denominator, and this reduced to a decimal fraction of three places gives the Millimes.

Example—To reduce English standard silver into Millimes.

	dwt. gr.
	11 2
	20
	—
	222
	— = $\frac{222}{240} = 925$ Millimes.
	240

To reduce Millimes into English Assay Reports of silver.

RULE—Multiply by 240, and cut off three decimals. Thus, 891 Millimes × 240 = 211 = 10 dwt 14 grs., and this subtracted from 11 dwt. 2 gr. gives 8 dwt. worse than English standard.

Dr. Kelly's Explication of the Coins of France presents a singular picture of the modern changes of that country. We subjoin it for this, its curious political bearing. He gives a very able and detailed explanation of the same kind respecting all the modern coins of the world, in his *Cambist* 2 vols. 4to. London, 1826.

FRANCE.

GOLD COINS.

The *LOUIS*—Head of the reigning King, with his name and title: thus,

LUD. XVI. D. G. FR. ET NAV. REX.

that is, Ludovicus XVI. Dei Gratia, Franciæ et Navaræ Rex,

Louis XVI. by the Grace of God, King of France and Navarre.

Reverse, the arms of France and Navarre, with a crown over them. On the Pieces coined before 1786 there are two distinct shields; and, on those coined since 1786, a double shield; legend,

CHRS. REGN. VINC. IMPER.

that is, Christu regnat, vincit, imperat,

Christ reigns, conquers, governs;

under the arms is a letter, by which the mint where the piece was coined is known. The Double and Half Louis bear the same impressions.

The Pieces struck in the year 1791 have on the obverse the head of the King, with the title,

LOUIS XVI. ROI DES FRANCOIS.

Louis XVI. King of the French.

and, on the reverse, the Genius of France writing the Constitution on a tablet resting on a pillar, with a cock on one side, and on the other the fasces and cap of Liberty, with the legend,

REGNE DE LA LOI,

Reign of the Law;

and at the bottom,

L'AN 4 DE LA LIBERTE,

The year 4 of Liberty.

The Piece of 1793 has, instead of the head, a crown of oak-leaves, containing the words 24 LIVRES; legend,

REPUBLIQUE FRANÇOISE L'AN II.

French Republic, the year 2.

Reverse, as on the Louis of 1791, except that the date is in figures only.

The Piece of 40 FRANCS, 1802—Head of Bonaparte; legend,

BONAPARTE PREMIER CONSUL.

Bonaparte, first Consul.

Reverse, a wreath of laurel, containing the words 40 FRANCS; legend,

REPUBLIQUE FRANÇOISE AN. XI.

and, round the edge of the piece,

DIEU PROTEGE LA FRANCE,

God protect France.

In 1804, on Bonaparte's being declared Emperor, the words round the head were altered to NAPOLEON EMPEREUR. The Piece of 20 Francs bears the same impressions, except the figures that mark its value.

The Piece of 40 FRANCS, 1818—Head of the King, with name and title, thus:

LOUIS XVIII. ROI DE FRANCE.

Reverse, arms of France, and 40 F. within two branches of laurel. Round the edge of the piece,

DOMINE SALVUM FAC REGEM.

O Lord, save the King

SILVER COINS.

The *ECU* of 6 LIVRES—Head of the reigning King, with name and title, as on the Louis. Reverse, the arms of France, between two laurel branches; legend,

SIT NOMEN DOMINI BENEDICTUM,

Blessed be the name of the Lord.

and a letter denoting the place where the piece was coined. Round the edge are the words

DOMINE SALVUM FAC REGEM,

as on the 40 Franc Piece. The Ecu of three Livres, the Pieces of 24, 12, and 6 Sous, all bear the same impressions, except that the three last mentioned coins have no motto round the edge.

The *ECU* of 1791—Head of the King; legend,

LOUIS XVI. ROI DES FRANCOIS.

Reverse, the Genius of France, &c. as on the Louis of the same period. Round the edge,

LA NATION LA LOI ET LE ROI,

The nation, the law, and the King.

The Pieces of 15 and 30 Sols, coined at the same period, bear the same impressions, except that, instead of the fasces and cock, their value is marked, and that the motto round the edge is omitted.

The 6 LIVRE Piece of the Republic—The Genius of France, &c. as above. Reverse, a wreath of oak, containing the words SIX LIVRES; legend,

REPUBLIQUE FRANÇOISE L'AN II.

and round the edge,

LIBERTE, EGALITE,

Liberty, equality.

The 5 FRANC Piece of the Republic—Three figures, representing Hercules and two young women, joining their hands; legend,

UNION ET FORCE,

Union and strength.

Reverse, a wreath of laurel and oak, containing the words 5 FRANCS L'AN 7; legend,

REPUBLIQUE FRANÇOISE;

and round the edge,

GARANTIE NATIONALE,

National guarantee.

The 5 FRANC Piece of 1803—Head of Bonaparte; legend as on the 40 Franc Piece. Reverse, a wreath of laurel, containing the value, 5 FRANCS; legend,

REPUBLIQUE FRANÇOISE,

but, on pieces coined in 1809,

EMPIRE FRANÇOIS.

Round the edge, the words

DIEU PROTEGE LA FRANCE,

as before.

The FRANC of Louis XVIII. bears the same impressions as the 40 Franc Piece of the same period; except the mark of the value.

CORN, in architecture, a kind of die cut diagonal-wise, after the manner of a flight of a stair-case, serving at bottom to support columns in a level, and at the top to correct the inclination of an entablature supporting a vault. Coin is also used for a solid angle composed of two surfaces inclined towards each other, whether that angle be exterior as the coin of a wall, a tree, &c. or interior, as the coin of a chamber or chimney.

COINAGE, as an art, has been carried to the greatest perfection in our own country, and in very modern times. From the establishment of the mint by act of parliament, in the reign of Edward II. to the year 1815, it is surprising how small were the alterations introduced by successive masters: but at this period an entirely new constitution of the mint was projected and accomplished. The history, therefore, of the British Mint and its operations, will embrace everything valuable in this art. See **MINT**.

For **CORNS**, considered as medals, see **NUMISMATICS**.

COINCIDE, *v. n.* } Lat. *coincido*. To fall
COINCIDENCE, *n. s.* } upon the same point; to
COINCIDENT, *adj.* } meet in the same point; to
concur, to agree. The state of several bodies or lines falling upon the same point: tendency of many things to the same end. Occurrence of many things at the same time, without previous arrangement or forethought in their agents.

The very occurrence and *coincidence* of so many evidences that contribute to the proof, carry a great weight.

Christianity teacheth nothing but what is perfectly suitable to, and consistent with, the ruling principles of a virtuous and well-inclined man.

If the equator and ecliptick had *coincided*, it would have rendered the annual revolution of the earth useless.

These circles I viewed through a prism; and, as I went from them, they came nearer and nearer together, and at length became *coincident*.

An universal equilibrium, arising from the *coincidence* of infinite centres, can never be naturally acquired.

The rules of right judgment, and of good ratiocination, often *coincide* with each other.

I venerate the man whose heart is warm, whose hands are pure, whose doctrine and whose life *coincident*, exhibit lucid proof that he is honest in the sacred cause.

COINDICATION, *n. s.* From *con* and *indico*, *l. n.* Many symptoms betokening the same cause.

COJOIN, *v. n.* Lat. *conjungo*. To join with another in the same office.

Thou mayest *cojoin* with something, and thou dost. And that beyond commission.

COIRE, a large and handsome town of Switzerland, capital of the League of God's House, and of the canton of the Grisons, is seated in a valley at the foot of the Alps, abounding in vineyards and game; and said to have been founded by the emperor Constantius. It is divided into two parts: the upper principally

inhabited by Catholics, and the lower by Protestants. The former contains the cathedral built in the eighth century, the bishop's residence, and the town-house, containing the archives of the Canton: the diet of which meets here every three years. The principal support of the inhabitants is the trade carried on along the Rhine to London and Zurich. It was formerly a city of Germany, and was governed by counts, but became a bishopric in the ninth century, and a part of the Grison's Republic in 1526. The government being partly aristocratic, partly democratic. In 1799 it was taken by the French under general Massena, and annexed to the Helvetic Republic. It is thirty-two miles north of Chiavenna, and twenty-two E.S.E. of Glacis.

COISTRIL, *n. s.* Corrupted from *kestrel*. It signifies a mean fellow; a runaway.

He's a coward and a *coistril*, that will not drink to my niece.

COIT, *n. s.* Dut. *kote*: a die. A thing thrown at a certain mark. See **QUOIT**.

The time they wear out at *coit*, kayles, or the like idle exercises.

COITION, *n. s.* Lat. *coitio*. The act by which two bodies come together. Copulation.

By Gilbertus this motion is termed *coition*, not made by any faculty attractive of one, but a syndrome and concurrence of each.

I cannot but admire that philosophers should imagine frogs to fall from the clouds, considering how openly they act their *coition*, produce spawn, tadpoles, and frogs.

He is not made productive of his kind, but by *coition* with a female.

COIN, Job's-tears, a genus of the triandria order, and monocæcia class of plants; natural order fourth, gramina. Male, flowers in remote spikes; cal. a biflorous, beardless glume. Female cal. biflorous glume; cor. a beardless glume; the style by artifice: SEED covered with the calyx, ossified. Of this there are three species, natives of the East and West Indies. The chief is *C. lachryma Jobi*, an annual plant, rising two feet from a fibrous root, with two or three jointed stalks, and single, long, narrow leaves at each joint, resembling those of the reed. At the base of the leaves come out the spikes of flowers standing on short foot-stalks; the seeds greatly resemble those of groundwell; whence the plant has by some writers been called lithospermum. It may be propagated in this country by seeds brought from Portugal, and sown on a hot-bed; after which the young plants should be removed into a warm border, and planted two feet from each other. They require only to be kept free from weeds. In Spain and Portugal the poor grind the seeds of this plant in times of scarcity, and make a coarse kind of bread of them. The seeds are enclosed in small capsules about the bigness of an English pea, and of different colors. These are strung upon silk, and used instead of bracelets by some of the poorer sort in the West Indies, particularly by the negroes.

COKALAHISKIE, a river of North America, which takes its source in the Rocky Mountains, and, after a course of about 300 miles,

enters Clark's River, a branch of the Columbia, in long. 113° W., lat. 47° N. It is deep and rapid, and its average width about sixty yards. In one part of its course it approaches within sixty miles of Dearborn's Creek, a branch of the Missouri.

COKE, *n. s.* Lat. *lignum coctum*. Fuel made by burning pit-coal under earth, and quenching the cinders; as charcoal is made with wood. It is frequently used in drying malt.

COKE, or **COAK**, charred pit-coal, much used for smelting iron ore in malt-houses, and other places where smoke is to be avoided. It is usually prepared by putting screened coal into cylindrical ovens of brick or stone, generally about six feet by seven, and eight feet in height, and there burning it. When it is red-hot the apertures are all closed, and it is left to cool; it is then drawn out with long iron rakes, and the mass is found to have assumed an arrangement not much unlike starch. An improvement has been adopted by Lord Dundonald, by means of which he receives, in a separate chamber, the coal tar. Baron Von Haak, at Newcastle, distilled the coal in cast-iron chambers, but he withdrew the soot for lamp black before the rise of the gray ashes; but the coak thus formed is not so well fitted for the iron smelting.

COKE (Thomas), LL. D. a respectable divine among the Wesleyan methodists, was born September 9th, 1747, at Brecon, in South Wales, where his father was a surgeon and a magistrate. Receiving a classical education, in the public school of that place, he went, as a gentleman commoner, to Jesus College, Oxford. In 1770 he took the degree of master of arts, and in 1775 that of doctor in civil law; became, in the interim, a member of the corporation, and mayor of his native place. Soon after this he became acquainted with Mr. Wesley, and, entering into orders, obtained the curacy of South Petherton, in Somersetshire. He was soon dismissed from his curacy, when he preached at the church-door, which occasioned a riot; and on this he timely left Petherton to become an assistant of Mr. Wesley. In 1784 the latter is said to have consecrated him as a bishop for the purpose of superintending the methodistical societies in America. The doctor now, therefore, made several voyages to the United States and the West Indies, establishing meeting-houses, organising congregations, and ordaining ministers. He also visited Ireland, where he held and presided over several conferences. About the commencement of the French revolution, he attempted a mission in that country, but failed in his object. He next turned his attention to the Wesleyan cause in Wales, which he lived to see very flourishing. He now formed an establishment at Gibraltar; and on the 21st of February, 1814, sailed with some preachers for Ceylon; but on the 3d of May was found dead in the cabin of the vessel, having fallen on the floor in an apoplectic fit. He published a Commentary on the Bible; a History of the West Indies; and some Sermons and Tracts.

COKE (Sir Edward), lord chief justice of the king's bench in the reign of James I. was descended from an ancient family in Norfolk, and

born at Milham in 1549. When a student, in the Inner Temple, he distinguished himself by stating the case of a cock belonging to the Temple so exactly, that all the house admired him, and the whole bench took notice of him. After his marriage with a lady of good fortune, preferments flowed upon him. The cities of Norwich and Coventry chose him for their recorder; the county of Norfolk for one of their knights in parliament; and the house of commons for their speaker, in the thirty-fifth year of queen Elizabeth. The queen appointed him solicitor-general in 1592, and attorney-general in 1593. In 1603 he was knighted by king James I.; and the same year, upon the trial of Sir Walter Raleigh, at Winchester, he treated that gentleman with a scurrility of language hardly to be paralleled. On June 27th he was appointed lord chief justice of the common pleas, and in 1613 lord chief justice of the king's bench, and one of the privy council. In 1615 he was very vigorous in the discovery and prosecution of the persons employed in poisoning Sir Thomas Overbury in the Tower in 1612. His contest not long after with the lord chancellor Egerton, with some other cases, hastened the ruin of his interest at court: so that he was sequestered from the council table, and the office of lord chief justice. In 1621 he vigorously maintained, in the house of commons, that no proclamation is of any force against the parliament. The same year, being looked upon as one of the great incendiaries in the house of commons, he was removed from the council of state with disgrace; the king saying that 'he was the fittest instrument for a tyrant that ever was in England;' he was also committed to the Tower, and his papers were seized. Upon the calling of a new parliament, in 1625, the court party, to prevent his being elected a member, got him appointed sheriff of Buckinghamshire. To avoid the office he drew up exceptions against the oath of a sheriff, but was obliged to undertake the office. In 1628 he spoke vigorously upon grievances; and made a speech, in which he affirmed, that 'the duke of Buckingham was the cause of all our miseries.' While he lay upon his death-bed his papers and last will were seized by an order of council. He died in 1634. He published many works; the most remarkable are his Institutes of the Laws of England; the first part of which is a translation and comment of Sir Thomas Littleton, one of the chief justices of the common pleas in the reign of Edward IV.

COKEsbury COLLEGE, a college in the State of Maryland, in Abington, Harford county, founded by the Methodists in 1783, and takes its name from Thomas Coke, and Francis Asbury, the American bishops of the Methodist Episcopal church. The edifice is of brick, handsomely built, on a healthy spot, enjoying a fine air, and a very extensive prospect. The college was erected, and is wholly supported by subscriptions and voluntary donations. The students, who are to consist of the sons of travelling preachers, annual subscribers, members of the society, and orphans, are instructed in English, Latin, Greek, logic, rhetoric, history, geography, natural philosophy, and astronomy.

and they are taught the Hebrew, French, and German languages.

COL, one of the western islands of Scotland, about thirteen miles long and three broad; containing above 800 inhabitants. It abounds in corn, pasture, salmon, eels and cod. It lies on the coast of Argyllshire, nine miles from Ardnarmuchan, and eleven north-west of the Isle of Mull. Lon. 7° 15' W., lat. 57° 0' N.

COL D'AGNELLO, a passage from France, into Italy from Guillaire to Chateau Dauphin.

COL D'AREZ, a passage of the Pyrenees from Prats de Molo in France, to Campredon in Spain.

COL D'ARGENTIERE, a passage from France into Italy between Saluce and Nice.

COL DE LIMON, a passage over the Alps, from Sospello to Coni.

COL DE PARACOLS, a passage of the Pyrenees, from Ceret in France, to Ampardan in Spain.

COL DE PERTUIS, a passage of the Pyrenees, between Boulou and Junquera.

COL DE TENDA, a well-known passage of the Alps, between Piedmont and Nice, over the mountains of Tenda, and 500 feet above the level of the sea.

COLAN, a town of South American Indians, in Peru, within the jurisdiction of Piura. The inhabitants are very industrious; they raise much grain, and feed great numbers of cattle; and they make large rafts of wood, with which they make voyages to Panama. Their cargoes consist of wine, oil, sugar, soap, dressed goat skins, and Quito cloth. Their grain and cattle are disposed of at Payta and the adjacent towns. Colan is nine miles north from Payta.

COLANDER, *n. s.* Lat. *colo*; to strain. A sieve either of hair, twigs, or metal, through which a mixture to be separated is poured, and which retains the thicker parts; a strainer.

Take a thick woven oster *colander*,
Through which the pressed wines are strained clear.
May.

All the viscera of the body are but as so many *colanders* to separate several juices from the blood.

Ray on the Creation.

The brains from nose and mouth, and either ear,
Came issuing forth, as through a *colander*
The curdled milk. *Dryden.*

COLAPIS, or **COLOPS**, in ancient geography, a river of Liburnia, which, after a winding north-east course, falls into the Savus at the Insula Segestica. It is now called Culpe.

COLAPOOR, or **CALAPUN**, a small independent Mahratta state, on the sea coast of Bejapoor, Hindostan, sometimes called Bonsolo in the maps. It is the only one entirely independent of the British, and bounded to the south by the Portuguese territory of Goa; to the eastward, and northward by the Peishwa's dominions, and to the west by the sea. Its chief towns are Colapoor, Vingorlat, and Raree, the two latter being considerable ports. The rajah gained a great accession of country by conquest, during the confusion in the Mahratta Peshwa's dominions, after the death of Sewai Madhoorow, particularly from the Putwurdun family.

COLAR, a district in the eastern extremity of

the Mysore territories, between the thirteenth and fourteenth degrees of north latitude, consisting, for the greater part, of rocky mountains. Those towards the capital are very extensive. The road leading to it being flanked by high hills. The remainder of the district is largely covered with copse wood. But the mango, tamarind, and robinia matis, flourish in particular spots, and salt is made in the lower parts. The natives also plant aloes in the hedges, and use the leaves for cordage. Gold dust is said to be found in considerable quantity.

This district is very fruitful in rice, being well watered; but the enmity of its different tribes to each other has been often exemplified. Aurungzebe overran this country, and burnt down Vingorla in 1684, a few years after it had been taken by the celebrated Serajee from the king of Bejapoor. More recently, when the father of the rajah was taken in war by Appa Saheb, one of the Putwurdun family, although he was a Brahmin, and much wounded, the barbarian captor ordered him to be cut in pieces before his face.

In 1804, when a British squadron had blockaded the ports of the rajah, in consequence of the numerous piracies committed by his subjects, that prince also gave shelter to two of his relations, whom lord Wellington had found at the head of banditti. The British general, therefore, wrote to him, stating that he was perfectly aware of the family connexion between the rajah and those brothers, and that it was not the custom of the British government, nor his own wish, to perpetuate enmities, or deprive those of an asylum who were inclined to live in peace; for which reason he did not call on the rajah to give up the brothers, but notified to him, that, as he had given them an asylum, the British government would consider him responsible for their conduct; and if they again assembled troops, which could only be intended to disturb the peace of other powers, he (the rajah) would be called upon to answer for the injuries they might do. The intimation had the desired effect, and the neighbourhood is said to have enjoyed an extraordinary tranquillity in consequence of this interference.

COLAR, the capital of the above district, has extensive mud fortifications; but in the centre is a cavalier of stone, and it is defended by a deep ditch. This place was taken by the English in the year 1768, and shortly after retaken by Hyder Ali. His father Futteh Mahommed resided here, and began a mosque and mausoleum, which Hyder finished. The establishment is still supported at the expense of the British.

COLARBASIANS, or **COLORBASIANS**, a sect of Christians in the second century; so called from their leader Colarbasus, a disciple of Valentinus; who, with Marcus, another disciple of the same master, maintained the whole plentitude and perfection of truth and religion to be contained in the Greek alphabet; and that it was upon this account that Jesus Christ was called the alpha and omega. This sect was a branch of the Valentinians.

COLATION, *n. s.* From *colo*, Lat. The art of filtering or straining.

COLATURE, *n. s.* From *colo*, Lat. The act of straining; filtration; the matter strained.

COLBERG, a strong handsome sea-port town of Prussia, in Farther Pomerania. It is remarkable for its salt-works, and is seated at the mouth of the river Persante, on the Baltic sea. The chief edifices are the town-house and the cathedral, a large and beautiful structure. The aqueduct also which supplies the town with water is a well contrived and strong building. Colberg is a fortress of some importance; it was three times besieged by the Russians during the seven years' war, twice without success. It is sixty miles north-east of Stetin, and thirty of Canin.

COLBERT (John Baptist), marquis of Segnelai, one of the greatest statesmen of France, was born at Paris in 1619; and descended from a family in Rheims, no way considerable for its splendor or antiquity. His grandfather and father were merchants; and young Colbert was bred up to the same profession; but afterwards became a clerk to a notary. In 1648 his relation, John Baptist Colbert, lord of S. Pouange, preferred him to the service of Michael Le Tellier, secretary of state, whose sister he had married. Le Tellier afterwards recommended him to the service of cardinal Mazarine, and by him he was sent to Rome, to negotiate the reconciliation of cardinal de Rets, and other important business. So high an opinion had Mazarine of Colbert's abilities and faithful services, that, at his death, in 1661, he recommended him to Louis XIV. as the most eligible person to regulate the finances, which at that time stood in much need of reformation; and Louis, in consequence, made Colbert intendant of the finances. This minister established the trade with the East and West Indies, from which France derived innumerable advantages. In 1664 he became superintendent of the buildings; and applied himself so earnestly to the enlarging and adorning of the royal edifices, that they became master-pieces of architecture; as the palace of the Thuilleries, the Louvre, St. Germain, Fontainebleau, and Chombord attest: and he raised Versailles from the ground. It was formerly a dog-kennel, where Louis XIII. kept his hunting furniture; he made it a palace fit for the greatest monarch. He established the Academy for Painting and Sculpture, and the Academy of Sciences, as well as the Royal Observatory at Paris. France also owes to him all the advantages she receives by the union of the two seas; a prodigious work, begun in 1666, and finished in 1680. In 1672 he was made prime minister, and died of the stone September 6th, 1683, in his sixty-fifth year, leaving behind him six sons and three daughters. His mien was low and dejected, his air gloomy, and his aspect stern. Colbert was a lover of learning, though he never applied to it himself; and conferred donations and pensions upon scholars in other countries, while he established and protected academies in his own. He invited into France eminent artists of all kinds; thus giving new life to the sciences, and making them flourish exceedingly. Upon the whole, he was a wise, active, public-spirited minister; ever attentive to the interests of his master, the happiness of the people, the pro-

gress of arts and manufactures, and every thing that could advance the credit and interest of his country. He was a pattern for all ministers of state; and every nation may wish to be blessed with a Colbert.

COLBERTINE, *n. s.* A kind of lace worn by women.

Go, hang out an old frisoner gorget, with a yard of yellow *colbertine* again.

Congreve's Way of the World.

Difference rose between
Meehlin, the queen of lace, and *Colbertine*.
Young.

COLCHESTER, a town of England, the capital of the county of Essex, pleasantly extended on the brow of a hill, on the south side of the river Colne. It is said to be the ancient Colonia Cameloduni, and that both town and river derive their names from the word Colonia. It was called by the Saxons Colneceaster. There seems indeed ample proof that it flourished under the Romans, several buildings full of their bricks, and great quantities of coin, having been dug up in the town and its vicinity. A curious tessellated or mosaic pavement, three feet under the surface of the earth, was discovered in a garden in 1763.

Colchester is said to have been the birth-place of Constantine the Great, his mother Helen being daughter of a governor of the district under the Romans; and that, from Helen finding out the cross of Christ at Jerusalem, the arms of the town are a cross regulee between three ducal coronets, two in chief and one in base; the coronet in chief passing through the cross. The walls of the town were in general about nine feet thick; and on the south-east and west sides considerable remains of them appear.

Colchester, at the period of compiling the Domesday Survey, had no less than 276 burgesses. It was besieged during the commotions in the reign of John, by Saher de Quincy, earl of Winchester, at the head of an army of foreigners, but was relieved by the approach of the barons, who were assembled in London, and from whom the earl retreated to Bury St. Edmunds. Saher, however, or some of his party, shortly after obtained possession of and plundered the town, leaving a garrison in the castle; but of this they were not long possessed, for, being soon besieged by king John, they were forced to surrender. In the year 1218 it fell into the hands of the troops of Louis, son to Philip II. of France, who visited England with the professed intention of supporting the demands of the barons; but really, as it would seem from their conduct, to make conquests for themselves. The castle was not long disgraced, however, by the display of the French flag, for the submission of the barons to Henry III. soon enabled that prince to expel the faithless Louis.

During the reign of Edward III. the inhabitants were much harassed by the aggressions of Lionel de Bradenham, who, enraged at being foiled in his endeavours at obtaining the exclusive fishery of the Colne, which had been granted to the burgesses by Richard I. beset the approaches to the town for three months, with a

band of daring villains, and proceeded even to an attempt at destroying it by fire.

This town warmly espoused the cause of Mary at the period of the attempt being made to place the unfortunate lady Jane Grey upon the throne. It was honored in consequence with a visit by Mary, shortly after her establishment on the throne. Here, however, she suffered the torch of bigotry to blaze. Upon the accession of Elizabeth, a different scene presented itself. A colony of Flemings, fugitives from the persecutions of the duke of Alva, were admitted to settle here, and establish the baize manufacture, for which the town was long celebrated.

In 1648, towards the end of the civil war, this town sustained a siege of ten weeks; and, making a very gallant defence, the siege was changed into a blockade, wherein the garrison and inhabitants suffered extremely for want of provisions. They were at last obliged to surrender at discretion, when their two gallant chief officers, Sir Charles Lucas and Sir George Lisle, were shot under the walls in cold blood. Colchester was made the see of a suffragan bishop by a statute of Henry VIII.

The castle commands, from the north of the High street, a magnificent view to the north and east; the outer walls are nearly perfect, they are built of an admixture of silicious and calcareous stones and Roman brick. By Norden the erection of this fortress is ascribed to Edward the elder; but the Saxon chronicle refers it to Eudo Dapifer, sewer or steward to William the Conqueror, and its testimony receives no small confirmation from the circumstance of its general structure being Norman; while the immense quantity of Roman bricks, not single but united into masses, would indicate it to have been erected upon the site of a more ancient Roman fortress.

The plan of the castle is a parallelogram, measuring upon its east and west sides 140 feet, and upon the north and south 102 feet; with projecting square towers to the north-east and north-west angles: at the south side on the west face there is another square tower; and a semicircular tower, having a radius of twenty feet, upon the east face. The thickness of the foundations is thirty feet; that of the lower part of the walls twelve, and of the upper nearly eleven feet. The chief entrance is beneath a strong semicircular arch, with three-quarter columns, situated near the south-west tower, here the capitals are of the Norman order of architecture. A portcullis formerly defended this entrance, within which, upon the right, the guard or janitor was stationed, in a niche: not far hence is a square room, having, at its further end, a flight of stairs leading to the vaults, of which that which is situated immediately at the foot of them measures twenty-six feet in length and twenty-one in breadth; the narrow passage at its extremity is bricked up, to prevent the accidents which might arise from the ruinous condition of the arch of the next vault into which it leads. Upon the right of this first vault, a passage has been broken through the wall into an adjacent one, from which the light is wholly excluded, and whose dimensions are similar: hence, through a

chasm at its extremity, a passage leads to a third vault of the same breadth as the others, but much longer. When first discovered, about 100 years since, these vaults were found full of sand; the original descent to them is still undiscovered.

Beyond the stairs is an entrance into a large area formerly roofed, and divided by a wall running north and south. Within this space, upon its different floors, were the principal apartments of the castle: and also a gallery that runs between the wall which crosses the area, and that which is demolished.

At the extremity of a wall which separates this area from a second, is a door above and below, which led into the apartments which filled the space between the east wall of the castle and gallery. At the south end of this space, in the south-east tower, on the ground floor is a strong arched room, with walls of an astonishing thickness. In the south-west tower is the grand staircase, which is circular, arched above and built of stone; this leads to a modern room, used as a subscription library. An arcade of modern workmanship, which runs along the north wall of the library, leads to the ancient chapel, which is a venerable piece of architecture, the beauty of whose proportions strike the eye, notwithstanding the massiveness of its construction. The roof is strongly arched, and the light is admitted through five windows, of which two have been enlarged, while the rest continue nearly in their original state. This building is forty-seven feet long, nearly forty broad, and proportionably high. Prisoners are confined in the arched vault beneath it.

In the north-east and north-west towers, upon the same floor with the chapel, are various small rooms or recesses, and in the latter is also a staircase, which descends from the upper part of the tower, and terminates at the first floor. At the foot of the stairs, in the north wall of the castle, is a sally-port, now closed up, which opened upon an abutment of the north-west tower. This sally-port, which is nine feet wide, and the great gateway in the south wall, are the only original entrances into the castle. From the principal staircase, in the north-east tower, another flight of steps leads to what was the second floor; the walls of this story, of which but a very small part now remains, were nine feet thick. The dome which covers the staircase, the passage formed upon the west and north wall of the castle, and the small room upon the summit of the north-east tower, are all of modern construction. The great doorway in the north wall, and the small port in the east wall, are likewise modern, and have been formed with great labor, by the enlargement of a narrow window in each place. Several of the windows have also been, with no less labor, enlarged: in their original state but a very scanty portion of light could have found entrance into the interior apartments. The peculiar construction of these windows, so entirely different from any in modern buildings, is worthy of observation. An arched niche, about three feet deep, formed the inner opening of the window; in the back of which niche, another of less di-

mensions, gradually decreasing in breadth, penetrated about seven feet further, at the extremity of which a narrow aperture, only eight inches wide, lined with hewn stone, was made through the remaining thickness of the wall. From the floor of the rooms an ascent was made to the narrow aperture of the window by a flight of small steps. The outside of the building is surrounded on every part with several horizontal bands or fillets of Roman brick, which are disposed in perpendicular and oblique layers.

Colchester castle was granted by the empress Maud to Alberic de Vere, ancestor of the Veres, earls of Oxford; Alberic does not however appear ever to have had possession of it. Stephen Harengod next obtained a grant of it during pleasure. In 1256 it was given by Henry III. to Guido de la Rupe Ford, or Rochford, who was, however, in consequence of disgrace, deprived of this along with his other estates two years afterwards. From this period it has repeatedly changed masters, one of whom, of the name of Wheeley, made an attempt at dilapidating it in the year 1683; the solidity of the building, however, proved its security, as the expense attending the demolition of a very small part was so enormous as to deter its owner from proceeding further.

There are twelve parishes in the town and suburbs of Colchester, of which eight are within and four without the walls; several of the churches are, however, destroyed; but some that remain there are handsome structures. The ruins of St. John's Abbey in particular merit attention: this building was founded by Eudo Dapifer in 1097, and appears to have been a very magnificent structure. It was dedicated to St. John the Baptist, and occupies the site of a wooden church, dedicated to St. John the Evangelist, which was famous for miracles. When completed, about the beginning of 1104, it was consecrated by Maurice, bishop of London: at which time also its endowment was liberally augmented by its original founder Eudo, and other pious persons. This foundation flourished till the period of the dissolution, its privileges being the same with those of the abbey of St. Peter's, Westminster, and its abbot possessing a seat in parliament. At the time of the dissolution its revenues were estimated at £523. 17s. 10d. Beche, the last abbot, was hung for refusing to acknowledge the king's supremacy. The gateway which remains appears more modern than the other parts of the abbey, and is built of hewn stone and flint; the garden walls enclose an area of little less than fourteen acres.

St. Giles's church, of which only the chancel, which is employed for the celebration of divine worship, is preserved from ruin, stands near the north-west corner of St. John's garden, and was the burying place of the Lucas family; here are interred the remains of the gallant Sir Charles Lucas, and his no less gallant, though equally unfortunate fellow sufferer, Sir George Lisle, whose melancholy fate is recorded upon their common tomb.

St. Botolph's priory, which stands at a short distance north-east of St. John's. Its foundation is commonly, though not improbably with-

out sufficient justice, ascribed to a monk of the name of Eyrnulph, or Ernulph, early in the twelfth century: some of the ruins seem, however, to speak a much more remote origin. The revenues were, at the dissolution, £134. 13s. 4d. per annum; but few traces of the monastic buildings can be now discovered. Previously to the siege, the priory church continued perfect; it was then however almost totally destroyed, each of the contending parties accusing the other of the deed. The curious specimens of brick ornaments and interlaced arches, which they present, furnish the admirer of architectural relics with much interesting contemplation. As it stood, originally, the dimensions of this church were, within the walls, 108 feet long, and, including the nave and aisles, forty-four feet broad. Its west front was richly ornamented, and contained the grand entrance, which still remains. The door-way is formed by a fine semicircular retiring arch, with various mouldings, formed with alternate rows of small thin brick, and hewn stone.

On the south-west side of the town was formerly a monastery of Crouched Friars, established at the first arrival of that order in this country, about the year 1244. The fabric underwent many changes, and became in 1407 the seat of the wealthy Guild of St. Helen, along with whose possessions not less than four chantries, founded here, and in the church of St. Nicholas, were incorporated. Its revenues came, soon after the dissolution, into the hands of lord chancellor Sir Thomas Audley; and the building was in 1637 converted into a dwelling-house.

The principal church within the walls is St. James's; the rest are All Saints, St. Nicholas, partly in ruins; the chapel of St. Helen; Trinity church; St. Runwald's, St. Martin's, St. Peter's, and St. Mary's. The moot hall, for holding the court in, and transacting the public business, was founded by Eudo Dapifer, already mentioned: the town gaol adjoins, and is partly situated under this building, and the theatre behind it. There are several charitable institutions here for the instruction as well as relief of the poor; and this town is one of those included in the gift of the late Sir Thomas Whichcote.

The first charter of incorporation was granted to this town by Richard I. in the year 1193, when many valuable privileges, especially the exclusive fishery of the Colne between the north bridge and west bridge, were conferred upon the burgesses. Their charter has received repeated confirmations and extensions, from succeeding monarchs; the last, by which at present the government of the corporation is regulated, having been granted by his late majesty George III. in the year 1763.

The corporation now consists of a mayor, recorder, town-clerk, twelve alderman, eighteen assistants, eighteen common-councilmen, and inferior servants; it returns two members to parliament; the right of election being vested in the corporation and the burgesses who do not receive alms; the number of electors is estimated at 1400. It seems to have sent burgesses to parliament from the reign of Edward I.

Colchester enjoys an excellent market on Wednesday and Saturday, and, besides the manufacture of baize, furnishes employment to many of its inhabitants in the oyster fishery; the best of which are distinguished by the name of *pyerleet*.

The following is said to be the method of managing them. In May the oysters cast their spawn, which the dredgers call spat; this resembles a drop of candle grease, and equals the size of a halfpenny; it cleaves to stones, old oyster shells, &c. at the bottom of the sea, which they call culch. It is conjectured, with some appearance of probability, that a shell begins to form upon the spat in twenty-four hours. In May the dredgers are permitted by the admiralty court to take oysters of every size. When they have taken them they raise the small breed from the culch with a knife, and then throw in the culch again to preserve the ground for the future, unless they are so newly spat that they cannot with safety be raised from the culch: they are in such cases permitted to take the stone or shell, &c. upon which the spat is, one shell having frequently twenty spats. It is felony to carry away the culch after May, and punishable to take any oysters of a size less than an half-crown piece, or of such a size as to admit of a shilling fairly rattling between the shells when closed.

Among modern improvements here are a new theatre in Queen-street, and a new market. To these may be added the erection of the new bridge over the Colne, called East Bridge; the levelling of St. John's Green, and the widening the road by St. Giles's church. There is a fine quay on the river, which has been rendered navigable, and the water flows from five to seven feet at neap, and from nine to ten feet at spring tides. Vessels of 100 tons or more can come up to it; and Colchester is considered a port, though eight or nine miles from the nearest sea. Distant fifty-one miles north-east from London, and eighteen S. S. W. of Ipswich.

COLCHESTER, a post town of Virginia, in Fairfax county, situated on the north-east bank of Occoquan creek, three or four miles from its confluence with the Potowmack; where it is about 100 yards wide, and navigable for boats. It lies sixteen miles south-west of Alexandria, 106 north by east of Richmond, and 172 from Philadelphia.

COLCHESTER, the chief town in Chittenden county, Vermont, on the east bank of lake Champlain, at the mouth of Onion River, and north of Burlington, on Colchester Bay, which spreads north of the town.

COLCHI, in ancient geography, a town of the Hither India, mentioned by Ptolemy and Arrian; supposed to be Cochin, on the coast of Malabar.

COLCHICUM, meadow saffron, a genus of the trizonia order, and hexandria class of plants, natural order ninth, syriaceae; con. sexpartite, with its tube radicated, or having its root in the ground; caps. three, connected and inflated. There are three species, all bulbous-rooted, low, perennials, and peculiar in that their leaves appear at one time, and their flowers at another:

the former rising long and narrow at the root in spring, and decaying in June; the flowers, which are monopetalous, long, tubular, erect, and six-parted, rise naked from the root in autumn, not more than four or five inches high. The root of this plant is poisonous. When young and full of sap, its taste is very acrid; but when old, mealy and faint.

COLCHIS, a country of Asia, at the south of Asiatic Sarmatia, east of the Euxine Sea, north of Armenia, and west of Iberia. It is famous for the expedition of the Argonauts, and as the birth-place of Medea. It was fruitful in poisonous herbs, and produced excellent flax. The inhabitants were originally Egyptians, who settled there when Sesostris king of Egypt extended his conquests in the north. It is now called Mingrelia, and belongs to the Turks.

COLCOTHAR, *n. s.* A term in chemistry. See VITRIOL.

Colcothar is the dry substance which remains after distillation, but commonly the caput mortuum of vitriol. *Quincy.*

Colcothar, or vitriol burnt, though upon a redness, containing the fixed salt, will make good ink. *Brown.*

COLD, *adj. & n. s.* } Sax. geliel. Wanting, or without heat; cold;

COLDLY, *adv.* } frigid; applied intellectually, morally, and physically. The last application embraces whatever is chilling to the sense;

the second to the obscure of all passionate excitement; the des titution of kindness and affection. In a good sense to chastity, and the frigid virtues: the principles that subdue the appetites and desires. The first describes an indifferent, inactive, unconcerned state of the mind; a mind without imagination; addicted to philosophy rather than poetry: clear, but gelid.

He knew the cause of every malady,
Were it of cold, or hot, or moist, or drie,
And wher engendered, and of what humour:
He was a veray parfitte practisous.

Chaucer. Canterbury Tales.
Upon the morve when that it was day,
To Bretagne token they the righte way,—
Aurelie, and this magicien him beside,—
And ben descended ther they wold abide:
And this was as the bookes me remember,
The colde frosty sason of December. *Id.*

So layne he tooke his lady in distresse,
And layd her underneath a bush to sleepe,
Covered with cold, and wrapt in wretchednesse;
Whiles he himselfe all night did nought but weepe,
And wayre watch about her for her safeguard keepe.

There sprung up one kind of men, with whose zeal and forwardness the rest, being compared, were thought to be marvellous cold and dull. *Spenser.*

Infinite shall be made cold in religion, by your example, that never were hurt by reading books. *Hooker's Preface.*

Heat and cold are nature's two hands, whereby she chiefly worketh: and heat we have in readiness, in respect of the fire; but, for cold, we must stay till it cometh, or seek it in deep caves, or high mountains: and, when all is done, we cannot obtain it in any great degree. *Ascham.*

Heat and cold are nature's two hands, whereby she chiefly worketh: and heat we have in readiness, in respect of the fire; but, for cold, we must stay till it cometh, or seek it in deep caves, or high mountains: and, when all is done, we cannot obtain it in any great degree. *Bacon's Natural History.*

Cold plants have a quicker perception of the heat of the sun than the hot herbs; as a cold hand will sooner find a little warmth than an hot. *Id.*

Smell this business with a sense as cold
As is a dead man's nose.

Shakspeare. Winter's Tale.

You may

Convey your pleasures in a spacious plenty,
And yet seem cold, the time you may so hoodwink;
We've willing dames enough.

Id. Macbeth.

She made it good

At the edge corner, in the coldest fault.

Id.

O noble English, that could entertain,
With half their forces, the full power of France;
And let another half stand laughing by,
All out of work, and cold for action.

Id. Henry V.

New dated letters these,

Their cold intent, tenor, and substance thus;
Here doth he wish his person, and his power,
The which he could not levy.

Id. Henry IV.

We should not, when the blood was cold, have
threatened our prisoners with the sword.

Id. Cymbeline.

My master's suit will be but cold,

Since she respects my mistress's love.

Id. Two Gentlemen of Verona.

What a deal of cold business doth a man mispend
the better part of life in? In scattering compliments,
tendering visits, following feasts and plays.

Ben Jonson.

The aggregated soil

Death, with his mace petrifick, cold, and dry,
As with a trident smote.

Milton.

Bids us seek

Some better shroud, some better warmth, to cherish
Our limbs benumbed, ere this diurnal star
Leave cold the night, how we his gathered beams
Reflected, may with matter sere foment.

Id.

Such was the discord, which did first disperse
Form, order, beauty, through the universe;
While dryness moisture, coldness heat resists,
All that we have, and that we are, subsists.

Denham.

Come little infant love me now,

While thy unsuspected years

Clear thy aged father's brow

From cold, jealousy, and fears.

Marvell.

Love wisely had of long foreseen

That he must once grow old;

And therefore stored a magazine

To save him from the cold.

Id.

When she saw her lord prepared to part,
A deadly cold ran shivering to her heart.

Dryden's Fables.

To see a world in flames, and an host of angels in
the clouds, one must be much of a stoic to be a cold
and unconcerned spectator.

Burnet's Preface to the Theory of the Earth.

Unhappy youth! how will thy coldness raise
Tempests and storms in his afflicted bosom.

Addison's Cato.

Let every tongue its various censures chuse,
Absolve with coldness, or with spite accuse.

Prior.

Swift seemed to wonder what he meant,

Nor would believe my lord had sent;

So never offered once to stir,

But coldly said, Your servant, Sir.

Swift.

The silver stream her virgin coldness keeps,
For ever murmurs, and for ever weeps.

Pope's Windsor Forest.

The diet in the state of manhood ought to be solid;
and their chief drink water cold, because in such a state
it has its own natural spirit.

Arbuthnot on Aliments.

Cold the soft hand that soothed woe's weary head!
And quenched the eye, the plying tear that shed!
And mute the voice whose pleasing accents stole
Infusing balm into the rankled soul.

Beattie.

Restore those tranquil days that saw me still
Well pleased with all, but most with human kind,
When Fancy roamed through nature's works at will.
Unchecked by cold distrust, and uninformed of ill.

Coldness or anger, even disdain or hate

Are masks it often wears, and still too late.

Byron.

COLD, *n. s.* A disease induced by exposure
to the atmosphere in a too gelid state; or in a
state unsuited to the body at the time.

What disease hast thou?

A whoreson cold, Sir; a cough.

Shakspeare. Henry IV.

COLD, in farriery. See FARRIERY, Index.

COLD, in medicine. See MEDICINE, Index.

COLD, in natural philosophy, signifies, in a relative sense, the sensation which accompanies a transition of the fine vessels of the human body from an expanded to a more contracted state. In an absolute sense, it signifies the cause of this transition; or, in general, the cause of the contraction of every substance, whether solid or fluid, in nature. Great discussion has been excited in modern times as to the nature of cold, whether it be a positive or a negative quality.

Cold tends to make bodies electric which are not so naturally, and to increase the electric properties of those which are. All bodies do not transmit cold equally well; but the best conductors of electricity, viz. metals, are likewise the best conductors of cold. When the cold has been carried to such an extremity as to render any body electric, it then ceases to conduct the cold as well as formerly. This is exemplified in the practice of the Laplanders and Siberians, where the cold in winter is extremely severe. In order to exclude it from their habitations the more effectually, they cut pieces of ice, which in the winter time must always be electric in these countries, and put them into their windows; which they find to be much more effectual in keeping out the cold than any other substance.

Cold, as well as heat, may be produced artificially, though we have no method of making cold increase itself as heat will do. The reason of this is obvious; for, if it consist in a partial cessation of motion in the elementary fluid, it is plain, that though we may partly put an end to this motion in a very small part of it, yet that of the surrounding atmosphere, extending for an immense way farther than we can extend our influence, will quickly counteract our operations, and reduce the bodies to the same temperature they were of before. Though there are therefore some liquids which by mixture will produce considerable degrees of cold, yet, by being left to the action of the surrounding warm atmosphere, the heat is quickly communicated from it to them, and the effect of the mixture ceases. The case is very different with heat; for this fluid, of itself naturally very much inclined to motion, no sooner finds an opportunity of exerting its action, than vast quantities of what was formerly at rest rush from all quarters to the place where the action has commenced, and continue

it until the equilibrium is restored. The power of producing cold belongs particularly to bodies of the saline class. In the Philosophical Transactions, No. 274, Mr. Geoffroy gives an account of some remarkable experiments with regard to the production of cold. Four ounces of sal ammoniac, dissolved in a pint of water, made his thermometer descend two inches and three-quarters in less than fifteen minutes. An ounce of the same salt put into four or five ounces of distilled water, made the thermometer descend two inches and a quarter. Half an ounce of sal ammoniac, mixed with three ounces of spirit of nitre, made the thermometer descend two inches and five lines; but on using spirit of vitriol, instead of nitre, it sunk two inches and six lines. In this last experiment it was remarked, that the vapors raised from the mixture had a considerable degree of heat, though the liquid itself was so extremely cold. Four ounces of saltpetre mixed with a pint of water, sunk the thermometer one inch three lines; but a little quantity of sea-salt sunk it only two lines. Acids always produced heat, even common salt with its own spirit. Volatile alkaline salts produced cold in proportion to their purity, but fixed alkalis heat. The greatest degree of cold produced by the mixture of salts and aqueous fluids was that shown by M. Homberg: who gives the following receipt for making the experiment: 'Take a pound of corrosive sublimate, and as much sal ammoniac; powder them separately, and mix the powders very exactly; put the mixture into a phial, pouring upon it a pint and a half of distilled vinegar, shaking all well together.' This composition grows so cold, that a man can scarce hold it in his hands in summer; and it happened, as M. Homberg was making the experiment, that the subject froze. The same thing once happened to M. Geoffroy in making an experiment with sal ammoniac and water, but it never was in his power to make it succeed a second time. If, instead of fluid water, we take it in its congealed state of ice, or rather snow, degrees of cold will be produced vastly superior to any yet mentioned. A mixture of snow and common salt sinks Fahrenheit's thermometer to 0; potashes and powdered ice sink it 8° farther; two affusions of spirit of salt on pounded ice sunk it 14½° below 0; but by repeated affusions of spirit of nitre Mr. Fahrenheit sunk it 40° below 0. This is the ultimate degree of cold which the mercurial thermometer will measure: because the mercury itself begins then to congeal: and therefore we must afterwards have recourse to spirit of wine, naphtha, or some other fluid which will not congeal. The greatest degree of cold hitherto producible by artificial means has been 80° below 0; which was done at Hudson's Bay by means of snow and vitriolic acid, the thermometer standing naturally at 20° below 0. Greater degrees of cold than this have indeed been supposed. Mr. Martin, in his Treatise on Heat, relates that at Kizenga in Siberia, the mercurial thermometer sunk to 118° below 0; and professor Brown at Petersburg, when he made the first experiment of congealing quicksilver, fixed the point of congelation at 350° below 0; but Dr. Black, as soon as the experiment was made

known in this country, observed, that in all probability the point of congelation was far above this. His reasons for supposing this were that the mercury descended regularly only to a certain point, after which it would descend suddenly and by starts 100° at a time. This, he conjectured, might proceed from the irregular contraction of the metal after it was congealed; and he observed that there was one thermometer employed in the experiment which was not frozen, and which did not descend so low by a great many degrees. Experience has since verified his conjecture; and it is now generally known, that 40° below 0 is the freezing point of quicksilver. Since the discovery of the possibility of producing cold by artificial means, various experiments have been made on the efficacy of saline substances in this way; all of which, when properly applied, are found to have a considerable degree of power. Dr. Boerhaave found that both sal ammoniac and nitre, when well dried in a crucible and reduced to fine powder, will produce a greater degree of cold than if they had not been treated in this manner. His experiments were repeated by Mr. Walker, apothecary to the Radcliffe Infirmary in Oxford, with the same result: but he found, that his thermometer sunk 32° by means of a solution of sal ammoniac; when Boerhaave's, with the same, fell only 28°. Nitre sunk it 10°. On mixing the two salts together, he found that the power of producing cold was considerably increased. By equal parts of these salts, he cooled some water to 22°, the thermometer standing at 47° in the open air. Adding to this some powder of the same kind, and immersing two small phials in the mixture, one containing boiled and the other unboiled water, he soon found them both frozen, the unboiled water freezing first. Having observed that Glauber's salt, when it retains the water of crystallisation, produces cold during its solution, he tried its power when mixed with the other salts, and thus sunk the thermometer from 65° to 19°; and thus he was able to freeze water when the thermometer stood as high as 70°. And lastly, by first cooling the salts in water in one mixture, and then making another of the cooled thermometers, he was able to sink the thermometer 64°. Thus he froze a mixture of spirit of wine and water in the proportion of seven of the latter to one of the former; and by adding a quantity of cooled materials to the mixture in which this was frozen, the thermometer sunk to -4, or 63°. Spirit of nitre diluted with water reduced the thermometer to -3; and, by the addition of sal ammoniac, to 15, but the cold was not augmented by the addition of sal ammoniac or nitre.

The most remarkable experiment was with spirit of nitre poured on Glauber's salt, the effect of which was found to be similar to that of the same spirit poured on ice or snow; and the addition of sal ammoniac rendered the cold still more intense. The proportion of these ingredients, recommended by Mr. Walker, are concentrated nitrous acid two parts by weight, water one part; of this mixture cooled to the temperature of the atmosphere eighteen ounces, of Glauber's salt a pound and a half avoirdupois, and of sal ammoniac twelve ounces. On adding the

Glauber's salt to the nitrous acid, the thermometer fell from 50° to -1° , or fifty-two degrees; and, on the addition of the sal ammoniac, to -9° . Thus Mr. Walker was able to freeze quicksilver without either ice or snow, when the thermometer stood at 45° . For the experiment four pans were procured of different sizes, so that one might be put within the other. The largest of these pans was placed in a vessel still larger, in which the materials for the second frigorific mixture were thinly spread in order to be cooled; the second pan, containing the liquor, viz. the vitriolic acid properly diluted, was placed in the largest pan; the third pan, containing the salts for the third mixture, was immersed in the second pan likewise, and floated round the third pan; and the liquor for the third mixture was put into wide-mouthed phials, which were immersed in the second pan likewise, and floated round the third pan; the fourth pan, which was the smallest of all, containing its cooling materials, was placed in the midst of the salts of the third pan. The materials for the first and second mixtures consisted of diluted vitriolic acid and Glauber's salt; the third and fourth of diluted nitrous acid, Glauber's salt, and sal ammoniac, in the proportions above mentioned. The pans being adjusted, the materials of the first and largest pan were mixed: this reduced the thermometer to 10° , and cooled the liquor in the second pan to 20° ; and the salts for the second mixture which were placed underneath in the large vessel nearly as much. The second mixture was then made with the materials thus cooled, and the thermometer was reduced to 3° . The ingredients of the second mixture by immersion in this, were cooled to 10° , and, when mixed, reduced the thermometer to -15° . The materials for the fourth mixture were cooled by immersion in this third mixture to about -12° . On mixture they sunk the mercury very rapidly, and seemingly below -40° , though the froth occasioned by the ebullition of the materials prevented any accurate observation. The reason why this last mixture reduced the thermometer more than the third, though both were of the same materials, and the latter of a lower temperature, was supposed to have been, partly, because the fourth pan had not another immersed in it, to give it heat, and partly because the materials were reduced to a finer powder. The experiments were repeated with many variations; but only one mixture appeared to Dr. Beddoes, by whom the account was communicated to the Royal Society, to be applicable to any useful purpose. This is oil of vitriol diluted with about an equal quantity of water; which, by dissolving Glauber's salt, produces about 46° of cold, and by the addition of sal ammoniac becomes more intense by a few degrees. At one time, when Mr. Walker was trying a mixture of two parts of oil of vitriol and one of water, he perceived, that at the temperature of 35° the mixture coagulated as if frozen, and the thermometer became stationary; but on adding more Glauber's salt, it fell again in a short time: but less cold was produced than when this circumstance did not occur, and when the acid was weaker. The same appearance of coagulation took place with other proportions of acid and water, and

with other temperatures. The effect of Glauber's salt in producing cold took place only when it was possessed of its water of crystallisation; and thus the mineral alkali also augmented the cold of some of the mixtures; but, when the water of crystallisation was dissipated, neither of them had any effect of this kind. 'This circumstance,' says Dr. Beddoes, 'leads us to some measure of the theory of the phenomenon. Water undoubtedly exists in a solid state in crystals; it must, therefore, in other cases absorb a determinate quantity of fire before it can return to its liquid state. On this depends the difference between Glauber's salt and mineral alkali, in its different states of crystallisation and efflorescence. The same circumstance, too, enables us to understand the great effect of Glauber's salt; which, as far as I understand, has the greatest quantity of water of crystallisation.' On this the reviewers remark, that 'if in summer the water brought from a deep well is at 52° , in this cheap and easy way it might be reduced to 12° ; and wine placed in it would be chilled.' These excessive degrees of cold occur naturally in many parts of the globe in the winter. It is true, we are very much unacquainted with them in this country: yet in the winter of 1780, Mr. Wilson of Glasgow observed, that a thermometer laid on the snow sunk to 25° below 0; but this was only for a short time; and in general our atmosphere does not admit of very great degrees of cold for any length of time. Mr. Derham however, in 1708, observed in England, that the mercury stood within one-tenth of an inch of its station when plunged into a mixture of snow and salt. In 1732 the thermometer at Petersburg stood at 28° below 0; and in 1737, when the French academicians wintered at the north polar circle, or near it, the thermometer sunk to 33° below 0; and, in the Asiatic and American continents, still greater degrees of cold are very common.

By extreme degrees of cold, trees are burst, rocks rent, and rivers and lakes frozen several feet deep: metallic substances blister the skin like red hot iron: the air, when drawn in by respiration, hurts the lungs, and excites a cough; even the effects of fire in a great measure seem to cease; and metals, though kept for a considerable time before a strong fire, will still freeze water when thrown upon them. When the French mathematicians wintered at Tornea in Lapland, the external air, when suddenly admitted into their rooms, converted the moisture of the air into whirls of snow; their breasts seemed to be rent when they breathed it; the contact of it was intolerable to their bodies; and the spirit of wine, which had not been highly rectified, burst some of their thermometers by the congelation of the aqueous part. Extreme cold very often proves fatal to animals, in countries where the winters are very severe. Thus 7000 Swedes perished, at once, in attempting to pass the mountains which divide Norway from Sweden. It is not necessary, indeed, that the cold, in order to prove fatal to human life, should be so very intense as has been just mentioned. There is only requisite a degree somewhat below 32° of Fahrenheit, accompanied with snow or hail, from which shelter cannot be obtained. The snow

which falls upon the clothes, or the uncovered parts of the body, then melts, and by a continual evaporation carries off the animal heat to such a degree, that a sufficient quantity is not left for the support of life. In such cases, the person first feels himself extremely chill and uneasy; then begins to grow listless, unwilling to walk or use exercise to keep himself warm; and at last becomes drowsy, sits down to refresh himself with sleep, and wakes no more. An instance of this was seen not many years ago at Terra del Fuego, where Dr. Solander, with some others, having taken an excursion up the country, the cold was so intense, that one of their number died. The Doctor himself, though he had warned his companions of the danger of sleeping in that situation, could not be prevented from making that dangerous experiment himself; and though he was awaked with all possible expedition, his body had so much shrunk in bulk, that his shoes fell off his feet, and it was with the utmost difficulty that he was recovered. In those parts of the world where vast masses of ice are produced, the accumulation of it, by absorbing the heat of the atmosphere, occasions an absolute sterility in the adjacent countries, as is particularly the case with the island of Iceland, where the vast collections of ice floating out from the Northern Ocean, and stopped on that coast, are sometimes several years in thawing. Indeed, where great quantities of ice are collected, it would seem to have a power like fire, of both augmenting its own quality and of communicating it to adjacent bodies.

The conversion of all temperatures, however low, of any liquid or solid whatever, into a vapor, is uniformly accompanied with the abstraction of heat from surrounding bodies, or, in popular language, the production of cold; and the degree of refrigeration will be proportional to the capacity of the vapor for heat, and the rapidity of its formation. The application of this principle to the uses of life, was first suggested by Drs. Cullen and Black, but it has been greatly improved and extended by Mr. Leslie. Dr. Cullen seems to have been the first who applied the vacuum of an air-pump to quicken the evaporation of liquids, with a view to the abstraction of heat, or the production of artificial cold and congelation. In the year 1755 he plunged a full phial of ether into a tumbler of water, and on placing it under the receiver, and exhausting the air, the ether boiled, and the surrounding water froze. Mr. Edward Nairne, a London optician, published in 1777 in the Transactions of the Royal Society, 'an account of some experiments made with an air-pump.' After stating, that at a certain point of rarefaction the moisture about the pump furnished an atmosphere of vapor, which effected his comparative results with the mercurial gauge and pear gauge, he says, 'I now put some sulphuric acid into the receiver, as a means of trying to make the remaining contents of the receiver, when exhausted as much as possible, to consist of permanent air only, unadulterated with vapor.' He was thus enabled by this artificial dryness to exhibit certain electrical phenomena to great advantage. The next step which Mr. Nairne took, was to produce artificial cold by the air-pump. 'Having lately received

from my friend Dr. Lind,' says he, 'some ether prepared by' the ingenious Mr. Woolfe, I was very desirous to try whether I could produce any considerable degree of cold by the evaporation of ether under a receiver whilst exhausting.' Accordingly he succeeded in sinking a thermometer, whose bulb was from time to time dipped into the ether in vacuo, 103° below 56° , the temperature of the apartment. Mr. Nairne made no attempt to condense the vapor in vacuo by chemical means, and thus to favor its renewed formation from the liquid surface; which we consider to be the essence of professor Leslie's capital improvement on Cullen's plan of artificial refrigeration. After Nairne's removing the vapor of water by sulphuric acid, to produce artificial dryness, there was indeed but a slight step to the production of artificial cold, by the very same arrangement; but still this step does not appear to have been attempted by any person from the year 1777 to 1810, when professor Leslie was naturally led to make it, by the train of his researches on evaporation and hygrometry.

Having in the month of June introduced a surface of sulphuric acid under the receiver of an air-pump, and also a watch glass filled with water, he found that after a few strokes of the pump, the water was converted into a solid cake of ice, which being left in the rarefied medium, continued to evaporate, and after the interval of about an hour totally disappeared. When the air has been rarefied 250 times, the utmost that under such circumstances can perhaps be effected, is that the surface of evaporation is cooled down 120° Fahrenheit in winter, and would probably, from more copious evaporation and condensation, sink nearly 200° in summer. If the air be rarefied only fifty times, a depression of 80° , or even 100° will be produced.

We are thus enabled by this elegant combination, to freeze a mass of water in the hottest weather, and to keep it frozen, till it gradually waste away, by a continued but invisible process of evaporation. The only thing required is, that the surface of the acid should approach tolerably near that of the water, and should have a greater extent; for otherwise the moisture would exhale more copiously than it could be transferred and absorbed, and consequently the dryness of the rarefied medium would become reduced, and its evaporating energy essentially impaired. The acid should be poured to the depth of perhaps half an inch, in a broad flat dish, which is covered by a receiver of a form nearly hemispherical; the water exposed to congelation may be contained in a shallow cup, about half the width of the dish, and having its rim supported by a narrow porcelain ring, upheld above the surface of the acid by three slender feet. It is of consequence that the water should be insulated as much as possible, or should present only a humid surface to the contact of the surrounding medium; for the dry sides of the cup might receive, by radiation from the external air, such accessions of heat as greatly to diminish, if not to counteract the refrigerating effects of evaporation. This inconvenience is in a great measure obviated, by investing the cup with an outer case, at the interval of about half an inch. If both the cup and

its case consist of glass, the process of congelation is viewed most completely; yet when they are formed of a bright metal, the effect appears, on the whole, more striking. But the preferable mode, and that which prevents any waste of the powers of refrigeration, is to expose the water in a saucer of porous earthen-ware. At the instant of congelation, a beautiful net-work of icy spicula pervades the liquid mass.

The disposition of the water to fill the receiver with vapor, will seldom permit even a good air-pump to produce greater rarefaction than that indicated by three-tenths of an inch of mercury, beneath the barometrical height, at the time. But every practical object may be obtained by more moderate rarefactions, and a considerable surface of acid. The process goes on more slowly, but the ice is very solid, especially if the water have been previously purged of its air by distillation, or boiling for a considerable time. If we use a receiver, with a sliding wire passing down from its top through a collar of leathers, and attach to it a disc of glass; or on applying this to the surface of the water cup, we may instantly suspend the process of congelation; and raising the disc as suddenly, permit the advancement of the process.

'In exhibiting the different modifications of this system of congelation to my pupils,' says Dr. Ure, 'I have been accustomed for many years to recommend the employment of a series of cast-iron plates, attachable by screws and stop-cocks to the air-pump. Each iron disc has a receiver adapted to it. Thus we may, with one air-pump, successively put any number of freezing processes in action. A cast-iron drum of considerable dimensions being filled with steam, by heating a small quantity of water in it, will sufficiently expel the air for producing the requisite vacuum. When it is cooled by affusion of water, one of the above transferrer plates being attached to the stop-cock on its upper surface would easily enable us, without any air-pump, to effect congelation by means of sulphuric acid, in the attenuated atmosphere. Suppose the capacity of the receiver to be one-sixtieth of the iron cylinder; an aeriform rarefaction to this degree would be effected in a moment by a turn of the stop-cock; and, on its being returned, the moisture below would be cut off, and the acid would speedily condense the small quantity of vapor which had ascended. This cheap and powerful plan was publicly recommended by me upwards of ten years ago, when I had a glass model of it made for class illustration.'

The combined powers of rarefaction, vaporisation, and absorption, are capable of effecting the congelation of quicksilver. If this metal, contained in a hollow pear-shaped piece of ice, be suspended by cross threads near a broad surface of sulphuric acid, under a receiver; on urging the rarefaction it will become frozen, and may be kept in the solid state for several hours. Or otherwise, having introduced mercury into the large bulb of a thermometer, and attached the stem to the sliding rod of the receiver, place this over the sulphuric acid and water cup on the air-pump plate. After the air has been rarefied about fifty times, let the bulb be dipped repeatedly into the very cold but unfrozen water, and

again drawn up about an inch. In this way it will become incrustated with successive coats of ice, to the twentieth of an inch thick. The cup of water being now withdrawn from the receiver, the pendent icicle cut away from the bulb, and the surface of the ice smoothed with a warm finger, the receiver is again to be replaced, and the bulb being let down within half an inch of the acid, the exhaustion must be pushed to the utmost. When the syphon-gauge arrives at the tenth of an inch, the icy crust opens with fissures, and the mercury, having gradually descended in the tube till it reach its point of congelation, or 39° below zero, sinks by a sudden contraction almost into the cavity of the bulb. The apparatus being now removed, and the ball speedily broken, the metal appears a solid shining mass, that will bear the stroke of a hammer. A still greater degree of cold may be produced, by applying the same process to cool the atmosphere which surrounds the receiver.

When the acid has acquired one-tenth of water, its refrigerating power is diminished only one-hundredth. When the quantity of moisture is equal to one-fourth of the concentrated acid, the power of generating cold is reduced by a twentieth; and, when the dilution is one-half, the cooling powers become one-half or probably less. Sulphuric acid is hence capable of effecting the congelation of more than twenty times its weight of water, before it has imbibed nearly its own bulk of that liquid, or has lost about one-eighth of its refrigerating power. The acid should then be removed, and reconcentrated by heat.

The danger of using a corrosive acid in unskillful hands may be obviated by using oatmeal, desiccated nearly to brownness before a kitchen fire, and allowed to cool in close vessels. With a body of this, a foot in diameter and an inch deep, professor Leslie froze a pound and a quarter of water, contained in a hemispherical porous cup. Muriate of lime in ignited porous pieces, may also be employed as an absorbent. Even mouldering trap or whinstone has been used for experimental illustration with success.

By the joint operation of radiation and evaporation, from the surface of water, the natives of India are enabled to procure a supply of ice, when the temperature of the air is many degrees above the freezing point. Not far from Calcutta, in large open plains, three or four excavations are made in the ground, about thirty feet square and two feet deep, the bottom of which is covered to the thickness of nearly a foot with sugar canes, or dried stalks of Indian corn. On this bed are placed rows of small unglazed earthen pans, about an inch and a quarter deep, and somewhat porous. In the dusk of the evening, during the months of December, January, and February, they are filled with soft water, previously boiled and suffered to cool. When the weather is very fine and clear, a great part of the water becomes frozen during the night. The pans are regularly visited at sunrise, and their contents emptied into baskets which retain the ice. These are now carried to a conservatory made by sinking a pit fourteen or fifteen feet deep, lined with straw under a layer of coarse blanketing. The small

sheets of ice are thrown down into the cavity, and rammed into a solid mass. The mouth of the pit is then closed up with straw and blankets, and sheltered by a thatched roof.

COLDENIA, in botany, a genus of the tetragynia order, the tetrandria class of plants: cal. tetraphyllous: cor. funnel-shaped; styles four; seeds two, bilocular. There is but one species, a native of India. It is an annual plant, whose branches trail on the ground, extending about six inches from the root. They are adorned with small blue flowers, growing in clusters, which come out from the wings of the leaves. They are propagated by seeds sown on a hot bed; when the plants come up, they may be removed each into a separate pot, and plunged into a hot bed of tanner's bark, where they are to remain constantly.

CODDING, or **KOLDING** a small town of Jutland, formerly the residence of the Danish kings and a considerable sea-port, but its harbour is now so choked with sand that its navigation is completely destroyed. Its castle on a hill, is a place of much importance being situated near the Sleswick frontier from which town it is but sixty-two miles distant. Lat. 55° 30' N., long. 9° 29' E.

COLDINGHAM, a parish of Scotland, in Berwickshire, nearly seven miles long and as many broad, but of a very irregular figure. It was formerly one great common, but was divided among the proprietors, about 1773, by authority of the Court of Session.

COLDINGHAM, a town in the above parish, supposed to be the Colonia of Ptolemy, and called by Bede the city of Colud, Coludum and Coldana. It was famous many ages ago for its convent which was the oldest nunnery in Scotland; for here Ethelreda took the veil in 1070. From the ancient name, Coludum, it would seem that it had been formerly inhabited by the religious called Culdees. In 870 it was destroyed by the Danes, but its name has been rendered immortal by the heroism of its nuns; who, to preserve themselves inviolate from those invaders, cut off their lips and noses; and thus rendering themselves objects of horror, were, with their abbess Ebba, burnt in the monastery by the disappointed savages. After this it lay deserted, till the year 1098, when king Edward founded on its site a priory of benedictines in honor of St. Cuthbert, and bestowed it on the monks of Durham. It has fairs, 25th July, and 24th of October. It is two miles and a half north-west of Eyemouth, and eight N. N. W. of Berwick.

COLDITZ, a town of Germany, in the circle of Leipsic, seated on the Mulda, ten miles north-east of Leipsic. It was several times pillaged by the Swedes and Hussites, during the civil wars of Germany, in the seventeenth century.

COLDSTREAM, a town of Scotland seated on the Tweed, over which it has a fine stone bridge to Cornhill in England. Here General Monk fixed his head quarters before he marched into England to restore Charles II. and raised that regiment, which is still called the Coldstream regiment of Guards. Few towns are better situated than Coldstream for manufactures. The banks of the Tweed are rich in corn and cattle, and coals are cheap. The roads from Berwick

to London, from Berwick to Kelso, and from Dunse to England, all pass through the town. The excellence of the wool from the neighbouring district, points out the woollen manufacture as being adapted to the place. No extensive trade, however, is carried on. It has fairs, 30th July and 12th November. It is 332 miles and a half north of London, and eleven south-west of Berwick.

COLE (Henry) D. D. was a native of Gadshill in the Isle of Wight, and elected from Winchester school to a fellowship at New College, Oxford. Having graduated as a bachelor of civil law he visited Italy, and on his return practised in the court of Arches. He obtained under Henry the VIIIth, the living of Chelmsford in Essex, with a stall in St. Paul's cathedral, and an archdeaconry; together with the wardenship of his college, to which he was elected in 1542, with the living of Newton Longueville, Bucks. In the next reign, however, he honestly sent in a resignation of his benefices: from his objections to the reformed doctrine of the Church, a circumstance not forgotten by Queen Mary, who made him provost of Eton, dean of St. Paul's, and judge of the court of Arches. He preached at Archbishop Cranmer's execution, and was deprived of all his appointments by Queen Elizabeth. He died in prison in 1519.

COLE (Thomas), an eminent dissenting minister of the seventeenth century. He was educated at Westminster school, from whence he was elected student of Christ Church, Oxford, where he took his degree of M. A. In 1656 he was appointed principal of St. Mary Hall, where he was tutor to Locke. At the Restoration he was ejected for non-conformity, upon which he opened an academy at Nettlebed, but afterwards removed to London, where he settled, and became one of the lecturers at Pinner's Hall. He died in 1697. He wrote a Discourse on Regeneration, Faith, and Repentance, 8vo.; a Discourse of the Christian Religion in Sundry Points, 8vo.; the Incomprehensibility of imputed Righteousness by Human Reason, &c. 8vo.; and other tracts.

COLEBROOK, a rough hilly township of the United States, on the north line of Connecticut, in Litchfield county, thirty miles north-west of Hartford city. It was settled in 1756. Here are two iron works, and several mills, on Still river, a north-west water of Farmington river. In digging a cellar in this town, in 1796, the workmen, at the depth of about nine or ten feet, found three large tusks and two thigh bones of an animal, the latter of which measured each about four feet four inches in length, and twelve inches and a half in circumference. When first discovered they were entire, but as soon as they were exposed to the air they mouldered to dust. This adds another to the many facts which prove that a race of enormous animals, now extinct, once inhabited North America.

COLEBROOK DALE, a winding valley in the eastern part of Shropshire, on the banks of the Severn, between two vast mountains, which divide in various romantic forms, and are covered with beautiful hanging woods. In making a navigable canal to the Severn, in 1787, several springs of excellent native tar, or petroleum, were

here discovered, which, though now much reduced, flowed so copiously at first, as to afford from seventy to eighty gallons per day; so that barrels could hardly be got ready fast enough to barrel it up. A spring of brine was also discovered, as strong as most of that used for making salt. A work for obtaining mineral tar, from the condensed smoke of pit-coal, has been erected, and the most extensive iron works in England are established in this dale; which, with the bridge of cast iron over the Severn, add much to the natural romantic scenery of the place. 'The noise of the forges, mills, &c. (says Mr. Young) with all their vast machinery; the flames bursting from the furnaces, with the burning of coal, and the smoke of the lime kilns, are altogether horribly sublime.' The iron bridge was erected in 1779; the road over it, made of clay and iron flag, a foot deep, is twenty-four feet wide; the span of the arch is 100 feet six inches; and the height from the base to the centre forty feet. The weight of iron in all is 178 tons and a half.

COLEOPTERA, or beetle, the name of Linnaeus's first order of insects, thus ordinarily characterised, wings four, the upper crustaceous:—with a straight suture: giving the appearance of being covered with crustaceous shells. See **ENTOMOLOGY**.

COLERAIN, a large town of Ireland, in the county of Londonderry and province of Ulster, seated on the river Bann, four miles south of the coast. It was formerly a place of great consideration, being the chief town of a county erected by Sir John Perrot, during his government of Ireland; whereas it is now only the head of one of the baronies in the county of Londonderry; but it is still a corporation, and sends one member to the Imperial Parliament. It is very elegantly built. The port is indifferent, occasioned by the extreme rapidity of the river, which repels the tide, and makes the coming up to the town difficult; so that it has little trade, except its valuable salmon fishery, which amounts to some thousand pounds a year. Colerain is twenty miles north-east of Londonderry, and 114 from Dublin.

COLERAIN, a town of the United States in Georgia, on the north bank of St. Mary's river, Camden county, about forty-five miles from its mouth. On the 29th of June, 1796, a treaty of peace and friendship was concluded at this place, between the United States on one part, and the chiefs and warriors of the Creek nation on the other.

COLES (Elisha), a native of Northamptonshire, was born about the commencement of the seventeenth century, and embarked in trade, but afterwards became manciple at Magdalen College, Oxford, under the commonwealth. The Restoration displaced him; he however obtained a clerkship in the service of the East India Company. He published a highly Calvinistic work in favor of the doctrine of predestination, which is still held in estimation by the sect to which he belonged. He died in 1688.

COLES (E.), nephew of the above, was born in the same county, about the year 1640, and entered of the college of which his relation was a retainer. After the Restoration he first supported himself by private tuition in London, then be-

came usher at Merchant Tailors' school; but lost the situation by some alleged misconduct. Little of the particulars of his life is known; he died in Ireland in 1680, having compiled two dictionaries; one of his vernacular language, the other of Latin and English, with a correspondent rendering of English into Latin. Also *The Young Scholar's best Companion*; *A Hieroglyphical Bible for Youth*; *A Natural Method of Learning Latin*, 8vo.; *The complete English Schoolmaster*, 8vo.; *A System of Stenography*; a treatise bearing the whimsical title of *Nolens Volens, or you shall make Latin whether you will or no*; and a *Harmony of the Evangelists*.

CO'LESEED, *n. s.* From cole and seed. Cabbage seed.

Where land is rank, it is not good to sow wheat after a fallow; but *coleseed* or barley, and then wheat.

Mortimer.

COLE-SEED, the seed of the *napus sativa*, or long-rooted, narrow leaved rape, called in English *navew*, and reckoned by Linnaeus among the brassicas or cabbage kind. See **BRASSICA**. This plant is cultivated to great advantage in many parts of England, on account of the rape oil expressed from its seeds. The practice of sowing it was first introduced by those Germans and Dutchmen who drained the fens of Lincolnshire; and hence the notion has generally prevailed, that it will thrive only in a marshy soil; but this is now found to be a mistake. In preparing the land, care must be taken to plough it in May, and again about midsummer, making the ground as fine and even as possible. It must be sown the very day of the last ploughing, about a gallon on an acre. In January, February, and March, it affords good food for cattle, and will sprout again when cut; after which it is excellent nourishment for sheep. If it is not too closely cropped, it will, after all, bear seed in July. The same caution, however, is requisite with this food as with clover, till cattle are accustomed to it, as it is apt otherwise to swell them. When cultivated solely for the seed, it must be sown on deep strong land without dung, and must stand till one-half of the seeds at least are turned brown; which will be earlier or later, according to the season. In this state it is to be cut like wheat, and with the same care. Every handful as it is cut should be regularly ranged on sheets, that it may dry leisurely in the sun, which will commonly be in a fortnight; after which it must be carefully threshed out, and carried to the mill for expressing the oil. The produce of cole-seed is generally from five to eight quarters on an acre.

COLES-HILL, a market town of Warwickshire, seated on the Colne, at the side of a hill. It consists of one long street, with a smaller one branching from the middle towards the churchyard, which is on the summit of the eminence. The church is a very old structure, with a handsome decorated Gothic tower and spire. It has a market on Wednesday. It is eleven miles north-west of Coventry, and 104 from London.

COLESHEY, a town of Southern India, in the province of Travancore. Here is a small harbour, where ships are secured from north and east winds, by the shelter of some rocks. The

Danes formerly had a small factory here. Long. 77° 11' E. lat. 8° 12' N.

COLET (John), D. D., dean of St. Paul's, and son of Henry Colet, knight, was born in London in 1466. He was sent to Magdalen College, Oxford, where he remained seven years. About 1493 he went to Paris, and thence to Italy. On his return to England in 1497 he took orders, and read lectures gratis at Oxford, on the epistles of St. Paul. At this time he possessed the rectory of Dennington, and was also prebendary of York, and canon of St. Martin's le Grand. In 1502 he became prebendary of Sarum; prebendary of St. Paul's in 1515; and immediately after dean of that cathedral, having taken the degree of D. D. He was also chaplain to Henry VIII. He introduced the practice of preaching and expounding the Scriptures; and soon after established a perpetual divinity lecture in St. Paul's church, three days in the week; an institution which paved the way for the reformation. About 1508 dean Colet formed his plan for the foundation of St. Paul's school, which he completed in 1512, and endowed with estates, which now amount to a very large sum. In his station he so labored to restore discipline as to bring upon himself the charge of heresy; the clergy, whom he attempted to reform, became his enemies, and bishop Fitzjames complained of him to Warham, archbishop of Canterbury, who dismissed him without a hearing. Being seized with the sweating sickness, he died in 1519, aged fifty-three. He wrote, 1. Rudimenta Grammaticæ; 2. The Construction of the Eight Parts of Speech; 3. Daily Devotions; 4. Epistolæ ad Erasmus; 5. Several sermons; and other works which still remain in MS.

COLLEWORT, *n. s.* Sax. cabbyne. A species of cabbage.

The decoction of the roots is also recommended to bathe them. *Wittemer or Eryngium.*

She took the flowers which her bus and gown
From his own ground a small well-watered spot;
She stripped the stalks of all their leaves, the best
She culled, and then with handy care she dressed.

Dryden.

How turnips hide their swelling heads below,
And how the closing leaves upward grow. *Gray.*

COLEWORT. See BRASSICA.

COLFORD, a town in Gloucestershire or the borders of Monmouthshire, near which there are considerable iron-works. It has a market on Friday; fairs, June 20th, and November 24th. It is twenty-three miles W. S. W. of Gloucester, and 124 from London.

COLIBERTI, or COLBERTS, in law, were tenants in socage, and particularly such villeins as were manumitted or made freemen. But they had not an absolute freedom; for, though they were better than servants, yet they had superior lords to whom they paid certain duties, and, in that respect, might be called servants, though they were of middle condition between freemen and servants.

COLIBRI, a species of humming bird in Brasil. See TROCHILUS.

COLIC, *n. s. & a. f.* Lat. colicus. It strictly is a disorder of the colon: but loosely, any disorder of the stomach or bowels that is at-

tended with pain. There are four sorts: 1. A bilious colic, which proceeds from an abundance of acrimony or cholera irritating the bowels, so as to occasion continual gripes, and generally with a looseness; and this is best managed with lenitives and emollients. 2. A flatulent colic, which is pain in the bowels, from flatulæ and wind, which distend them into unequal and unnatural capacities; and this is managed with carminatives and moderate openers. 3. An hysterical colic, which arises from disorders of the womb, and is communicated by consent of parts to the bowels; and is to be treated with the ordinary hysterics. 4. A nervous colic, which is from convulsive spasms and contortions of the guts themselves from some disorders of the spirits, or nervous fluid, in their component fibres; whereby their capacities are, in many places, strengthened, and sometimes so as to occasion obstinate obstructions: this is best remedied by brisk cathartics, joined with opiates and emollient diluters. There is also a species of this distemper, which is commonly called the stone colic, by consent of parts, from the irritation of stone or gravel in the bladder or kidneys; and this is most commonly to be treated by nephritics and oily diuretics, and is assisted with the cruminateur serpentine clysters.

Colic of infants proceeds from acidity, and distends in the aliment expanding itself while the aliment ferments. *A. B. C. of the Art of Medicine.*

Intestine stone and ulcer, called pangs. *M. B. C.*

COLICA, in medicine, the colic, a well known disease; characterised by a pain in the belly, and a sensation like a twisting of the intestines, attended with vomiting and costiveness. This disease is classed by Cullen under the class neuroses, order spasmi. It is occasioned very frequently by the poison of white lead. See MEDICINE.

COLIGNI, Gaspard De', admiral of France, was born in 1516. He signalled himself in his youth, in the reigns of Francis I. and Henry II., and was made colonel of infantry, and admiral of France, in 1552. Henry II. employed him in the most important affairs; but, after the death of that prince, he embraced the reformed religion, and became the chief of the protestant party; he strongly opposed the house of Guise, and rendered this opposition so powerful, that it was thought he would have overturned the French government. On the peace made after the battles of Jarnac and Montcontour, Charles IX. deluded Coligni into security by his deceitful favors; and, though he recovered one attempt upon his life, when he attended the nuptials of the prince of Navarre, he was included in the dreadful massacre of the protestants on St. Bartholomew's Day, 1572, and his body treated with wanton brutality by a misguided popish populace. A party, headed by the duke of Guise, broke into his house, and one of the servants of the latter named Besme, drawing his sword, the admiral said calmly, 'young man, you ought to respect my gray hairs; but do as you please, you can only shorten my life a few days.' Besme stabbed him repeatedly, and throwing his body through the window, it was for three days exposed to the in-

sults of the mob, and hung by the feet upon a gibbet. It was at length taken down by his cousin Montmorency, and buried in the chapel of Chantilly. Catherine de Medicis had his head embalmed, and sent as a present to Rome.

COLIMA, a small town of Mexico, situated in a large fertile valley of the same name, which produces cocoa, cassia, and sometimes gold. Near this town is a volcano with two peaks, from both of which smoke continually issues, and it occasionally belches forth flames. According to Dampier, this mountain is in lat. $18^{\circ} 54' N.$, and long. $103^{\circ} 24' W.$ The town is included in the intendency of Guadaluca, and is 451 miles west from Mexico.

COLIN, or **KOLLIN**, a town of Bohemia, on the Elbe, with a castle of considerable strength. Garnets and topazes are procured in the neighbourhood, the polishing, &c., of which give employment to many of the inhabitants. Near here is the castle of Chotzemitz, where was fought the celebrated battle of that name between the Austrians and Prussians, June 18th, 1757. Colin is included in the circle of Kaurzim, and is twenty-eight miles east of Prague.

COLOURE, a small, but ancient and strong, town of France, in the department of Eastern Pyrenees, with a small port on the Mediterranean, defended by a castle on a rock. It is chiefly inhabited by fishermen. It was taken by the Spaniards in December, 1793, but surrendered to the French, with all its artillery and stores, after a siege of nineteen days, on the 26th of May, 1794. The national convention decreed that a column should be erected on the spot, in memorial that 'here 7000 Spaniards laid down their arms before the republicans.' It is five leagues south east of Perpignan, and five east of Ceret.

COLISEUM, the amphitheatre built at Rome by Vespasian. See **AMPHITHEATRE** and **CIRCUS**.

COLITES, in natural history, a name given by some writers to a kind of pebble, found in the shape of the human penis and testes, either separately or together.

COLLAERT (Adrian), an eminent engraver who flourished about 1550, born at Antwerp. After having learned the principles of engraving, he went to Italy. He worked entirely with the graver, in a firm neat style, but rather stiff and dry. The vast number of plates executed by him evince the facility with which he engraved; but though exceedingly neat, they are seldom highly finished.

COLLAERT (John), the son of Adrian, was also an excellent artist. He drew and engraved in the style of his father; and was equal to him in merit. He must have been very old when he died; for his prints are dated from 1555 to 1622. He assisted his father, and engraved besides a prodigious number of plates on various subjects. One of his best prints is Moses striking the rock, lengthwise, from Lambert Lombard. A great number of small figures are introduced into this print; and they are admirably well executed: the heads are fine, and the drawing very correct.

COLLAHUAS, a province of Peru, South America, bounded on the north by that of Chumbivilcas, east by that of Cines and Canches,

south-east by that of Lampa, south by that of Arequipa, and west by that of Camana. It is fifty-two leagues in length, south-east and north-west, and sixteen wide. Being situated in the Andes, its general temperature is bleak, but that part which borders on Camana is mild. The valleys produce wine, brandies, maize, wheat, pulse, and figs, which are preserved extensively as food. Other parts of this province feed large and small cattle, and native sheep. The whole province is very rocky, and the roads ill contrived and rough. It is rich, however, in silver mines, which are of great depth. Here are also gold, tin, lead, copper, and sulphur mines. The capital is Cailloma.

COLLAPSE, *n. s.* \int Lat. *collabor*, *collapsio*, *n. s.* \int *sis*. To fall together; to close so as that one side touches the others. The act of closing; the state of vessels closed.

In consumptions and atrophy the liquids are exhausted, and the sides of the canals *collapse*; therefore the attrition is increased, and consequently the heat. *Arbutnot on Dict.*

COLLAR, *n. s.* & *v. a.* Lat. *collare*; Fr. *collier*. Whatever encloses the neck, even the clavicle, the bones on each side the neck are called the collar-bone; that which surrounds the neck of whatever constructed, and for whatever purpose worn, is the collar. To slip the collar is to get free, to disentangle from the collar, but this applies to collar only when it is the badge or instrument of slavery and drudgery. To collar is to seize by the collar, or the throat. But both the noun and verb are used in a different sense, as derived from Fr. *lier*, *colier*, Lat. *colligare*, it is applied to meat tied together to be cooked. A collar of brawn is the quantity bound up in one parcel. To collar beef, or other meat is to roll it up, and bind it hard and close with a string or collar.

The tapes of her white volupere,
Were of the same suit of hire *colere*.

Chaucer's Canterbury Tales.

When, as the ape him heard so much to talk
Of labour, that did from his liking baulk,
He would have slipt the *collar* handsomely.

Hubbert's Tale.

Her waggon spokes made of long spinners' legs,
The traces of the smallest spider's web,
The *collars* of the moonshine's watery beams.

Shakespeare.

He bore the majesty of a mighty emperor; his crown and sceptre of pure gold, a *collar* of pearls about his neck, his garment of crimson velvet, embroidered with precious stone and gold.

Milton. Hist. Mosco.

And ghostly Charles turning his *collar* low,
The purple thread about his neck doth show.

Marell.

Ten brace and more of greyhounds;
With golden muzzles all their mouths were bound,
And *collars* of the same their neck surround.

Dryden's Fables.

That's nothing, says the dog, but the fretting of my *collar*: nay, says the wolf, if there be a *collar* in the case, I know better things than to sell my liberty.

L'Estrange.

A page riding behind the coach, fell down, bruised his face, and broke his right *collar-bone*.

Wiseman's Surgery.

Headlong he falls, and on the rugged stone,
Distorts his neck, and cracks the collar-bone. *Gay.*

COLLAR, in Roman antiquity, a sort of chain put generally round the necks of slaves who had run away after they were taken, with an inscription round it, intimating their being deserters, and requiring their being restored to their proper owners, &c.

COLLAR, in the modern sense, an ornament consisting of a chain of gold, enamelled, frequently set with ciphers or other devices, with the badge of the order hanging at the bottom, worn by the knights of several national orders over their shoulders, on the mantle, and its figure drawn round their armories. See **HERALDRY** and **ORDERS**.

COLLAR, KNIGHTS OF THE, a military order in the ci-devant republic of Venice, called also the order of St. Mark, or the Medal. The doge and the senate conferred this order; the knights bore no particular habit, only the collar, which the doge put around their necks, with a medal, wherein was represented the winged lion of the republic.

COLLAR OF A DRAUGHT HORSE, a part of harness made of leather and canvas, and stuffed with straw or wool, to be put about the horse's neck.

COLLATE, *v. a.* } Lat. *conficere, collatura.*

COLLATION, *n. s.* } To compare one thing of

COLLATOR, *n. s.* } the same kind with another, as copies and manuscripts. To bestow, to confer.

Knowledge will be ever a wandering and indigested thing, if it be but a commixture of a few notions that are at hand and occur, and not excited from a sufficient number of instances, and those well *collated*.

Bacon's Nat. Hist.

They could not relinquish their Judaism, and embrace Christianity, without considering, weighing, and *collating* both religions. *South.*

The significance of the sacrament disposes the receiver to admit the grace of the Spirit of God, there consigned, exhibited and *collate*d.

Taylor's Communicant.

A mandatory cannot interrupt an ordinary *collator*, till a month is expired from the day of presentation.

Ayliffe.

To read the titles they give an editor or *collator* of a manuscript, you would take him for the glory of letters. *Addison.*

He thrust out the invader, and *collated* Amsdorf to the benefice: Luther performed the consecration. *Atterbury.*

Neither are we to give thanks alone for the first *collation* of these benefits, but also for their preservation. *Ray on the Creation.*

In the disquisition of truth, a ready fancy is of great use; provided that *collation* doth its office.

Greac's Cosmology.

I return you your Milton, which, upon *collation*, I find to be revised and augmented in several places.

Pope.

COLLATERAL, *adj.* } Lat. *con* and *latus.*

COLLATERALLY, *adv.* } Side to side, running parallel; diffused on either side. In genealogy, those that stand in equal relation to some common ancestor; not direct, not immediate, concurrent.

They shall hear and judge 'twixt you and me;

If by direct or by *collateral* hand

They find us touched, we will our kingdom give

To you in satisfaction.

Shakspeare.

In his bright radiance and *collateral* light

Must I be comforted, not in his sphere. *Id.*

Thus saying, from his radiant seat he rose

Of high *collateral* glory. *Milton.*

But man by number is to manifest

His single imperfection; and beget

Like of his like, his image multiplied

In unity defective, which requires

Collateral love and dearest amity. *Id.*

These pullies may be multiplied according to sundry different situations, not only when they are subordinate, but also when they are placed *collaterally*.

Wilkins.

By asserting the scripture to be the canon of our faith, I have created two enemies: the papists more directly, because they have kept the scripture from us; and the fanatics more *collaterally*, because they have assumed what amounts to an infallibility in the private spirit. *Dryden.*

The estate and inheritance of a person dying intestate, is, by right of devolution, according to the civil law, given to such as are allied to him, *ex latere*, commonly styled *collaterals*, if there be no ascendants or descendants surviving at the time of his death.

Ayliffe's Parerg. n.

All the force of the motive lies within itself: it receives no *collateral* strength from external considerations. *Atterbury.*

COLLATERAL RELATIONS, in genealogy, those who proceed from the same stock, not in the same line of ascendants or descendants, but being, as it were, aside of each other. Thus, uncles, aunts, nephews, nieces, and cousins, are *collaterals*, or in the same *collateral* line: those in a higher degree, and nearer the common root, represent a kind of paternity with regard to those more remote. See **GENEALOGY**.

COLLATIA, a town of the Sabines; thought to be distant between four and five miles east from Rome: situated on an eminence, upon the Anio. It existed in Cicero's time, but in Strabo's day was only a village; no trace now remains of it.

COLLATINA PORTA: from *Collatia*; a gate of Rome, at the Cullis Hortulorum, afterwards called Pinciana, from the Pincii, a noble family.

COLLATINUS (L. Terquinius), the husband of the celebrated Lucretia, and one of the first two consuls of Rome. He was a native of *Collatia*. See **ROME, HISTORY OF**.

COLLATION, *n. s.* In law, it is applied also to a repast; a treat less than a feast.

Collation is the bestowing of a benefice, by the bishop that hath it in his own gift or patronage; and differs from institution in this, that institution into a benefice is performed by the bishop at the presentation of another who is patron, or hath the patron's right for the time. *Cowell.*

COLLATION, in canon law, differs from a common presentation, as it is the giving of the church to the person, while presentation is the giving of the person to the church. But *collation* supplies the place of presentation and institution; and amounts to the same as institution where the bishop is both patron and ordinary. Anciently the right of presentation to all churches was in the bishop; and now if the patron neglect to

present to a church, then this right returns to the bishop by collation: if the bishop neglect to collate within six months after the elapse of the patron, then the archbishop has a right to do it; and, if the archbishop neglect, then it devolves to the king; the one as superior, to supply the defects of bishops, the other as supreme, to supply the defects of government.

COLLATION, in common law, the comparison of a copy with its original, to see if it be conformable; or the report or act of the officer who made the comparison. A collated act is equivalent to its original, provided all the parties concerned were present at the collation.

COLLATION, in Scots law, that right which an heir has of throwing the whole heritable and moveable estates of the deceased into one mass, and sharing it equally with the others in the same degree of kindred, when he thinks such share will be more than the value of the heritage to which he had an exclusive title.

COLLATION is used among the Romanists for the meal made on a fast-day, in lieu of a supper. Only fruits are allowed in a collation: F. Lorraineau observes, that anciently there was not allowed even bread in the collations in Lent, nor any thing beside a few comfits and dried herbs and fruits; which custom, he adds, obtained till A.D. 1513. Cardinal Humbert observes further, that in the middle of the eleventh century there were no collations at all allowed in the Latin church in the time of Lent; and that the custom of collations was borrowed from the Greeks, who themselves did not take it up till about the eleventh century.

COLLATITIOUS, *adj.* Lat. *collaticius*. Done by the contribution of many.

COLLAUD, *v. a.* Lat. *collaudo*. To join in praising.

COLLEAGUE, *n. s. & v. a.* Lat. *collega*. A partner in office and employment. To unite with, is the general sense of the verb.

Collegued with this dream of his advantage,
He hath not failed to pester us with message,
Importing the surrender of those lands.

Shakespeare. Hamlet.

Easy it might be seen that I intend

Mercy *colleague* with justice sending thee. *Milton.*

The regents, upon demise of the crown, would keep the peace without *colleaguus*. *Swift.*

COLLECT, *v. a.* Lat. *colligo, collectum, collectamus, collectitius, collector.*
COLLECTA'NEOUS, *adj.*
COLLECTEDLY, *adv.*
COLLECTIBLE, *adj.*
COLLECTION, *n. s.*
COLLECTIOUS, *adj.*
COLLECTIVE, *adj.*
COLLECTIVELY, *adv.*
COLLECTOR, *n. s.*

The primary sense, which runs through all its multiplied derivatives, is that of gathering or bringing together. When applied to the mind, it is bringing the thoughts on any given subject to a focus; a man collects himself when he assembles his sentiments, and recovers, by summoning together the powers of his mind, the self-command of which surprise or fear had deprived him. When applied to the exercise of the reasoning faculty, it signifies to infer, as a consequence from arguments and facts, collected and brought together. It refers to the aggregate of things taken together, and never to

the detail; to the entire body composed of parts, but not to the parts individually and separately. In grammar, a collective noun is a word which expresses a multitude, though itself be singular; as, a company; an army.

The whole revolution of ages from everlasting to everlasting is so *collectedly* and presentieckly represented to God. *More.*

It should be a weak *collection*, if whereas we say, that when Christ had overcome the sharpness of death, he then opened the kingdom of heaven to all believers; a thing in such sort affirmed with circumstances, were taken as insinuating an opposite denial before that circumstance be accomplished. *Hooker.*

Although we cannot be free from all sin *collectively*, in such sort that no part thereof shall be found in us, yet distributively all great actual offences, as they offer themselves one by one, both may and ought to be by all means avoided. *Id.*

A body *collective*, it containeth a huge multitude. *Id.*

Singly and apart, many of them are subject to exception, yet *collectively* they make up a good moral evidence. *Hale.*

Be collected;

No more amazement. *Shakspeare. Tempest.*

Affrighted much,

I did in time *collect* myself, and thought
This was so, and no slumber. *Id. Winter's Taks.*

This label

Is so from sense in hardness, that I can
Make no *collection* of it *Id. Cymbeline.*

The reverend care I bear unto my lord,
Made me *collect* these dangers in the duke. *Id. Henry VI.*

When she, from sundry arts, one skill doth draw;
Gathering from divers flight, one act of war;
From many cases, like one rule of law;

These her *collections* not the senses are. *Davies.*

Whether thereby be meant Euphrates, is not *collectible* from the following words.

Browne's Vulgar Errors.

Antiquity has left many falsities controllable not only by critical and *collective* reason, but contrary observations. *Browne.*

As when of old some orator renowned
In Athens or free Rome, where eloquence
Flourished, since mate, to some great cause addressed
Stood in himself *collected*, while each part,
Motion, each act won audience, ere the tongue
Sometimes in height began, as no delay
Of preface breaking through his zeal of right. *Milton.*

They conclude they can have no idea of infinite space, because they can have no idea of infinite matter; which consequence, I conceive, is very ill *collected*. *Locke.*

Let a man *collect* into one sum as great a number as he pleases, this multitude, how great soever, lessens not one jot the power of adding to it. *Id.*

The peers, therefore, sit in parliament in their *collective*, the commons, in their representative body. *Bollingbroke.*

The three forms of government differ only by the civil administration being in the hands of one or two, called kings; in a senate, called the nobles; or in the people *collective* or representative, who may be called commons. *Swift.*

The best English historian, when his style grows antiquated, will be only considered as a tedious relater of facts, and perhaps consulted to furnish materials for some future *collector*. *Id.*

The commissions of the revenue are disposed of, and the collectors are appointed by the commissioner.

Volumes without the collector's own reflections. *Sicif.*
Addisen.

The gallery is hung with a collection of pictures. *Id.*

Here, like the bee, that on industrious wing,
Collects the various odours of the spring;
Walkers at leisure, learning's flowers may spoil,
Nor watch the wasting of the midnight oil. *Gay.*

A great part of this treasure is now embellished, lavished, and feasted away by collectors, and other officers. *Temple.*

Nor perjured knight desires to quit thy arms.
Fairer collection of thy sex's charms. *Prior.*

'Tis memory alone that enriches the mind, by preserving what our labour and industry daily collect. *Watts.*

COLLECT, *n. s.* Lat. *collecta*. A short comprehensive form of prayer, used at the sacrament; any short prayer.

Then let your devotion be humbly to say over proper collects. *Taylor's Guide to Devotion.*

COLLECT, in the liturgy of the church of England, and the mass of the Roman Catholics, denotes a prayer, accommodated to any particular day, occasion, or circumstance. See LITURGY, and MASS. In general, all the prayers in each office are called collects; either because the priest speaks in the name of the whole assembly, whose sentiments and desires he sums up by the word *cremus*, 'let us pray,' or because these prayers are offered when the people are assembled together. The congregation itself is in some ancient authors called collect. The popes Gelasius and Gregory are said to have been the first who established collects. Despence, of Paris, wrote a treatise on collects, their origin, antiquity, &c. Collect is sometimes also used for a tax, or imposition, raised by a prince for any pious design. Thus, in 1166, the king of England, coming into Normandy, appointed a collect for the relief of the holy land.

COLLEGATARY, *n. s.* Lat. *collegatus* and *legatum*, a legacy. In the civil law, a person to whom is left a legacy in common with one or more other persons.

COLLEGE, *n. s.* Lat. *collegium*. A community; a number of persons living by some common rules.

On barbed steeds they rode in proud array,
Think as the college of the bees in May. *Dryden.*

A society of men set apart for learning or religion.

He is returned with his opinions,
Gathered from all the famous colleges,
Almost in Christendom, *Subjunctive.* Henry VIII.
I would the college of the cardinals
Would choose him pope, and carry him to Rome. *Id.*

This order or society is sometimes called Solomon's house, and sometimes the college of the six days' work. *Bacon.*

The house in which the collegians reside.

Huldah, the prophetess, dwelt in Jerusalem in the college. *Kings.*

A college, in foreign universities, is a lecture read in public.

COLLEGES, ANCIENT. Colleges, among the Romans, embraced, indifferently, those employed in

the offices of religion, of government, the liberal, and even mechanical arts and trades; so that, with them, the word signified what we call a corporation or company. They had not only the college of augurs, and the college of capitolini, i. e. of those who had the superintendance of the capitoline games; but also colleges of artificers, *collegia artificum*: of carpenters, *fabricatorum*, or *fabrorum tignariorum*: of potters, *figulorum*; of founders, *arariorum*; of locksmiths, *fabrorum ferrariorum*; of engineers, *tignariorum*; of butchers, *laniorum*; of dendrophori, *dendrophororum*; of centonaries, *centonariorum*; of makers of military casques, *sagariorum*; of tent makers, *tabernaculariorum*; of bakers, *pistorum*; of musicians, *tubicinum*, &c. Plutarch observes, that Numa first divided the people into colleges; that each consulting the interests of their colleges, whereby they were divided from the citizens of the other colleges, they might not enter into any general conspiracy against the public repose. Each of these colleges had distinct halls; and likewise, in imitation of the state, a treasury and common chest, a register, and one to represent them upon public occasions, and statutes-like acts of parliament. These colleges had the privilege of manumitting slaves, of being legatees, and making by-laws for their own body, provided they did not clash with the laws of the republic.

COLLEGE, is used, in modern times, for a public place endowed with certain revenues, where the several parts of learning are taught. An assemblage of several of these colleges constitutes an university. The erection of colleges is part of the royal prerogative. The establishment of colleges or universities is a remarkable period in literary history. The schools in cathedrals and monasteries confined themselves, chiefly, to the teaching of grammar. There were only one or two masters employed in that office. But, in colleges, professors are appointed to teach all the different parts of science. The first obscure mention of academical degrees in the university of Paris (from which the other universities in Europe have borrowed most of their customs and institutions), occurs A.D. 1215. We notice the most celebrated institutions of this kind in Great Britain, and a few of the more conspicuous modern ones.

COLLEGE, GRESHAM, OR COLLEGE OF PHILOSOPHY, a college founded by Sir Thomas Gresham, and endowed with the revenue of the Royal Exchange; one moiety of this endowment the founder bequeathed to the mayor and aldermen of London and their successors, in trust, that they should find four able persons to read, within the college, lectures on divinity, geometry, astronomy, and music; who are chosen by a committee of the common council, consisting of the lord mayor, three aldermen, and eight commoners, and allowed each, besides lodging, £50 per annum. The other moiety he left to the company of Mercers, to find three more able persons, chosen by a committee of that company, consisting of the master and three wardens, during their office, and eight of the court of assistants, to read lectures on law, physic, and rhetoric, on the same terms; with this limitation, that the several lecturers should read, in term

time, every day in the week except Sundays; in the morning in Latin, in the afternoon the same in English; but that in music to be read only in English. By the eighth of George III. cap. 32, the building appropriated to this college was taken down, and the excise office erected in its room. Each of the professors is allowed £50 per annum, in lieu of the apartments, &c. relinquished by them in the college, and is permitted to marry, notwithstanding the restriction of Sir Thomas Gresham's will. The lectures are now read in a room over the Royal Exchange; and the City and Mercers' company are required to provide a proper place for this purpose.

COLLEGE OF CIVILIANS, commonly called **Doctors' Commons**; a college founded by Dr. Harvey, dean of the Arches, for the professors of the civil law residing in London; where usually, likewise, reside the judges of the arches court of Canterbury, judge of the admiralty, of the prerogative court, &c. with other civilians, who all live, as to diet and lodging, in a collegiate manner, communing together; whence the appellation of **Doctors' Commons**. Their house being consumed in the great fire, they all resided at Exeter-house in the Strand till in 1672; when their former house was rebuilt, at their own expense, in a very splendid manner. To this college belong thirty-four proctors, who make themselves parties for their clients, manage their causes, &c.

COLLEGE OF HERALDS, OR COLLEGE OF ARMS, is a corporation founded by king Richard III., who, by charter bearing date the 2nd of March, in the first year of his reign, made the kings, heralds, and pursuivants of arms, one body corporate by the name of 'Le garter regis armorum Anglicorum, regis armorum partium australium, regis armorum partium borealium, regis armorum wallie, et heraldorum, prosectorum, sive pursevandorum armorum;' empowered them to have and use a common seal, and granted to them and their successors, for the use of the twelve principal officers of the corporation, a house with its appurtenances, then called *Colde Arbor*, and situated within the parish of All-Hallows the Less, in the city of London; they finding a chaplain to celebrate mass daily in the said house, or elsewhere at their discretion, for the good state of health of Anne the queen, and Edward, prince of Wales, during their lives, and for their souls after their decease. In consequence of the act of resumption, passed in the first year of the reign of king Henry VII., this house was seized into the king's hands, because it was supposed to belong personally to John Writhe, garter, who then lived in it, and not to the officers of arms in their corporate capacity.

During the reign of Henry VII. and Henry VIII., the officers of arms frequently petitioned the throne for a grant of some house or place wherein to hold their assemblies, but without success. King Edward VI., however, in a charter dated the 4th of June, in the third year of his reign, and by authority of parliament, endeavoured to make them some amends, by confirming to them all their ancient privileges, as to be free and discharged from all subsidies, in all realms where they take their demoure; as also from all

tolls, taxes, customs, impositions, and demands, as well from watch and ward, as from the election to any office of mayor, sheriff, bailiff, constable, scavenger, church-warden, or any other public office of what degree, nature, or condition soever.

Philip and Mary, by their charter bearing date the 18th day of July, in their first and second years, re-incorporated the kings, heralds, and pursuivants of arms by their former names; and to the intent that they might reside together, and consult and agree amongst themselves for the good of their faculty, and for the depositing and secure preservation of their records, inrolments, and other documents and papers, granted to them a messuage, with its appurtenances, called *Derby House*, situate in the parish of St. Benedict and St. Peter, within the city of London, and in the street leading from the south door of the cathedral church of St. Paul, to a place there called *Paul's Wharf*, and then late in the tenure of Sir Richard Sakevyle, knight, but theretofore parcel of the possessions of Edward, earl of Derby, and to be by the said corporation held in free burgage of the city of London. In the great fire of London, anno 1666, the college was entirely consumed: but the heralds had the good fortune to save all their muniments and books, which were deposited in the palace at Whitehall; from whence they were afterwards removed into the palace at Westminster, near to the court of requests, whereupon public notice was given in the London Gazette, that the herald's office was there kept. The college was afterwards rebuilt, and, as a regular quadrangular building, was considered one of the best designed and handsomest brick edifices in London, particularly the hollow archway of the great gate, which is esteemed a singular curiosity; but the college is now removed to the neighbourhood of Charing-cross.

The corporation consists of three kings of arms, Garter, Clarencieux, and Noroy, six heralds, viz. Windsor, Chester, Lancaster, Somerset, York, and Richmond, and four pursuivants, viz. Portcullis, Rouge-dragon, Bluemantle, and Rouge-Croix; who all take presidency according to the dates of their respective patents.

The arms of the college; argent, a cross gules between four doves rising azure. Crest. On a ducal coronet, or a dove rising azure. Supporters. Two lions rampant guardant Argent, ducally gorged or.

The COLLEGE OF HERALDS in Scotland, consists of Lyon king of arms, six heralds, and six pursuivants, and a number of messengers.

COLLEGE OF JUSTICE, the supreme civil court of Scotland; otherwise called the court of session, or of council and session. See SCOTLAND, LAW OF.

COLLEGE OF PHYSICIANS, a corporation of physicians in London, who by several charters and acts of parliament of Henry VIII. and his successors, have certain privileges, whereby no man, though a graduate in physic of any university, may, without licence under the said college seal, practice physic in or within seven miles of London; with power to administer oaths, fine and imprison offenders in that and several other particulars; to search the apothecaries shops, &c. in and about London, to see if their drugs, &c. be wholesome, and their compositions ac-

ording to the form prescribed by the said college in their dispensatory. By the said charter they are also freed from all troublesome offices, as to serve on juries, be constables, keep watch, provide arms, &c. The society had anciently a college in Knight-rider Street, the gift of Dr. Linacre, physician to king Henry VIII. Since that time they have had a house built for them by the famous Dr. Harvey in 1652, at the end of Amen-corner, which he endowed with his whole inheritance in his lifetime; but this being burnt in the great fire, in 1666, a new one was erected, at the expence of the fellows, in Warwick-lane, with a noble library, given partly by the marquis of Dorchester, and partly by Sir Theodore Mayerne. From this, as an inconvenient situation, the college has been removed to Pall Mall East, where a noble building has been erected on a site given by government. Of this college there are at present a president, four censors, eight electors, a register, and a treasurer, chosen annually in October; the censors have, by charter, power to survey, govern, and arrest, all physicians, or others practising physic, in or within seven miles of London; and to fine, amerce, and imprison them, at discretion. The number of fellows was anciently thirty, till king Charles II. increased their number to forty; and James II. giving them a new charter, allowed the number of fellows to be enlarged so as not to exceed eighty; reserving to himself and his successors the power of appointing and displacing any of them for the future. The college is not very rigorous in asserting their privileges; there being a great number of physicians, some of very good abilities, who practise in London, &c. without their licence, and are connived at by the college: yet by law, if any person not expressly allowed to practise, take on him the cure of any disease, and the patient die under his hand, it is deemed felony. In 1696 the college made a subscription, to the number of forty-two of their members, to set on foot a dispensary for the relief of the sick poor: since which they have erected two other dispensaries.

COLLEGE OF PHYSICIANS, EDINBURGH, was erected on the 29th of November 1681. The design of this institution was, to prevent the abuses daily committed by foreign and illiterate impostors, quacks, &c. For this reason, king Charles II. granted letters patent to erect into a body corporate and politic, certain physicians in Edinburgh and their successors by the title of the President and Royal College of Physicians at Edinburgh, with power to choose annually a council of seven, one whereof to be president: these are to elect a treasurer, clerk, and other officers; to have a common seal; to sue and be sued; to make laws for promoting the art of physic, and regulating the practice thereof, within the city of Edinburgh, town of Leith, and districts of the Canongate, Westport, Pleasance, and Potter-row; through all which the jurisdiction of the college extends. Throughout this jurisdiction, no person is allowed to practice physic, without a warrant from the college, under the penalty of £5 sterling the first month, to be doubled monthly afterwards while the offence is continued; one half the money

arising from such fines to go to the poor, the other to the use of the college. They are also empowered to punish all licentiates in physic, within these bounds, for faults committed against the institutions of the college; and to fine them of sums not exceeding 40s. On such occasions, however, they must have one of the bailies of the city to sit in judgment along with them, otherwise their sentence will not be valid. They are also empowered to search and inspect all medicines within their jurisdiction, and throw out into the street all such as are bad or unwholesome. That they may the better attend their patients, they are exempted from watching, warding, and serving on juries. They are, however, restrained from erecting schools for teaching the art of physic, or conferring degrees on any person qualified for the office of a physician; but are obliged to license all such as have taken their degrees in any other university, and to admit as honorary members all the professors of physic in the rest of the universities of Scotland. These privileges and immunities are not, however, to interfere with the rights and privileges of the apothecary surgeons, in their practice of curing wounds, contusions, fractures, and other external operations.

COLLEGE OF SURGEONS, ROYAL, LONDON, was incorporated by charter in 1800, under a master, two governors, and eighteen assistants. Its house is in Lincoln's-Inn-Fields. There is also at Edinburgh a Royal College of Surgeons of late institution, under a president, treasurer, and honorary fellows. This college is authorised for carrying into execution a scheme for providing for their wives and children, &c.; and for examining and licencing, if found qualified, all practitioners in surgery, within certain limits.

COLLEGE PRO PROPAGANDA FIDE, was founded at Rome in 1622, by Gregory XV. and enriched with ample revenues. It consists of thirteen cardinals, two priests, and a secretary; and was designed for the propagation of the Romish religion in all parts of the world. The funds of this college have been very considerably augmented by Urban VIII. and many private donations. Missionaries are supplied by this institution with a variety of books suited to their several appointments. Seminaries for their instruction are supported by it, as also a number of charitable establishments connected with, and conducive to, its main object.—Another college under this title was established by Urban VIII. in 1627, in consequence of the liberality of John Baptist Viles, a Spanish nobleman. This is set apart for the instruction of those who are designed for the foreign missions. It was at first committed to the care of three canons of the patriarchal churches; but ever since 1641 it is under the same government with the former institution.

COLLEGE, SIOX, or the college of the London clergy, has been a religious house time of out mind, sometimes under the denomination of a priory, sometimes under that of a 'spital or hospital: at its dissolution under 31st Henry VIII. it was called Elsyn's 'Spital, from the name of its founder, a mercer, in 1329. At present it is a composition of both, viz. a college for the

clergy of London, who were incorporated in 1630, in pursuance of the will of Dr. White, under the name of the President and Fellows of Sion College; and an hospital for ten poor men and as many women. The officers of the corporations are the president, two deans, and four assistants; who are annually chosen from among the rectors and vicars of London and are subject to the visitation of the bishop. They have a good library built and stocked by Mr. Simpson, and furnished by several other benefactors, chiefly for the clergy of the city, without excluding other students on certain terms; and a hall, with chambers for students, generally occupied by the ministers of the neighbouring parishes.

COLLEGE, ROYAL NAVAL, at Portsmouth. See ACADEMY.

COLLEGE, ROYAL MILITARY, at Farnham and at Marlow. See ACADEMY.

COLLEGE, EAST INDIA, at Hertford. See HERTFORD.

COLLEGE, EAST INDIA, at Fort William, Calcutta, was a favorite project of the Marquis Wellesley's. It was first announced by an official minute of the governor, relative to the college of Fort William, dated the 18th August, 1800. *Asiatic Register*, 1800.

In this project he is supposed to have contemplated a magnificent repository of European principles and Asiatic erudition, in which the stores of written learning and recorded wisdom might indefinitely accumulate, and in which the sages of the east might find studious solitudes still more deeply attractive than the sacred shades of Benares. 'There certainly is no reason to question the truth of this notion,' says an able critic of this minute. 'Nothing is more credible than that such prospects as these might fill up the distance of the picture which lord Wellesley had framed to himself; but the utmost injustice would be done to the views of that enlightened statesman, if it were not distinctly admitted that his great object was one of a nature more pressing, more practical, and more closely congenial with that solicitude for the rights and happiness of the people, which, after all, constitutes the true sublime of legislation and government. Throughout his minute, the actual deficiencies of the civil service, and the means of supplying those deficiencies, form the grand and the solitary theme of discussion. He has no time to speak or to think of any thing else; and his reasoning must have been sadly thrown away on those, whom it has not convinced that this subject alone might worthily exercise the united reflection and eloquence of India and of England.'

With regard to the actual state of the qualification of the civil servants before the existence of the Calcutta college, the declarations of lord Wellesley were perfectly frank and explicit. Compared with the vast disadvantages under which the service had labored, he admits that those qualifications were great and even wonderful; compared with the exigencies of the state, with the number of the servants, and with the magnitude and arduous nature of the trusts confided to them, he pronounces them decidedly inadequate.

Inced by these considerations, lord Wellesley proceeded to establish, by public regulation, the college of Fort William. It was placed under the immediate government of a provost and a vice-provost. Professorships were instituted in a great variety of departments. An attendance on the college for three years was made compulsory on all persons appointed to the civil service of Bengal but the junior servants at the other presidencies were also to be admissible. Degrees were instituted as indispensable qualifications for certain offices in the service. The branches of knowledge for which provision was to be made were, the Oriental languages, nine in number; the Mahommedan and Hindoo systems of law; the principles of ethics, jurisprudence, and the law of nations; the English law; the regulations and laws of British India; the modern languages of Europe; classical literature; general history; the history of Hindostan; political economy, geography, mathematics, astronomy, natural history, botany, and chemistry. But this great project did not meet with the cordial concurrence of the directors of the East India Company at home. The college of Fort William was in the first instance suspended, but was afterwards continued on a reduced scale, which confined it to a seminary for the instruction of the Bengal civil servants in the Oriental languages appropriate to that presidency. At a subsequent period, a similar establishment, but proportionably smaller, was framed at Madras.

COLLEGE is a designation which certain respectable Dissenting bodies have given, of late, to some of their superior academical foundations. We can only notice here

CHESHUNT COLLEGE, an institution in the connexion, and originally under the patronage, of the countess of Huntingdon, who first founded and supported, at her own sole expense, an institution of this kind in Wales, for the instruction and introduction of young men designed for the ministry. This building, which was situate at Talgarth in the county of Brecon, was publicly opened, and a sermon preached on the occasion, by the Rev. George Whitfield, on the 24th of August, in the year 1768; and from it her ladyship had the satisfaction of seeing many eminent ministers go forth to teach and preach Jesus Christ.

In the year 1787 several of her friends, knowing that the aid afforded by lady Huntingdon must cease with her life (her ladyship's income being only a jointure), offered themselves to form a Society for the continuance and support of her college, when it should be deprived of her fostering care. This proposition being highly approved by lady H., she was pleased to appoint ten persons to act as Trustees of the Institution, whenever her decease should call such a trust into exercise; to whom she also bequeathed all her own property therein.

On lady Huntingdon's death, which happened on the 17th of June, 1791, the Trustees called together the friends of the Institution in London, and it was determined to remove the college from Wales, and to provide a suitable house and premises in the neighbourhood of the metropolis: shortly after, the freehold of the premises now

occupied, situate at Cheshunt, in Hertfordshire, about fourteen miles from London, was purchased; consisting of a family house, with offices, a large garden and orchard, bounded by the new river, with a field adjoining; comprising in the whole upwards of nine acres. This house was publicly opened for the new college on the 24th of August, 1792; a neat chapel has subsequently been erected on the premises.

COLLEGE, Highbury, is a designation which has this year, 1826, been given to the institution, formerly called the Hoxton Academy see our article **ACADEMY** on its removal to Islington. Its principles and general management remain, we believe, the same; but new and handsome accommodations are afforded; the students have received a new stimulus, and the whole institution a new organisation.

COLLEGE, Strampore, is a learned institution among the Baptist missionaries of that place, at present in its infancy; but owing its foundation entirely to the noble views and designs of Messrs Carey, Marshman, and their associates in the East, who have already raised a magnificent sum of money for its establishment, and propose, by offering a superior education to the respectable classes of the natives of India, to interest that continent more effectually in their other benevolent and Christian enterprises.

COLLEGE, MAYNOOTH. The royal college of St. Patrick was instituted by an act of the Irish parliament, in 1795, for the education of the Irish Roman Catholic clergy. Here is also a lay college, established by private subscription in 1802. The town of Maynooth is in the county of Kildare, twelve miles west by north of Dublin.

For the colleges of North America, see our article **AMERICA, NORTH**.

COLLEGIAL, *adj.* from college. Relating to a college; possessed by a college.

COLLEGIAN, *n. s.* from college. An inhabitant of a college; a member of a college.

COLLEGIANS, COLLEGIANS, or COLLEGIATES, a religious sect, formed among the Armenians and anabaptists in Holland, about the beginning of the seventeenth century; so called because of their colleges, or meetings, twice every week; where every man has the same liberty of expounding the scripture, praying, &c. They are said to be all either Arians or Socinians; they never communicate in the college, but meet twice a-year from all parts of Holland at Rhinsbergh, whence they are also called Rhinsberghers, where they communicate together; admitting every one that presents himself, professing his faith in the divinity of the holy scriptures, and resolution to live suitably to their precepts and doctrines, without regard to his sect or opinion. They have no particular ministers, but each officiates as he is disposed.

COLLEGIATE, *adj.* Low Lat. *collegiatus*. Containing a college; instituted after the manner of a college.

I wish that yourselves did well consider how opposite certain of your positions are unto the state of *collegiate* societies, whereon the two universities consist.

H.oker, Preface.

A collegiate church was such as was built at a convenient distance from a cathedral church,

wherein a number of presbyters were settled, and lived together in one congregation.

COLLEGIATE, *n. s.* from *collego*. A member of a college; a man bred in a college; an university man.

These are a kind of empirics in poetry, who have got a receipt to please; and no *collegiate* like them, for purging the passions. *Rymer.*

COLLEGIATE CHURCHES have no bishop's see, yet have the ancient retinue of the bishop, the canons and prebends. Such are Westminster, Rippon, Windsor, &c. governed by deans and chapters. Of these there are two kinds, some of royal, and others of ecclesiastical foundation; each of them, in matters of divine service, regulated in the same manner as the cathedrals. There are even some collegiate churches that have the episcopal rights. Some of these were anciently abbeys, which in time were secularised. The church of St. Peter's, Westminster, was anciently a cathedral; but the revenues of the monastery being, by the act of 1st Eliz. vested in the dean and chapter, it commenced a collegiate church. In several causes, the styling it cathedral, instead of collegiate church at Westminster, has occasioned error in the pleadings.

COLLET, *n. s.* Fr. from Lat. *collum*, the neck. Anciently something that went about the neck; sometimes the neck. That part of a ring in which the stone is set. A term used by turners.

COLLET, in glass-making, is that part of glass vessels which sticks to the iron instrument wherewith the metal was taken out of the melting-pot: these are afterwards used for making green glass.

COLLIDE, *v. a.* Lat. *collido*. To strike against each other; to beat, to dash, to knock together.

Scintillations are not the ascension of air upon collision, but inflammable effluences from the bodies *collided*. *Broune.*

COLLIER, *n. s.* From coal. A digger of coals, who works in the coal-pits; a coal merchant; a ship employed exclusively in the coal trade. Colliery is the place where coals are either dug or sold. It is sometimes applied to the trade itself.

I knew a nobleman a great grasier, a great timberman, a great *collier*, and a great landman. *Bacon.*

COLLIER is a vessel employed to carry coals from one port to another; chiefly from the north of England to the capital, and more southerly parts, though they are also sent to foreign markets.

COLLIER (Jeremy), a learned English non-jurant divine, born in 1650, and educated at Caius College, Cambridge. He came to London in 1685, where he was made lecturer of Gray's Inn; but the change of government that followed, soon rendered the public exercise of his function impracticable. He was committed to Newgate for writing against the revolution, and for carrying on a treasonable correspondence, but was released both times, without trial, by the intervention of friends. He carried his scruples so far, as to prefer confinement to the tacit acknowledgment of the jurisdiction of the court, by accepting his liberty upon bail. Agreeably

to these principles, he acted a very extraordinary part, with two other clergymen, at the execution of Sir John Friend and Sir William Perkins, by giving them solemn absolution, and by imposition of hands; absconding for which, he continued in outlawry to his death in 1726. These proceedings having put a stop to his activity, he employed his retired hours rather more usefully in literary works. In 1698 he attempted to reform our theatrical entertainments, by publishing his *Short View of the Immorality and Profaneness of the English Stage*, which engaged him in a controversy with the wits of the time; but as Mr. Collier defended his censures not only with wit, but with learning and reason, it is allowed that the decorum observed, for some time, by succeeding dramatic writers, was greatly to be attributed to his animadversions. He next undertook a translation of Moreri's *Historical and Geographical Dictionary*, a work of extraordinary labor, and which appeared in four vols. folio. After this, he published *An Ecclesiastical History of Great Britain*, chiefly of England, in two vols. folio, which is allowed to be written with great judgment and impartiality. He was besides engaged in several controversies, to which his conduct and writings gave rise. In queen Anne's reign he had offers of considerable preferment, upon submission; but, being a nonjuror upon principle, he refused to listen to any terms. He died in 1726.

COLLIFLOWER, *n. s.* *Flos brassica*; from Sax. *caþl*, cabbage and flower; properly cauliflour. A species of cabbage. See **BRASSICA**.

COLLIGATION, *n. s.* Lat. *colligatio*. A binding together.

These the midwife contrived into a knot, whence that tortuosity or nodosity in the navel, occasioned by the colligation of vessels. *Brouene's Vulgar Errours*.

COLLIMATION, *n. s.* Lat. *collimo*. The act of aiming at a mark; aim.

COLLIMATOR, **FLOATING**, in astronomy, an instrument invented by captain H. Kater, to supply the place of a level, or plumb-line, in astronomical observations, and to furnish a ready and perfectly exact method of determining the position of the horizontal or zenith point on the limb of a circle or zenith sector. Its principle is the invariability, with respect to the horizon of the position, assumed by any body of invariable figure and weight floating on a fluid. It consists of a rectangular box containing mercury, on which is floated a mass of cast-iron about twelve inches long, four broad, and half an inch thick, having two short uprights or Y's of equal height, cast in one piece with the rest. On these is firmly attached a small telescope, furnished with cross wires, or, what is better, crossed portions of the fine balance-spring of a watch, set flat-ways, and adjusted very exactly in the sidereal focus of its object glass. The float is browned with nitric acid to prevent the adhesion of the mercury, and is prevented from moving laterally by two smoothly polished iron pins, projecting from its sides in the middle of its length, which play freely in vertical grooves of polished iron in the sides of the box. When this instrument is used, it is placed at a short distance from the circle whose horizontal point is to be ascertained, on either

side, suppose the north, of its centre, and the telescopes of the circle and of the collimator are so adjusted as to look mutually at each other's cross wires, in the manner lately practised by Messrs. Gauss and Bessel, first of all coarsely, by trial, applying the eye to the eye-glasses of the two instruments alternately; and, finally, by illuminating the cross wires of the collimator by a lantern and oiled paper, taking care to exclude false light by a black screen. Having an aperture equal to that of the collimator, and making the coincidence in the manner of an astronomical observation, by the fine motion of the circle. The microscopes on the limb are then read off, and thus the apparent zenith distance of the collimating point, intersection of the wires, is found. The collimator is then transferred to the other (south) side of the circle, and a corresponding observation made without reversing the circle, but merely by the motion of the telescope on the limb. The difference of the two zenith distances so read off is double the error of the zenith or horizontal point of the graduation, and their semi-sum is the true zenith distance of the collimating point, or the co-inclination of the axis of the collimating telescope to the horizon.

By the experiments detailed in captain Kater's paper, read before the Royal Society, January, 1825, it appears that the error to be feared in the determination of the horizontal point by this instrument, can rarely amount to half a second, if a mean of four or five observations be taken. In 151 single trials, two only gave an error of two seconds, and one of these was made with a wooden float.

COLLIN D'HARLEVILLE (John Francis), a French dramatist and advocate. He commenced his dramatic career in 1786, with the comedy of the *Inconstant*. This was followed by some others, previous to the appearance of *Le Vieux Celibataire*, which is considered as his chef d'œuvre. He afterwards produced a great variety of inferior dramas, and was the author of a poem entitled, *Melpomène et Thalia*, 1799, 8vo.; and of many pieces inserted in the *Almanac of the Muses*. He died at Paris in 1806, aged fifty. A collective edition of his works appeared in four vols. 8vo., 1805.

COLLINA, a gate of Rome, at the Collis Quirinalis, near the temple of Venus Erycina; called also *Salaria*, because the Sabines carried their salt through it, and now *Sabara*.

COLLINEATION, *n. s.* Lat. *collinco*. The act of aiming.

COLLINGTON, a parish of Scotland, in the county of Mid-Lothian, which approaches within two miles of Edinburgh. It extends about four miles east and west, and about five in a south and north direction, and takes in part of the Pentland Ridge, and Logan House Hill, the highest point being in this parish. This hill is found, by repeated barometrical observations, to be 1700 feet above the level of the sea at Leith. The arable lands slope gently from the skirts of the hills to the level of the river, and are enclosed and highly cultivated. The river Collington, or rather the Water of Leith, abounds with much romantic scenery; and in a course of ten miles, drives no fewer than seventy-one mills.

COLLINGWOOD (Cuthbert), baron, was born at Newcastle-upon-Tyne, 1748, and educated at the same school with lord chancellor Eldon. He entered the navy in 1761, and in the action of June the 1st, 1794, was flag-captain on board the *Prince*, admiral Bowyer. He commanded the *Excellent*, in 1797, during the battle off Cape St. Vincent. In 1799 was rear-admiral of the white, and promoted to the red in 1801. In 1804 he assisted in the blockade of Brest; but his most remarkable service was in the great victory of Trafalgar, in which his fine manner of bringing his ship into action, and the skill and bravery with which he fought her, excited the admiration of Nelson, upon whose fall, the command of the fleet devolved upon him. For his excellent conduct on this and other occasions, he was continued in the command of the fleet, and elevated to a barony. He died on board the *Ville de Paris*, while cruising off Minorca, the 7th of March, 1810, and was honored with a public funeral at St. Paul's.

COLLINS (Arthur), a famous genealogist, was born at Exeter in 1682. The first edition of his *Peerage* was published in 1703, and a second in 1715, four vols. folio. The latest edition was that of 1812, published under the care of Sir Egerton Brydges. He also wrote a *Baronetage*, which was first published in 1720, in two volumes, and subsequently, in 1741, in five volumes. His other works are: 1. *The Life of Cecil, lord Burleigh*, 1732. 8vo.; 2. *The Life of Edward the Black Prince*, 1740, 8vo.; 3. *Letters and Memorials of State*, collected by Sir Henry Sidney and others, 1746, two vols. folio; 4. *Historical Collections of the Noble Families of Cavendish, Holles, Vere, Harley, and Oglo*, 1752, folio. The private life of Collins is little known: except that George II. granted him a pension of £200 per annum, a short time before the year 1760, in which he died.

COLLINS (Anthony), a deistical writer, born at Heston, near Hounslow, in Middlesex, in 1676, was the son of Henry Collins, a gentleman of about £1500 a-year. He was first bred at Eton College, and then went to King's College, Cambridge. He was author of several curious books. His first remarkable piece was published in 1707, *An Essay concerning the Use of Reason in Propositions, the Evidence whereof depends on Human Testimony*. In 1702 he entered into the controversy between Mr. Clark and Dr. Dodwell, concerning the immortality of the soul. In 1713 he published his *Discourse on Free-Thinking*. In 1715 he retired into the county of Essex, where he acted as a justice of peace, and published a *Philosophical Essay concerning Human Liberty*. In 1718 he was chosen treasurer of the county, an office he discharged with great honor. In 1724 he published his *Historical and Critical Essay on the Thirty-Nine Articles*. Soon after, he published his *Discourse of the Grounds and Reasons of the Christian Religion*; to which is prefixed, *An Apology for Free Debate and Liberty of Writing*; which piece was immediately attacked by a great number of writings. In 1726 appeared his *Scheme of Literary Prophecy Considered, in a View of the Controversy occasioned by a late book, en-*

titled, A Discourse of the Grounds, &c. This was replied to by several writers, particularly by Dr. John Rogers, in his *Necessity of Divine Revelation asserted*; in answer to which, Collins wrote *A Letter to the Rev. Dr. Rogers, on Occasion, &c.* His health began to decline some years before his death, and he was very much afflicted with the stone, which at last put an end to his life at his house in Harley-square, in 1792. His curious library was open to all men of letters, to whom he readily communicated all the assistance in his power; he even furnished his antagonists with books to confute himself, and directed them how to give their arguments all the force of which they were capable.

COLLINS (John), F. R. S. an eminent accountant and mathematician, born in 1624, and bred a bookseller, at Oxford. Besides several treatises on practical subjects, he communicated some curious papers to the Royal Society, which are to be found in the early numbers of the *Philosophical Transactions*; and was the chief promoter of many other scientific publications in his time. He died in 1683; and about twenty-five years after, all his papers coming into the hands of the learned William Jones, Esq. F. R. S. it appeared that Mr. Collins had held a constant correspondence for many years with all the eminent mathematicians; and that many of the late discoveries in physical knowledge, if not actually made by him, were at least brought forth by his endeavours.

COLLINS (William), an admirable poet, born at Chichester, about A. D. 1724. He received his classical education at Winchester: after which he studied at Oxford, where he applied himself to poetry, and published his *Oriental Eclogues*. He was naturally possessed of an ear for all the varieties of harmony and modulation; and was, at once, capable of soothing the ear with the melody of his numbers, of influencing the passions by the force of pathos, and of gratifying the fancy by the luxury of his descriptions. With these powers he came to London, and first attempted lyric poetry. In 1746 he published his *Odes, Descriptive and Allegorical*: but the sale of this work not being answerable to its merit, he burnt the remaining copies in indignation. Being a man of liberal spirit and small fortune, his pecuniary resources were soon exhausted, and his life became a miserable succession of necessity, indolence, and dissipation. He projected books which he was not able to execute; and became in idea an historian, a critic, and a dramatic poet, but wanted the means to carry these ideas into execution. Obligated to subsist by the repeated contributions of a friend, or the generosity of a casual acquaintance, his spirits became oppressed, and he sunk into a sullen despondence. While in this gloomy state of mind, his uncle, colonel Martin, died, and left him a considerable fortune. But this came too late for enjoyment; he had been so long harassed by anxiety and distress, that he fell into a nervous disorder, which, at length, reduced the finest understanding to the most deplorable childishness. In the first stages of this disorder, he endeavoured to relieve himself by travelling, and passed into France: but the growing malady

obliged him to return; and having continued, with short intervals, in this pitiable state till 1756, he died in the arms of his sister. The ingenious Mr. Langhorne published his poetical works, with memoirs of the author, in one volume, 12mo.

COLLINSON (Peter), F. R. S., an eminent naturalist and antiquarian, descended of an ancient family, was born on the paternal estate called Hugal-hall, near Windermere-lake, in Westmoreland. Whilst a youth he began to make a collection of dried specimens of plants, and had access to the best gardens round London. He became early acquainted with the most eminent naturalists of his time; Drs. Derham, Woodward, Dale, Lloyd, and Sloane, were amongst his intimate friends. Collinson was elected a fellow of the Royal Society, December 12th, 1728, and perhaps was one of its most useful members, not only in supplying them with many curious observations himself, but in promoting a most extensive correspondence with learned and ingenious foreigners in all countries, and on every useful object. He communicated to the learned in distant parts of the globe the discoveries and improvements in natural history in this country, and received similar information from the most eminent persons in almost every other. His correspondence with the ingenious Cadwallader Colden, esq. of New York, and the justly celebrated Dr. Franklin, of Philadelphia, furnish instances of the benefit resulting from his attention to improvements. The latter communicated his first essays on electricity to Mr. Collinson in a series of letters which were then published, and have been reprinted. The account procured of the management of sheep in Spain, published in the Gentleman's Magazine for May and June, 1764, may not be considered among the least of the benefits accruing from his extensive correspondence. He was the first who introduced the great variety of seeds and shrubs which are now the principal ornaments of every garden; and it was owing to his indefatigable industry, that so many persons of the first distinction are now enabled to behold groves, transplanted from the western continent, flourishing as luxuriantly in their several domains as if they were indigenous to Britain. He had correspondents in almost every nation in Europe, some in Asia, and even at Pekin; who transmitted to him the most valuable seeds they could collect, in return for the treasures of America. The great Linnæus, during his residence in England contracted an intimate friendship with Mr. Collinson. Besides his attachment to natural history, he was very conversant in the antiquities of Britain, having been elected a member of the Society of Antiquaries, April 7th, 1737; and he often supplied them with curious articles. He died in 1768.

COLINSONIA, in botany, a genus of the monogynia order and decandria class of plants: natural order fortieth, personatæ: cor. unequal, under lip multifold, and the segments capillary: SEED, one and perfect. There two species, natives of North America.

COLLIQUAMENTUM, in natural history, an extremely transparent fluid in an egg, observable after two or three days incubation, containing the first rudiments of the chick. It is in-

cluded in one of its own proper membranes; distinct from the albumen. Harvey calls it the oculus.

COLLIQUATE, *v. a. & v. n.* } Lat. *colli-*
COLLIQUABLE, *adj.* } *quico, colliqua-*
COLLIQUAMENT, *n. s.* } *tio, collique-*
COLLIQUANT, *adj.* } *facio.* Tomelt,
COLLIQUATION, *n. s.* } to dissolve, to
COLLIQUATIVE, *adj.* } turn from solid
COLLIQUAFATION, *n. s.* } to fluid. This
 is the only sense, and therefore every derivative, is
 as simple in its application as its etymon.

After the incorporation of metals by simple *colliquesfaction*, for the better discovering of the nature and consents and dissents of metals, it would be tried by incorporating of their dissolutions.

Bacon's Physical Remains.

From them proceed rarefaction, *colliquation*, concoction, maturation, and most effects of nature.

Id. Natural History.

Ice will dissolve in fire, and *colliquate* in water or warm oils.

Browne's Vulgar Errors.

Glass may be made by the bare *colliquation* of the salt and earth remaining in the ashes of a burnt plant.

Boyle.

The fire melted the glass, that made a great show, after what was *colliqueted* had been removed from the fire.

Id.

A *colliquative* fever is such as is attended with a diarrhœa, or sweats, from too lax a texture of the fluids.

Quincy.

It is a consequent of a burning *colliquative* fever, whereby the humours, fat, and flesh of the body are melted.

Harvey.

Any kind of universal diminution and *colliquation* of the body.

Id. on Consumptions.

The tender consistence renders it the more *colliquable* and consumptive.

Id.

The fat of the kidneys is apt to be *colliquated* through a great heat from within, and an ardent *colliquative* fever.

Id.

COLLIQUATION, in chemistry is applied to animal, vegetable, and mineral substances, tending towards fusion. See **FUSION**.

COLLIQUATION, in physic, is applied to the solid parts, when they waste away, by the animal fluids being exhausted through the several glands, and particularly those of the skin, which occasion fluxes of many kinds, but mostly profuse and clammy sweats.

COLLISION, *n. s.* Lat. *collisio*. The act of striking two bodies together; the state of being struck together; a clash.

Or, by *collision* of two bodies grind

The air attrite to fire. *Milton's Paradise Lost.*

The flint and the steel you may move apart as long as you please; but it is the hitting and *collision* of them that must make them strike fire. *Bentley.*

Then from the clashes between popes and kings,
 Debate, like sparks from flint's *collision* springs.

Denham.

The devil sometimes borrowed fire from the altar to consume the votaries; and, by the mutual *collision* of well-meant zeal, set even orthodox Christians in a flame.

Decay of Piety.

COLLOCATE, *v. a.* } Lat. *colloco, collo-*
COLLOCATION, *n. s.* } *catio.* To place; to
 station; the act of placing; the disposition of a
 thing; the state of being placed.

If you desire to superinduce any virtue upon a person, take the creature in which that virtue is most

eminent; of that creature take the parts wherein that virtue is *collected*. *Bacon*.

In the circulation of the spirits in bodies, the collection is equal or unequal; and the spirits coalesce or diffused. *H.*

COLLOCUTION, *n. s.* Lat. *collocutio*. Conference; conversation.

To **COLLOGUE**, *v. a.* Probably from Lat. *colloquor*. To wheedle; to flatter; to please with kind words. A low word.

COLLOP, *n. s.* Minshew derives it from coal and op, and says, it is a rasher broiled upon the coals. It is sometimes used for a slice of meat without any reference either to roasting or heating, and sometimes as a term of endearment.

Come, Sir, page.

Look on me with your *collops*, *o' sweet villain*,
Most dearest, my *collop*. *Shakespeare, Winter's Tale.*

Thou art a *collop* of my flesh.

And for thy sake I have shed many a tear.

H. Henry VI.

The lion is upon his dead belly: not an enemy that does not apply for a *collop* of him. *L'Esrange.*

Sweetbread and *collops* were with skewers pricked about the sides. *De Witt's Fables.*

A cook perhaps has mighty things pressed;
Then sent up but two dishes nicely dressed;
What signifies Scotch *collops* to a feast?

King's Comedy.

COLLOQUY, *n. s.* Lat. *colloquium*. Conference; conversation; alternate discourse; talk.

My earthly, by his heavenly overpowered,

In that celestial *colloquy* and time.

As with an object that exalts the sense,

Dazzled, and spent, sunk down.

Milton's Paradise Lost.

In retirement make frequent *colloquies*, or short discourses, betwixt a God and thy own soul.

Taylor.

COLLOT d'Honnors, J. M., a distinguished French revolutionist, was born at Malinvaux, near Chantres. He was, early in life, a strolling actor, in which capacity he visited Lyons; and finally Paris, at the commencement of the public commotions. He was soon noticed as a street orator, and member of the Jacobin club; and in 1792 accused La Fayette of treason at the bar of the National Assembly. The same year he published his *Almanach du Pere Gerard*, in favor of a constitutional monarchy. After this he became the decided enemy of royalty; was one of the members of the municipality on the 10th of August, 1792, who procured the dethronement of Louis XVI.; a member of the Council of Justice, and a deputy of the National Convention. He demanded, at the first sitting, the abolition of royalty, and that death should be the punishment of emigration. As might have been expected, he voted for the execution of the king; and was soon after sent to Orleans and Lyons, where, in the name of liberty, he committed the most horrid butcheries, having assisted in the destruction of the Girondists. He was nominated, with other members of the Jacobin club, to draw up the act of accusation against kings. His life was attempted in May, 1794, by a man named Admiral, who fired two pistols at him. July 18th he was appointed

president of the Convention, and joined with other members to procure the overthrow of Robespierre. On the 28th of August, Lecointre, of Versailles, denounced him and others, as accomplices of the tyrant they had destroyed; and though this accusation was rejected, they were arrested in March, 1795, on fresh charges, and soon after condemned to exile. Collot, endeavouring to excite an insurrection of the negroes, was confined in the fortress of Sinamari, where he died in November, 1796. He wrote several dramatic pieces.

COLLOW, *n. s.* More properly *colly*, from coal.

Colly is the word by which they denote black grime of burnt coals, or wood. *We heard on Fossil.*

COLLUCTANCY, *n. s.* Lat. *collocutio*.

COLLUCTATE, *n. s.* Lat. *collocutio*. Contest; struggle; contrariety; opposition; spite.

The thermæ, natural baths, or hot-springs, do not owe their heat to any combination or effluence of the minerals in them. *Woodward's Nat. History.*

COLLUDE, *v. n.* Lat. *colludo, collusio*.

COLLUSIVE, *n. s.* } To conspire in a fraud;

COLLUSIVE, *adj.* } to act in concert for a

COLLUSIVELY, *adv.* } bad purpose; to play

COLLUSORY, *adj.* } into each others hands.

Collusion is, in our common law, a deceitful agreement or compact between two or more, for the one part to bring an action against the other to some evil purpose; as to defraud a third of his right. *Caroli.*

By the ignorance of the merchants, or dishonesty of weavers, or the collusion of both, the ware was bad, and the price excessive. *Swift.*

COLLUM, the neck. See ANATOMY.

COLLUMPTON, a neat town of Devonshire, seated on the river Columb, near its mouth. It carries on the woollen manufacture. It is ten miles north of Exeter, and 150 west by south of London.

COLLUTHIANS, a religious sect who rose about the beginning of the fourth century, on occasion of the indulgence shown to Arius by Alexander, patriarch of Alexandria. Several people being scandalised at so much condescension, Colluthus, a priest of the same city, hence took a pretence for holding separate assemblies, and by degrees proceeded to the ordination of priests, as if he had been a bishop; pretending a necessity for this to oppose Arius. To his schism he added heresy; teaching that God did not create the wicked, &c. He was condemned by a council held at Alexandria by Osius, A. D. 330.

COLLY, *v. a.* & *n. s.* From coal. To grime with coal; to smut with coal.

Brief as the lightning in the *colly'd* night.

That in a speed, unfolds both heaven and earth

And, ere a man hath power to say, behold,

The jaws of darkness do devour it up. *Shakespeare.*

Suppose thou saw her dressed in some old hirsut attire, out of fashion, coarse raiment, besmeared with soot, *colly*, perfum'd with opopanax.

Burton on Melancholy.

COLLYBUS, *κόλλυβος*, in antiquity, the rate of exchange.

COLLYRE, or **COLLYRIDES**, in antiquity, an ornament of hair, worn by the women on their

necks. It was made in the form of the small roundish cakes called *κολληρααι*, *collyrae*.

COLLYRIDIANs, in church history, a sect towards the close of the fourth century, denominated from a little cake, called by the Greeks *κολληραϊται*, *collyridia*, which they offered to the Virgin Mary. They were chiefly Arabian women, who, out of an extravagant veneration for the Virgin, met once a year to celebrate a solemn feast, and to render divine honors to Mary, as to a goddess; eating the cake which they offered in her name. St. Epiphanius, who relates the history of this superstitious ceremony, ridicules it. They sprung up in opposition to the Antidico-Marianitis.

COLLYRIUM, *n. s.* Lat. An ointment for the eyes.

COLMAN (George), a celebrated theatrical writer, was born at Florence about 1733. His father, Thomas Colman, esq. married a sister of the countess of Bath, being, at that time, British resident at the court of the grand duke of Tuscany. He received the early part of his education at Westminster school, where Churchill, Lloyd, Thornton, and others, who afterwards distinguished themselves in the literary world, were his intimate companions. His poetical genius appeared while at school; and a copy of verses which he addressed to his cousin lord Pulteney, were afterwards published in the Saint James's Magazine. From Westminster he removed to Christ Church College, Oxford, where he gave many proofs of his lively genius; and, in conjunction with Bonnel Thornton, produced a weekly paper called the *Connoisseur*, which was continued from January, 1754, to September, 1756, and published afterwards in 4 vols. 12mo. This work appeared about the same time with the *World*, the *Adventurer*, and the *Rambler*, and though it met not with an equal share of approbation, yet it may justly be affirmed that it contains some papers superior to any in them, for ludicrously portraying the manners of the day. After taking the degree of A. M. Mr. Colman left college, and took up his residence in London. He entered at Lincoln's Inn, and was soon admitted to the bar, but he never followed that profession; being more inclined to the pursuit of literature. In 1760 he published a dramatic piece of great humor, entitled *Polly Honeycombe*, which was acted at Drury-lane with great success; and the next year he produced the comedy of the *Jealous Wife*, which was thought superior to any which had appeared for many years. By the death of lord Bath in 1754, he came to the possession of a handsome fortune, which was considerably augmented by that of general Pulteney in 1767. Still, however, he continued to write for the stage, and, in conjunction with Garrick, produced that excellent comedy called the *Clandestine Marriage*. He also translated the comedies of Terence into blank verse, which added considerably to his fame as a writer. In 1768 he became a patentee of Covent-garden theatre, but soon after sold his share, and made a purchase of the Haymarket theatre from Mr. Samuel Foote, which he supplied either with original pieces or translations, and for which he was at considerable

pains to engage the ablest actors, particularly in comedy. Having translated Horace's *Art of Poetry*, he prefixed an ingenious account of the design of its author, and added to the value of the whole by numerous critical notes. Among a number of small pieces of the humorous kind, the *Genius*, and the *Gentleman*, were both productions of his. In 1789 he had a stroke of the palsy, which greatly impaired his understanding, in consequence of which his son was entrusted with the management of the theatre; and he died in August, 1794.

COLMAN (St.), the founder of the church and bishopric of Cloyne in Ireland, flourished about the end of the sixth century. A well-reputed holy, to the north-west of Cloyne, is dedicated to him, and is much frequented by the Irish Catholics on his anniversary, November 24th.

COLMAR, *n. s.* Fr. A sort of pear.

COLMAR, a large and handsome town of France, capital of the department of Upper Rhine and ci-devant province of Alsace. It is situated on two small rivers, the Fecht and the Lauch, is surrounded by a wall flanked with towers, and contains 15,000 inhabitants. This town is supposed to be the ancient *Argentivaria*. It was fortified towards the middle of the seventeenth century; but Louis XIV took it in 1673, and demolished the works; and the French have ever since retained it. It is twenty-seven miles north-west of Bale, and thirty-four S. S. W. of Strasburgh.

COLME, a river of France, which branches from the Aa, at Watte, in the department of the Straits of Calais.

COLN, a river of Essex, which rises near Clare in Suffolk, and, passing by Halstead and Colchester, runs into the German Ocean between Mersey Island and the main land. The famous Colchester oysters are bred in the salt water pools, at the mouth of this river.

COLNBROOK, a town of Buckinghamshire, seated on the river Coln, which separates this county from Middlesex. It is a great thoroughfare on the western road, and has several good inns.

COLOCYNTHIS. See *CUCUMIS*.

COLOGNA, a rich town in the Venetian territory, containing 6200 inhabitants, who trade in wine and silk. It lies twenty miles S. S. E. from Vicenza.

COLOGNE, an electorate of Germany, and formerly an archbishopric, but of late years secularised, and included in the grand duchy of the Lower Rhine, under the Prussian dominion. It is mostly situated on the left bank of the Rhine, which bounds it on the east, and separates it from the duchy of Berg; on the north it is bounded by Gueldres and Cleves, on the west by the duchy of Juliers, and on the south by the electorate of Treves. It is about ninety miles long, by about fourteen of average breadth, and contains a population of nearly 220,000 souls. The upper part of this country is covered with large forests; but in the lower, corn and flax are produced in great plenty. It is included between 50° 30' and 51° 25' N. lat., and 6° 35' and 7° 10' E. long., extending in a direction from south-east to north-west something in the

form of a semicircle. The Rhine, which is the principal river, is here a very considerable stream, receiving an accession of the waters of the Nethe, the Aar, the Erp, and the Neufs. The places of chief note are Cologne, the capital, Bonn, a very considerable town, once the metropolis and the residence of the elector, Berghem, Bruyl, and Rheinburg. Great quantities of wine are sent out of this country by means of the Rhine, which flows nearly seventy miles along its borders. There are also some lead and iron mines. The religion most prevalent is the Roman Catholic; but free toleration is enjoyed by the Protestants, who are also eligible to fill public offices. Formerly the dignity of archbishop and that of elector were vested in the same person, who was arch-chancellor of the empire, and occupied the third place in the college.

COLOGNE, the capital of this electorate, is an ancient town, known to the Romans by the name of Colonia Agrippinæ because it was built by Agrippina, the wife of Claudius, and Colonia Ubiorum, from the Ubii, its ancient inhabitants. So early as the year 755 it was an archbishopric, and in 1260 it entered into the Hanseatic league, and was once considered one of the four principal Hanstowns. It is built in the form of a crescent, close to the Rhine, and is fortified with strong walls, flanked with thirty large towers, and surrounded with three ditches, the whole forming a circuit of nearly seven English miles; but it was taken by the French under general Jourdan, on the 6th of October, 1794, not only without resistance, but even with demonstrations of joy. The entrances to the town are by twenty-four gates, and within the walls there are nineteen parishes, two collegiate churches, two abbeys, thirty-nine monasteries, two establishments for noble ladies, an archiepiscopal seminary, and forty-nine chapels, besides some commandaries of the Teutonic order, and of the order of Malta. The French suppressed the university, which was established by pope Urban VI. in 1388, and established in its place a central school, with a library, a museum, philosophical apparatus, and botanic garden. The streets are generally narrow and crooked, and the houses very ill built, the only square worth noticing is the Forum Novum, and the best buildings are the churches. The cathedral is vast but unfinished, in the Gothic style; it was built about the year 1248. Here they say three kings, or wise men, who came from the east to visit the Saviour are interred; they lay in a large purple shrine, spangled with gold, upon a pedestal of brass, in the middle of a square mausoleum, covered within and without with marble and jasper. Formerly it was opened every morning at nine o'clock, when the kings were seen lying at full length, with crowns of gold on their heads, garnished with precious stones. Their names, which are Gaspar, Melchion, and Balthasar, are in purple characters on a little grate, which is adorned with an infinite number of large rich pearls and precious stones,

particularly an oriental topaz, as big as a pigeon's egg, and valued at 30,000 crowns. Over against them are six large branches of silver, with wax candles which burnt night and day. The bones of these men, we are told, were brought to Constantinople by Helena, mother of Constantine, from thence to Milan by Eustorpius, bishop of that see, and afterwards hither by archbishop Rainold. In the Jesuits' college are the portraits of the first thirteen generals of that order, with Ignatius Loyola at their head; and in the church, which is the finest in Cologne, are many rich statues, with an amazing quantity of fine silver plate; and the utensils for mass are all of gold enriched with precious stones. In the Cordeliers' church, is the tomb of our famous countryman, Duns Scotus, surnamed Doctor Subtilis, with this epitaph, 'Scotia me genuit, Anglia me suscepit, Gallia me docuit, Colonia me tenet.' In the church of St. Ursula they pretend to show her tomb, and the bones of the 11,000 virgin martyrs, though this arises from a mistaken inscription; the heads of some of them are kept in cases of silver, some of them covered with stuff of gold and velvet. The canonesses of St. Ursula were all countesses, and had a large revenue. They have, as they say, three of the thorns of our Saviour's crown, and one of the vessels which contained the water that he converted into wine at the marriage of Cana. The church of St. Gestian has a subterraneous church under it. The clergy are very numerous, and had formerly very large revenues; there are said to be not fewer than 2000 ecclesiastics of all ranks. Baron Pointiz said, that though Cologne was one of the greatest cities, it was one of the most melancholy in Europe; there being nothing to be seen but priests, friars, and students, many of whom begged alms with a song; and nothing to be heard but the ringing of bells. The population of this city is estimated at 50,000, the greater part of whom are papists; the Protestants were formerly obliged to repair to the neighbouring town of Mulheim, in the duchy of Berg, for public worship, but they now enjoy toleration in this respect, and have many privileges. The trade of the town is chiefly in their hands.

The principal exports are wine, timber, earthenware, slates and several other minerals, fire-arms, and various articles of hardware and kitchen utensils. Linen, woollen, and silk stuffs, lace, and thread, are manufactured here; and great quantities of eau de Cologne, so famous throughout Europe. It was formerly governed by its own senate in civil matters; but criminal causes belonged to the jurisdiction of the elector and his chapter, of whom the inhabitants were very jealous, so that they would not permit him to reside in the city; his usual residence used, therefore, to be at Bonn. Cologne is seventeen miles east of Juliers, forty-seven from Maestricht, and ten north of Bonn. It is situated in 6° 55' E. long. and 50° 55' N. lat.

COLOMBIA.

COLOMB A, an extensive country, occupying the greater portion of the north and north-western parts of South America, between the parallels of $5^{\circ} 50'$ S. and $12^{\circ} 30'$ N. lat., and 58° and 81° E. long. On the north and north-east it is bounded by the Caribbean Sea and the Atlantic Ocean, on the west by the river Essequibo, which divides it from Guiana, on the south by Brasil eastward, and by Peru westward, while its western coast is washed by the great Pacific Ocean for about twelve degrees of latitude from the south to the north, where it is connected by the isthmus of Darien with the province of Guatimala in North America. In our article AMERICA we have treated, at some length, of this interesting portion of the transatlantic world; but, as its rising prosperity and political importance as an independent state are every day becoming more apparent, we cannot forbear adding a little to our former remarks.

Of this vast country, the eastern part was formerly distinguished by the name of Venezuela or Caraccas, and the western was called New Granada, or Condinamarca, the name of the south-western portion being Quito; the two former of these now constitute the great divisions of the republic of Colombia. For the minor divisions of these great districts, and the population of each, we cannot do better than refer the reader to the Tables given in the description of the country of Colombia, under the article AMERICA.

The most prominent feature on the western side is the great Cordillera of the Andes, which runs through the whole extent from north to south, at an average distance of 150 miles from the Pacific Ocean. Northward, about the second degree of latitude, a branch of this immense ridge strikes off in an east and north-east direction, and soon after another diverges a little to the west, and then due north; forming three different main chains, with many subordinate ones, crossing the country in all directions, while the intervening valleys are watered by the mighty rivers and smaller streams, that rise among the mountains. It is in this region that the Andes reach their greatest elevation, and the stupendous Chimborazo lifts its lofty summit to the height of 7147 yards above the level of the sea, exceeded alone by the vast Himalayan chain in the eastern continent. This mountain towers above all the rest: but to the north and south and east, others of a height little inferior are seen ascending to the skies, and exhibiting, with their snow-clad cones, a striking and beautiful contrast with the dark blue firmament above. The chief of these are Antisana, Cotopaxi, Illinissa, and Pichinga, varying in elevation about 1000 feet from each other. North of the equator this mighty chain diminishes gradually in height, and diverges in the third degree of latitude from the river Atrato, forming a narrow ridge at about 100 miles average distance from the coast, reaching to cape Vela; the greatest eleva-

tion of this branch is about 16,000 feet, the plain of Caraccas in which it stands being 2660 feet above the sea. The Caraccas coast, which is of an immense extent, affords a continuation of this great table land, furnishing the most tremendous precipices in the world, and is lost in the sea nearly opposite to the island of Trinidad. The Cordillera of Caraccas, sometimes, in the western part, exceeds 8,000 feet; it includes some large and beautiful valleys. What is called the Cordillera of the Cataracts of Orinoco forms the second great branch of the Andes; between the third and sixth degrees of north latitude it extends itself, forming the lofty plain of Tuquillo and St. Martin, and exhibiting the peaks of Umama and Cavanami. Here the rivers Guavari, Meta, Zama, and Ymerida, take their rise, and the awful cataracts of Aturé and Maypuré occur. Beyond these this chain is of greater height, and stretches in a southerly direction as far as the Portuguese frontiers, where a vast and impenetrable region of forest extends, over which no European has yet passed. Here are the sources of the magnificent river Orinoco, unknown both to the Spaniards and the civilised Indians themselves. The highest point of this Cordillera is Duida, a volcanic mountain above 8,465 feet high. Three vast plains run between the bases of these branches of the Andes, open to the Atlantic Ocean; the most northerly being that of Orinoco, luxuriant in herbage, but with comparatively few trees, and these widely scattered. Here an immense flat occurs, with vast savannahs, called Los Llanos (the Plains), where the residents of the towns and villages feed innumerable herds of cattle.

The enterprising Humboldt, who penetrated farthest and made the most valuable discoveries in this country, speaking of its general aspect, expresses himself thus:

‘When a traveller, newly arrived from Europe, penetrates for the first time into the forests of South America, nature presents herself to him under an unexpected aspect. The objects, that surround him, recall but feebly those pictures which celebrated writers have traced on the banks of the Mississippi, in Florida, and in other temperate regions of the New World. He feels at every step, that he is not on the confines, but in the very centre, of the torrid zone; not in one of the West India islands, but on a vast continent, where everything is gigantic—the mountains, the rivers, and the mass of vegetation. If he feel strongly the beauty of picturesque scenery, he can scarcely define the various emotions which crowd upon his mind; he can scarcely distinguish what most excites his admiration—the deep silence of those solitudes, the individual beauty and contrast of forms, or that vigor and freshness of vegetable life, which characterise the climate of the tropics. It might be said that the earth, overloaded with plants, does not allow them space enough to unfold themselves. The trunks of the trees are every where concealed

under a thick carpet of verdure; and if carefully transplanted the orchidea, the pipers, and the pathos, which a single courbaril, or American fig-tree nourishes, we should cover a vast extent of ground. By this singular assemblage, the forests, as well as the flanks of the rocks and mountains, enlarge the domains of organic nature. The same lianas which creep on the ground, reach the tops of the trees, and pass from one to another at the height of more than 100 feet. We walked for some hours under the shade of these arcades, that scarcely admit a glimpse of the sky, which appeared to me of an indigo blue, so much the deeper, as the green of the equinoctial plants is generally of a stronger tint, with somewhat of a brownish hue. A great fern tree, very different from the polypodium arboreum of the West Indies, rose above masses of scattered rocks. In this place we were struck for the first time with the sight of those nests in the shape of bottles, or small pockets, which are suspended from the branches of the lowest trees, and which attest the admirable industry of the orioles, that mingle their warblings with the hoarse cries of the parrots and the macaws. These last, so well known for their vivid colors, fly only in pairs, while the real parrots wander about in flocks of several hundreds. A man must have lived in those climates, particularly in the hot valleys of the Andes, to conceive how these birds sometimes drown with their voice the noise of the torrents, which rush down from rock to rock.

Caracac seems to form three distinct zones from east to west: first that of the cultivated land along the shore; then the pasturage, or savannahs; and lastly, one of forests, extending beyond the river Orinoco, penetrable only by means of the rivers that intersect them. It may be said, indeed, to exhibit the three most striking varieties of human society; that of the wild hunter in the woods of Orinoco, of the pastoral life in the savannahs, and the agricultural at the foot of the mountains, near the coast. Along the coasts of the Pacific, the Caribbean Sea, and the Atlantic, is a tract of country, reaching to the Cordilleras, the climate of which is hot, and most unhealthy; in parts where it is well watered the soil is luxuriant, but where the periodical rains fail, or the rivers are liable to dry up in their course, it is parched, and sterile. In the province of Coro, for instance, it has sometimes not rained for four years together, and seasons of similar drought, though not to so great a degree, have been experienced in other parts near the coast. In this region most of the rivers are short in their course, inconsiderable in the volume of their waters, and so rapid, and their beds generally so rocky, as to be navigable but a little distance from their mouths. The river Magdalena alone, which descends 700 miles along the valleys of the Andes, is navigable 550 miles above its mouth, as far as the port of Florida. The Cauca, in the valley of Antioquia, and the Atrato, in Choco, are considerable streams, the banks of which are covered with forests that bespeak a soil fertile to excess; but a burning climate renders human life highly precarious; and innumerable insects and poi-

sonous reptiles destroy all its comfort. As you ascend the mountains the climate grows mild, vegetation is uninterrupted through the whole year; wheat, leguminous plants, and all the productions of the temperate zone abound, and are of excellent quality; venomous animals are rare, and man feels the grateful salubrity of the temperature, conducive alike to his labor and enjoyment. This temperature continues to the height of 9000 feet above the level of the sea, where the air is cold and the sky cloudy, and vegetation slow and stunted. When you reach the elevation of 15,700 feet, you find no trace of it remaining except the lichen, which is found nearly 3000 feet higher; all is solitude, uninterrupted by a single living creature, except the equally solitary condor, and the few human beings whom love of enterprise and discovery may lead to tempt the difficulties of so lofty an ascent. The thermometer of Fahrenheit varies from 77° to 115° as you ascend to the height of 4800; and beyond that, to 8000 feet of elevation, from 50° to 77°. Beyond the mountainous districts, stretching eastward and southward, is an immense tract of level plains, from the Andes to the river Amazon, and the mountainous country, near the Orinoco. Vast savannahs are watered by the above river, and the numerous streams, that compose the Meta and the Apuré; the overflowings of which for four months in the year convert the country into a great lake or inland sea, on which the villages or cattle farms appear like so many islets. These plains are extremely rich in agricultural productions, and feed immense herds of cattle. When the rivers retire within their banks, the whole country is covered with the most luxuriant pasturage. The forests on the banks of the rivers abound with the most valuable timber, and dye-woods, and the soil is excellent for the cultivation of sugar, cotton, coffee, cocoa, indigo, and tobacco. Nature teems with animal and vegetable life; wild beasts, venomous reptiles, and insects, prove the torment of man, who vainly imagines all the comforts of existence designed for his sole use and convenience. Though the climate here is hot, it is not so unhealthy as that of the coast; the air is purified and refreshed by the breezes that are constantly passing over this vast grassy ocean, which extends from the Orinoco to the Andes, 300 miles, in almost every direction. Vera Cruz and Cartagena are the only ports in Condamarea or New Granada, that have any connexion with foreign colonies, or intercourse with any part of Europe, except Spain; the nature of its coast and the situation of its population on the Cordilleras, have few attractions for foreigners, and the dangerous gales of wind from the north render the Mexican Gulf, which bounds this country on the north, very little frequented during a part of the year. The Caracac coasts, on the contrary, possess great advantages for foreign intercourse, from their great extent eastward, from the number of their forts, and their safe anchorage at all seasons. The ports of Cumanana, Barcelona, La Guayra, Porto Cabello, Coro, and Maracaibo, present facilities of intercourse so great, that it is extremely difficult to restrain an illicit trade with foreign parts. The

most favorable parts of the country for colonisation are, unquestionably, the four maritime provinces of Orinoco, Caraccas, Zulia, and Magdalena, near the Gulf of Paria: in the first of these provinces the land is extremely fertile, and particularly famous for the culture of the cocoa. The district of Barcelona is not only very fruitful, but it is almost uninhabited. Of all these provinces, however, Caraccas is the most beautiful, and unrivalled for fertility; but a small portion only of its land is uncultivated, and there is hardly a single estate, that is not so shackled, as to involve a purchaser in endless litigations. Besides this, perhaps, emigrants would do well not to visit this province, since they might with great difficulty renounce its celestial climate and its lovely valleys for the, confessedly, greater advantages of other parts of Colombia. In Zulia the province of Merida has most attractions for the foreign settlers; it has a charming climate, and though its territory is mountainous it is fruitful; all the grains and fruits of the temperate zone are produced in abundance on the high lands, while every tropical production, particularly sugar cane and cocoa, is yielded by the warmest valleys below. Maracaibo also, from its immense lake and gulf, possesses great advantages for agriculture and commerce; nearly a hundred rivers discharge themselves into its basin, the banks of which are amazingly fertile; but many of the settlements have been abandoned on account of their unhealthy climate. But Magdalena is the most advantageous for a foreign settlement; its lands are almost unoccupied, and produce in great abundance coffee, cocoa, cotton, sugar, rice, indigo, tobacco, maize, and fruits and vegetables of every kind. There are also extensive pastures for cattle, the soil of which is excellent. The climate is generally healthy, and the settler may find a temperature suited to his constitution, by ascending the mountains to a greater or less elevation. Game and fish are found in great plenty in the woods and in the adjacent seas. Two principal ports, Santa Marta on the west, and Ciudad del Hacha on the east, tend much to forward the commercial business of this province; the latter, especially, affording an excellent market for the produce raised in the country, and for every article of consumption brought from other parts. Savanilla or Saldanilla, in Carthagena, is the natural port of Magdalena, and is destined, no doubt, by its situation, to become the principal mart for the trade of the interior, though it is now closed in favor of Santa Marta, the communication between which and the river Cauca is circuitous and troublesome, whereas Savanilla lies at the very mouth of that river. The principal defect of this port is the extreme shallowness of water above it, so that even flat boats, when loaded, with difficulty can reach Baranquilla, but this might be remedied were the mouth, called Boca Vieja, stopped up, and the great body of the water directed to the other outlet.

In common with all those countries through which the mighty chain of the Andes passes, Colombia is subject to frequent earthquakes.

There are several volcanoes in this part of that chain, particularly Cotoxipi, Pichincha, Sangai, and El Altar, or Altair, the description of which having been so fully given in the article *ANDES*, we forbear to enlarge. Caraccas, as well as Quito, and the central parts, is liable to very sensible shocks of earthquakes. In 1797 dreadful ravages were produced by them in the month of December; on the first of May, 1802, at eleven at night, there was a pretty strong shock, with oscillation, from west to east; on the 20th of the same month, at four in the morning, another was felt in a vertical direction, and the earth did not recover its horizontal level for the space of two minutes; on the 14th of July following, two shocks occurred at forty minutes past two o'clock in the morning, and another at thirty-five minutes past six. The causes and local origin of these earthquakes must exist in the province of Cumana, since they are more violent there than elsewhere.

The seasons of this part of South America are only two, winter and summer; and these are marked not so much by heat and cold as by rain and drought. In Caraccas, during the wet season, it rains for the space of three hours a day, and more commonly in the evening than in the morning. There are, however, some days in which not a drop of rain falls, and others when it rains incessantly, the country generally, plains, mountains, and valleys sharing its blessings and its inconveniences. It is not drizzling rain as in the northern regions; but it descends in torrents, producing more water in a single day than that of Europe does in a week. The total quantity is ten times that of the polar regions. The rivers inundate the country during the greater part of this season, and the lands are covered to an immense depth, only the tops of the tallest trees being visible, and serving for land-marks. This is the case, especially, in the north plain of Orinoco, which extends 450 miles in length and 120 in breadth. M. de Humboldt describes the dry season in Guiana as a horrible time, and gives an excellent picture of the regeneration of nature, especially of vegetation, on the return of the rain. Crocodiles, and other reptiles, seem then to revive, and multitudes of horses, oxen, wild asses, and ferocious animals, rush, panting with eagerness, from the burning desert to quench their thirst in the marshes, plunging into them and drinking with so much avidity, that they become swollen, and often die in a few hours. The effect is different, however, in some parts; along the coast of Cayenne, Surinam, Berbice, Demerara, and Essequibo the air is refreshed by the sea-breezes, the dry season is delightful, while, on the other hand, the rainy season is hotter and more unhealthy. The climate of Condinamarca is very various; the lofty Cordillera of the Andes, and the snows which constantly cover its summit, subject this country, though lying under the equator, to all the cold of the polar regions, while on the lower plains the heat is intense. The elevated spots between the ridges of the mountains are temperate and settled in their climate, and there Europeans chiefly fix their abode. There are many lakes in Colombia, a great

number of which are formed by the rains, and others are the reservoirs of rivers, which flow into them. The former are frequently met with in the low grounds in the neighbourhood of the Orinoco; the greatest of the second description are Maracaibo and Valencia. The lake of Maracaibo has been already referred to in our article AMERICA, under the division of Colombia: it is very deep and navigable for the largest vessels; its waters are always fresh; but violent storms will sometimes force those of the neighbouring gulf into it. There is generally a considerable undulation on it, and when the north wind blows hard the waves rise very high. The shores in the vicinity are unhealthy in consequence of the vapors that arise in the night; but the richness of the soil in the western part has induced some Spaniards to take up their residence there, in order to cultivate cacao and provisions. On the south it is uncultivated, and without inhabitants; the northern side, though hotter, is much more healthy. The Indians build their villages on the margin of the lake, deeming it the most healthy plan; to one of these the Spaniards gave the name of Little Venice, or Venezuela, which was afterwards transferred to the whole province. There are four of these villages remaining, under the superintendance of a monk. There is a mine or vein of mineral pitch on the north-west of Lake Maracaibo, used in graving vessels, which emits, during the hot weather, corruscations from its surface like frequent lightnings: the natives call them St. Anthony's lanterns; they make use of them in steering by during the dark nights of the torrid zone. The lake of Valencia is of much less extent, being only forty miles long and twelve broad; it is situated in a valley, everywhere, except on the west, surrounded by lofty and steep precipices. Its banks are covered with the most luxuriant herbage. The waters of this lake are much subject to evaporation, and, being elevated more than 1300 feet above the level of the ocean, it is thought that they have some subterraneous communication. This gradual retreat of the waters, and some new islands appearing frequently, have given reason to believe that the lake may perhaps become dry. The southern shores are desert, and a gloomy monotony prevails in consequence of their being overshadowed by a ridge of high mountains, while on the north the country is cheerful and richly cultivated. This part of the shore has the appearance of a garden, regularly laid out with borders of cestrums, azedaracs, and other shrubs always blooming, which join together the scattered farms. The houses are surrounded with trees: the ceiba, with its large yellow flowers, entwines its branches with the purple erithryna; the most vivid vegetable colors form a pleasing contrast with the unclouded uniformity of the sky; and in the dry season artificial watering preserves the burning soil in a state of continual verdure and fertility. Here and there vast masses of granite rock break abruptly through the cultivated vegetation of the valley, nourishing on their bare and forked surfaces a few succulent plants that prepare mould for distant ages, and with their withered branches stand like signals on a high cliff. In ancient times this valley was

covered with waters, and there were probably shoals or islets in the midst of it. The lake has many islands on it, not less than fifteen, forming three clusters: the largest of these, Burro, is two miles long, and is inhabited by Mestizoes, who rear a few goats. The fish is abundant, but there are only three sorts, the guavina, the vagra, and the sardina; their flesh, however, is very insipid in flavor. On the southern shore tobacco is raised, and here are some of the finest plantations in the whole province. In Guiana is the lake of Parima or Paranatinpica, an oblong piece of water about 100 miles long by fifty broad; in an island of which there is a rock of glittering mica, said to have been the site of the city of El Dorado, a supposed place, the streets of which were asserted to be paved with gold. This lake gives rise to the large river Rio Blanco, and is described as situated in lat. $3^{\circ} 40' N.$, and long. $67^{\circ} 20' W.$

It is difficult to find a country in the world so abundant in rivers; every valley has them, either of the larger or smaller description, and, if they are not navigable, yet they would copiously supply all the wants of the population, were it even increased a hundred fold. Those streams which take their rise on the northern sides of the mountains in Caraccas, and flow into the sea, are so fenced in by their rocky banks, and favored by the declivity of their channels, that they seldom overflow, and never for any length of time, or with much detriment to the country; but those which rise on the south of the same mountains, running in smoother and shallower beds, frequently mingle their water through a great part of the year, and form an immense sea in the country. Almost all of these flow to augment the waters of the Orinoco, which is not only one of the largest, but the finest of the rivers of the southern peninsula. We have treated of it among the rivers of South America, and shall not therefore repeat our observations. Rising in the lake Ipara, it winds a circuitous course, passing through lake Parima, and afterwards receiving the Guaviare; and more northward the Meta, the Apura, the Arauca, and a multitude of other streams, large and small, it issues by numerous estuaries into the Atlantic opposite to Trinidad. Seven of its mouths are navigable, but very dangerous; the largest is eighteen miles broad. The scenery on the banks of this great river is truly magnificent, forests of aromatic trees diffuse, to a great extent, their delightful odors and agreeable shade; birds of the most beautiful plumage are observed in every direction, and the traveller is astonished at the innumerable monkeys that are seen leaping from tree to tree, with the most surprising agility. Vast plains of the greatest verdure extend from the forests to a distance that no eye can reach. The cataracts of the Orinoco, said to be the most awful in the world, occur near the bend of the river at the villages of Maypures and Atures, in about 6° north latitude. From the end of April to October the waters are swelled by the rains, rising to the height of forty feet above their lowest level; they then begin to subside, and continue sinking till March, when they are at the lowest; they fluctuate in this way with constant regularity.

The rains are not the only causes of this variation; the principal cause, no doubt, is the melting of the snows in the mountains of Bogota. The seas that wash the coasts of Colombia are not remarkable for any great variation in the tides; in some parts on the north and north-east, near the gulf of Paria, they rise during the equinoxes to six or seven feet; but near the mouths of the Orinoco they scarcely attain the height of ten inches. The trade winds prevail off the coasts, blowing from north-east by east; but nearer to the shore they blow only from nine in the morning till evening, and are succeeded in the night by the land breezes. All the coasts of Caraccas are exposed to rolling and monstrous billows, and there is only one port, the road of Porto Cabello, where the navy can ride securely.

The principal place on the north of this vast country is Caraccas; its port, La Guayra, is situated in lat. $10^{\circ} 36'$ N. and $67^{\circ} 10'$ W. long. This port is singularly situated; it is separated from the elevated valley of Caraccas by a chain of mountains descending directly into the sea, and forming a rocky wall for the backs of the houses of the town, not much more than 140 toises from the ocean. On this account serious damage is sometimes occasioned by the stones that fall from the heights. This circumstance also occasions a striking peculiarity in the surrounding prospect, there being no visible horizon, except what the sea forms on the north. This town has only two streets running east and west, and parallel to each other, but not in a direct line; they are narrow and badly paved, and the houses generally mean. The place is defended by batteries, of which that of Cerro Colorado is the chief; and the works on the seaside are well disposed, and in good repair. The appearance of this town is singularly gloomy; one seems to be on an island, rocky and destitute of vegetation, and except Cape Blanco and Maiquetia, where there are a few cocoa trees, the horizon, the sea, and the heavens, are the only objects that meet the eye. The climate is the most ardent in all the country, not only from the scorching rays of the sun, but from the heat retained by the almost perpendicular rocks; and the air is considerably stagnated in the hollows of these mountains, and consequently has a more unwholesome effect upon the organs of the human frame, than the same degree of heat in the open country. By the thermometrical observations of Humboldt, it appears that La Guayra is one of the hottest places in the world, that the quantity of heat there, in the course of the year, is a little more than at Cumana; but that from November to January the atmosphere is cooler at La Guayra: probably this may arise from its more westerly position. This port, however, was not formerly so unhealthy, nor the yellow fever so prevalent as in Porto Cabello, Carthagena, and Santa Martha; but since the year 1797, to whatever cause it may be owing, this destructive malady has committed dreadful ravages. La Guayra is not a safe anchorage for ships; the depth of the water nearly a quarter of a league from the beach, is not more than eight fathoms; the sea is in constant agitation, and the surge runs high. It is,

consequently, difficult for vessels to take in their lading: this operation is done by the negroes and mulattoes, a remarkably strong race of men, who go up to their middles through the water; and it is particularly deserving of notice, that the sharks here, and at Santa Martha, are perfectly harmless, and never attack any one; while, at the opposite island, they are dangerous and blood-thirsty. The people, generally superstitious, attribute this to a bishop's having given his blessing to the sharks at both these places. In peaceable times the imports into this port amount to rather more than £500,000, and the exports of cacao, indigo, cotton, coffee, and hides, are nearly £350,000. 'When in the season of the great heat,' says the author of Colombia, 'we breathe the burning atmosphere of La Guayra, and turn our eyes towards the mountains, we are strongly impressed with the idea, that at the direct distance of 5,000 or 6,000 toises, a population of 40,000 souls assembled in a narrow valley, enjoys all the coolness of spring, of a temperature, which at night descends to 12° of the centesimal thermometer. This near approach of different climates is common in the Cordilleras of the Andes; but everywhere at Mexico, at Quito, in Peru and in New Grenada, a long journey must be made into the interior either by the plains, or by proceeding up the rivers, in order to reach the great cities, which are the centres of civilisation. The height of Caraccas is but a third of that of Mexico, Quito, and Santa Fe de Bogota; yet among all the capitals of Spanish America, which enjoy a cool and delicious climate in the midst of the torrid zone, Caraccas stands nearest to the coast. What a privilege to possess a sea-port at three leagues distance, and to be situated among mountains on a table land, which would produce a heat, if the cultivation of the coffee-tree were not preferred.'

Nothing can be finer than the road from La Guayra to the valley of Caraccas; it requires but three hours to travel it with good mules, and two to return; it takes about four or five hours to go on foot. It is very similar to that of St. Gothard, or of the Great St. Bernard in Switzerland; at first you ascend by a ridge of steep rocks, afterwards the ascent is rather more easy, and the windings of the road render the declivity more easy as in the old road over mount Cenis. The leap or Salto is a crevice that is crossed by a drawbridge, and on the top of the mountain there are real fortifications. At La Venta you find some most beautiful scenery; and when the clouds permit, the sea and the neighbouring coast present a magnificent prospect. You have an horizon of more than sixty-six miles in radius, the barren, white shore reflects the light in such a mass as to dazzle the beholder; while, at your feet, you see Cape Blanco, Maiquetia with its groves of cocoa-trees, La Guayra, and the vessels entering its port; and, when the sky is not clear, long trains of clouds, brightly illumined on their upper surface, present the appearance of islands floating on the ocean. Houses and trees are often seen bursting through the openings of the clouds, that are rolling one over another; and these objects thus appear at a greater depth, than when beheld through a serene atmosphere. Caraccas lies in a small valley near the lofty mountains of

Avila and the Silla, which give a character of gloom to its scenery, especially towards the end of the year; when the atmosphere in the evenings is thick, and when streams of vapors cling to the evergreen slopes of the hills. But in June and July the nights are delicious, the air is pure and transparent, and this is the season for enjoying the beauty of this scenery. The climate of the place is remarkably mild, the temperature in the day time being between 20° and 26° ; and at night between 16° and 18° , being favorable equally to the plantain, the orange-tree, the coffee-tree, the apple, the apricot, and to corn. It is, however, generally, inconstant and variable, the inhabitants complain of having several seasons in a day, and those in rapid succession. These variations act violently on the human frame. Two winds generally prevail, one from the west, or sea side, and the other from the east or the interior of the country; the first called Catia, because it blows from that place through the ravine of Tipe, is loaded with humid vapors, which it deposits, as its temperature decreases; it causes dreadful head-aches to persons of irritable nerves, and the people shut themselves up in their houses to avoid it, as they do the sirocco in Italy. The mean temperature of the air may be about from 20° to 22° . Rains are frequent, and hail occurs here about every four or five years, though none falls in the low regions of the tropics. The comparative coolness of the climate agrees well with the cultivation of equinoctial productions. The sugar-cane thrives even on the heights above Caracas; but in the valley the coffee-tree is preferred, which yields little fruit; but that little of the finest quality. Pine-apples of the highest flavor are produced at Baruto Empedrado, Buonavista, and on the way to Victoria. The traveller is surprised here with a sight of the culinary plants of our climates, and beholds the strawberry, the vine, and all the fruit trees of the temperate zone growing by the side of the coffee and banana tree. The best apples and peaches come from Macarao on the west of the valley, and the quince, not above four or five feet in height, has become wild. Excellent apples are sometimes produced from trees not grafted; there are no cherry-trees, and the olive-trees, though luxuriant in vegetation, bear little fruit. Four small rivers water the vicinity of Caracas, the Guayra on the south, the Anauco and the Carota on the east, and the Catucho; these, after supplying the domestic wants of the town, unite in one bed, and flowing through the valley Chacao, at length mingle with the Tuy, and under that appellation fall into the ocean about thirty-six miles east of Cape Codera. The streets are in straight lines about twenty feet wide, crossing each other at right angles, at a distance of 300 feet; there are three squares that deserve the name; the houses are well built, and in the interior there are many storied and of fine appearance, some of brick, but the greater part of stone, with sharp roofs. The houses of the principal people are neatly and even richly furnished.

Coro is another principal town in Venezuela: it is situated on an isthmus separating the Gulf Venezuela or Maracaibo, from the Carribean

Sea, eight leagues to the west of Caracas. It stands in a dry sandy plain, where scarcely anything grows but Indian figs, and plants of the Cactus family; the inhabitants have their fruit and vegetables from a place three leagues distant, and such is the great scarcity of water, that it is brought two miles on mules and asses into the town. It is, however, so well situated for trade with Porto Rico and St. Domingo, that the Spaniards fixed on it for their settlement on the coast of Terra Firma. Its streets are regular, but not paved, and the houses are mean; there are about 10,000 inhabitants, who possess little activity or enterprise, but are very proud of being descended from those who conquered the country. There are very few negroes; the Indians who live in the suburbs doing the laborious work; they are paid very low wages, and live with so much parsimony that they will not accommodate each other with a bit of fire without receiving a piece of wood in return. The next place of consequence is Porto Cavallo or Puerto Cabello, thirty leagues to the north-east of Caracas, in a fine harbour in the Golfo Triste; it is near Curacoa, to which island it owes its importance. About a league from Porto Cavallo is Barburata, a village and harbour, long infested by smugglers, but afterwards in the possession of the Guipuzcoa company, who built a town, wharf, and forts with immense warehouses, and ejected these most troublesome inmates. Guanara, ninety-three leagues south-west of Caracas, is situated in a fine plain towards Varinas; the river, which gives its name to the town, affords excellent water for the inhabitants and their cattle, and irrigates their land; while there is no impediment to prevent the free circulation of the air. This city has a number of uniform and regular streets, with well-built houses, a handsome church, and a good hospital; its population is about 12,000. It is surrounded with fertile lands and rich pastures for cattle, of which they keep great numbers, and in which, as well as mules, their chief trade consists. Formerly they raised good tobacco in some parts, which was a great source of riches.

The next place of importance is Barquisime-to, about 120 miles W. S. W. of Caracas, situated in an elevated plain, where it enjoys a happy temperature. It has a fine parish church, in which is a crucifix famed for working miracles, that is an object of devotion to the people, and yields an abundant revenue to the clergy. The town has a population of about 11,000 persons, who find sufficient employ in the plains, valleys, and rising grounds in the neighbourhood, in feeding cattle, and cultivating sugar and excellent wheat. Besides these there are Tocuyo, with about 10,000 inhabitants, who are said to be much addicted to suicide; San Carlos, a large and handsome town on the small river Aguaire, with a population of 9500 persons; Araura, with about 11,000 people, who are very indolent, and addicted to pleasure; Maracay, a beautiful town, forty miles south-west of Caracas, having three-fourths of its houses built of stone, with an industrious, cleanly, and moral population; Victoria, founded by the missionaries, in the plain of which, though very low, European corn is cultivated in large quantities by a popu-

lation of nearly 8000 persons; Tulmero, in a valley near that of Aragua, containing about 8000 inhabitants, many of whom are free Indians, who are active and laborious, but much addicted to strong liquors, in which they spend in one week the produce of two months; San Matheo, the inhabitants of which are rich and industrious; Valentia, about sixteen miles south-west of Caracas, remarkable as the scene of the death of the tyrant Lopez de Aguieme, who having declared against Philip II., at the moment when he fell, plunged a dagger into the bosom of his only daughter, that she might not have to blush before the Spaniards at the name of the daughter of a traitor. Here the ants are so innumerable, that their excavations under the houses resemble underground canals, which fill with water in the rainy season, and cause great danger to the buildings; San Felipe, surrounded with a fertile soil, watered by a great number of rivulets, and exposed to violent rains and excessive heats; Carora, a handsome town, having three parish churches, in a parched and thorny plain, but favored with a healthy climate; San Juan Baptista del Pao, a city inhabited solely by proprietors of cattle; Calabozo, round which it is computed about 98,000 head of cattle wander in the pastures; San Luis de Cuba, San Sebastian de los Reyes, both feeding large herds of cattle; Nirgua, erected on account of the mines in its soil, but which is going to decay; and the Bay of Ocumara, five leagues east of Porto Cavallo, which is an excellent port; the valleys round which contain a population of about 52,500 persons of different descriptions. The greater part of the inhabitants of these towns are farmers, who cultivate their lands, or feed numerous herds and flocks in the surrounding country; the rest are priests, physicians, escribanas (who discharge the offices of barristers, attorneys, notaries, and even bailiffs), and a few shopkeepers. The territory of one town or village is separated from that of another by forests and natural meadows, or savannahs; and occasionally we find missions or villages of half-civilised Indians.

The government of Cumana, including New Barcelona and New Andalusia, is bounded on the north and east by the sea, on the west by the river Unara, and on the south by the Orinoco, on the left bank of which there are some inhabitants in several places. It is very mountainous, the Andes running through it as far as the Gulph of Paria, and giving birth to the rivers that flow into the Caribbean Sea on the north, and into the Orinoco on the south. The Unara is navigable nearly twenty miles from the sea, up to the village of San Antonio de Clarinas, its whole course being about sixty miles. By the Neveri the port of Barcelona carries on its trade in cattle and skins; at Cumana the small river Manzanares is remarkable for having its banks lined with fruitful plantations. The soil in some parts is rather fertile; in others sandy, and presenting nothing but an inexhaustible mine of salt, both marine and mineral. In other places it is wonderfully fruitful, producing every species of vegetation, and the most precious trees, as the guaiacum, anacardium, Brasil, and Campeachy woods, down to the very coast of Paria. The climate varies

according to the different elevations of the mountains, valleys, and plains, in the interior. The most flourishing part of the country is the coast on the Gulf of Paria, where there are two villages, inhabited by French refugees and Spaniards, which are rising in importance; this district promises soon to be the richest in the province. The port of Cumana is capable of receiving all the navies of Europe, and the whole Gulf of Cariaco, thirty-five miles long, and sixty-eight broad, affords very good anchorage; the ocean being calm, and hurricanes never felt here. The city, situated at the foot of a hill, is commanded by the castle of St. Antonio, which forms a beautiful object to vessels advancing into the port, appearing as a bright object on the dark sides of the mountains that rise into the clouds. The town is only fifty-three feet above the level of the sea; the heat is very intense, and scarcely any rain ever falls in the plain, though in the neighbouring mountains it is frequent. There are no very remarkable buildings, owing to the dreadful effects of the last earthquake; on account of the frequency of these, the houses are low and slightly built, beauty and elegance being sacrificed to safety. In 1530 the whole coast was shaken, and a city called New Toledo destroyed; towards the end of the sixteenth century these shocks were very frequent, the sea sometimes rising fifteen or twenty fathoms; on the 21st of October, 1766, Cumana was overthrown, and great numbers perished; the tremblings continued hourly for fourteen months. The next year the inhabitants lived in the streets, when the shocks happened only once a month; in this earthquake the ground opened, and quantities of hot water were thrown out. In 1794 there was another tremendous convulsion, and in 1797 the earth heaved with frightful noises, and four-fifths of the city were destroyed. Half an hour before this there was a strong sulphureous smell, a loud noise was heard from under ground, and flames arose from the banks of the river. Though so constantly exposed to this dreadful visitation, the inhabitants of this place are very insensible to it; they think it never happens but at certain intervals, and that the weather and other appearances indicate its approach. The population of this town, comparing all the statements that have been given, may be about 17,000; they are not so rich as the Caraccans, but they are inclined to business, economical, and industrious; they trade abundantly in cattle, smoked meat, and salted fish; the retail trade is mostly carried on by Catalans, Biscayans, and Canarians, men who begin with a few dollars, and in a few years acquire fortunes by frugality and industry. These people first taught the natives to derive advantage from their local productions.

Provisions are remarkably cheap here; 'two pounds of beef,' says the author of Colombia, 'are sold at Cumana for twopence-halfpenny; and twenty-two pounds of salt meat at from three shillings and fourpence to four shillings and twopence. Fish is never weighed there: some days there is such a quantity caught by the fishermen, that they give ten, twelve, or fifteen, pounds weight for fivepence. The poor go to the

sea-side with maize, cakes, and eggs, and barter them for fish. Eggs are the small change in Cumana, Caracas, and other provinces of Venezuela, where copper coin is unknown; the smallest piece in circulation being a medio-real in silver, worth twopence-halfpenny. If one goes into a shop to buy something worth less than twopence-halfpenny, they give as change two or three eggs; for a dozen of eggs there is worth only twopence-halfpenny. That is also the price of a measure of excellent milk, about a quart. A sheep is sold for a dollar; a fine turkey for twenty or twenty-five pence; a fowl for fivepence; a fat capon for from sevenpence-halfpenny to tenpence; a duck at the same price; game and wild-fowl are frequently sold cheaper than butcher's meat; and all those articles are still cheaper in the small towns of the interior.

'I lived,' says Lavaysse, 'at the best and dearest hotel in Cumana, at a dollar per day, including the expenses of my son and servant. They gave us for breakfast, cold meats, fish, chocolate, coffee, tea, and Spanish wine: an excellent dinner, with Spanish and French wines, coffee, and liqueurs: in the evening chocolate; I was well lodged and lighted. I should have expended but half that sum if I had gone to board and lodge in a family. In short, there is not a country in the world where one may live cheaper than in the province of Cumana. An excellent dinner may be had there for tenpence, not including wine, which does not cost more than fivepence per bottle to those who buy a quantity of it. Poor people drink punch, which is at a very low rate, for it does not cost above one penny per quart.'

The following description of the new salt-works in the neighbourhood of Araya, from the same pen, is worthy of attention. 'The new salt-works of Araya have five reservoirs or pits, the largest of which have a regular form, and 2300 square toises surface. Their mean depth is eight inches. Use is made both of the rain waters, which by filtration collect at the lowest part of the plain, and of the water of the sea, which enters by canals, or martellières, when the flood-tide is favored by the winds. The situation of these salt-works is less advantageous than that of the mere. The waters which fall into the latter pass over steeper slopes, washing a greater extent of ground. The natives make use of hand-pumps to convey the sea-water from one principal reservoir into the pits. It would nevertheless be easy enough to employ the wind as the moving power, since the breeze always blows strong on these coasts. The earth already washed is never carried away here, as is the custom from time to time in the island of Margarita; nor have wells been dug in the muriatiferous clay, to find strata richer in muriate of soda. The salt men generally complain of want of rain; and in the new salt-works it appears difficult to determine what is the quantity of salt that is owing solely to the waters of the sea. The natives estimate it at a sixth of the total produce. The evaporation is extremely strong, and favored by the constant motion of the air; so that the salt is collected in eighteen or twenty days after the pits are filled. Humboldt found (the 19th of

August, 1799, at three in the morning) the temperature of the salt water in the pits 32·5°, while the air in the shade was 27·2°, and the sand on the coast at six inches depth 42·5°.

The royal administration of the salt-works of Araya, dates only from the year 1792. Before that period they were in the hands of Indian fishermen, who manufactured salt at their pleasure, and sold it, paying the government the moderate sum of 300 piastres. The price of the fanega was then four reals (eight of these reals are equivalent to a piastre, or 105 sous French money, or 4s. 4½d. English); but the salt was extremely impure, gray, mixed with earthy particles, and surcharged with muriate and sulphate of magnesia. As the manufacture or labor of the salt-makers was also carried on in the most irregular manner, salt was often wanted for curing meat and fish—a circumstance that has a powerful influence, in these countries, on the progress of industry, as the lower class of people live on fish, and a small portion of *tasajo*. Since the province of Cumana has become dependent on the intendancy of Caracas, the sale of salt is under the excise; and the fanega, which the Guayquerias sold at half a piastre, costs a piastre and a half. This augmentation of price is slightly compensated by a greater purity of the salt, and by the facility with which the fishermen and farmers can procure it in abundance during the whole year. The salt-works of Araya yielded the treasury in 1799 a clear income of 8000 piastres.'

The other towns of any note in this province are Barcelona, a place of growing importance, especially in a commercial view; Cariaco, surrounded with extremely fertile plains, but of a hot and unhealthy climate; Carupano, built at the opening of two fine valleys, watered by two large rivers; Rio Caribe, whose valley is the temple of this country; Cumanacoa, surrounded with high mountains, and of rather a cold climate, though it is not more than 104 toises above the level of the sea; and several missionary establishments near the rivers and on the great plains, inhabited chiefly by Indians, who live in mud-huts, and cultivate their gardens, together with a large plot of ground which is common to all, and which is generally an indigo or sugar plantation. Near Cumanacoa is the great mountain Tumiriquiri, a vast rocky wall, rising from the forest; in one part the chain is broken by a precipice 900 feet wide, filled with trees, whose branches entwine completely with each other; through this crevice the Rio Jagua flows, and it is the abode of the jaguar, or American tiger, which is here very large and ravenous. Flames occasionally issue from two caverns in this precipice that may be seen at a great distance. The mountain is about 4400 feet above the level of the sea; its paths are traversed on mules, which are so sure footed, that an accident seldom happens. In a valley near this ridge is the cave of Guacharo, with a river running through it nearly thirty feet wide, and inhabited by a vast number of nocturnal birds, who build their nests in its arches. Once a-year the Indians destroy the young for the sake of a layer of fat, which covers the abdomen, which is perfectly free from

smell, and will keep for twelve months without becoming rancid. The monks purchase this oil for the purpose of cooking. These birds, called guacharoes, utter a mournful cry, which the Indians ascribe to the souls that are forced to go through this cave to the other world.

'They consider,' says Humboldt, 'that they are enabled to obtain permission to go out only when their conduct in this life has been without reproach. If it has been otherwise, they are retained for a shorter or longer time, according to the heinousness of their offences. This dark, wretched, and mournful abode, draws from them the mournings and plaintive cries heard throughout.'

'The Indians have so little doubt of this fable, supported by tradition, being a sacred truth, commanding the utmost respect, that, immediately after the death of their parents or friends, they repair to the mouth of the cavern to ascertain whether their souls have met with any impediment. If they think they have not distinguished the voice of the deceased, they withdraw overjoyed, and celebrate the event by inebriety, and dances characteristic of their felicity; but, if they imagine they have heard the voice of the defunct, they hasten to drown their grief in intoxicating liquors, in the midst of dances adapted to paint their despair. So, whatever may be the lot of the departed soul, his relations and friends give themselves up to the same excesses: there is no difference but in the character of the dance.'

'All the Indians of the government of Cumana and Orinoco not converted to the faith, and even many of those who appear to be so, have, notwithstanding, as much respect for this opinion as their ancestors could possibly have had. It appears that it is not, like so many others of its kind, the child of imposture or fanaticism; for it is not accompanied with any religious ceremony, the expense of which would increase the revenue of the inventor's benefice. The cavern itself shows no vestige of superstition having at any time obtained there the least monument of the empire imposture might have wished to exercise over credulity. This prejudice then is solely the effect of fear, ever ingenious in creating phantoms, and in imagining those things which flatter the illusion. Among the Indians 200 leagues from the cavern, to go down into Guacharo, is synonymous with *to die*.'

The forests of this country abound in monkeys of every kind, the most remarkable of which is the araquato, about three feet high, having its whole body covered with a thick coat of fur of a reddish-brown color; its face is rather black, and its beard long, and its eye, voice, and gait very melancholy. It is not vivacious as monkeys generally are, and the noise it makes, especially on an approaching change of weather, is singularly dismal. The valleys and banks of the rivers abound in Brasil and log-wood. The population of Barcelona and Cumana is about 100,000, one half of whom are Indians.

The island of Margarita forms a separate government from that of Cumana; it is situated in 10° 56' N. lat., and 64° and 65° W. long., being about forty-eight miles long and eighteen broad. It was famous for pearls, but the fishery has ceased for more than a century past. This island con-

sists of two parts, united by an isthmus, scarcely more than from eighty to 100 paces broad, and in some places not more than ten or twelve feet above the sea. There are three ports in the island, Pampetar, Puerto de la Mar, and Puerto del Norte; the former being the most important for its trade. The population is about 16,000. It has only three rivulets, just sufficient to turn mills; the water of the little river near Assumption is impregnated with sulphureted iron, magnesia, &c., so that the inhabitants prefer drinking water from ponds, though it is always muddy. There is scarcely enough agriculture to maintain the people. Provision is cheaper here than at Cumana.

This island is famous for parrots and other rare birds; scarcely a vessel leaves its ports without carrying away some of them. The manufactures are cotton stockings and hammocks of a peculiarly excellent quality; but the fisheries are the principal objects of trade; more than 300 Indians are employed in them; the quantity taken is incredible, and of innumerable kinds, the most common being the mullet, something like a herring. Salt is remarkably cheap; a barrel, of about 300 pounds, selling for twelvepence-halfpenny.

The province of Maracaibo, round the lake of that name, extends but a little way into the land: it is about 100 miles in length. The soil is unfruitful on the east and west shores; but, on the south, it is equal to that of the finest land in South America; the climate is generally hot and unhealthy, except in the south, near the snowy mountains of Merida. It is peopled by about 174,000 persons, chiefly Indians; a few whites only have settled on the borders of the lake towards the west. The towns on this lake are mostly built on posts of iron-wood, which becomes like a mass of stone from the quality of the water. The city of Maracaibo stands about six leagues from the sea, in a dry hot climate and on a sandy soil. The south wind, from its insalubrity, is here called the Destroyer; violent storms of thunder and lightning, with deluges of rain, are prevalent; but they are desirable, as, in failure of them, earthquakes are experienced. The town is built on the shore of a small gulf near Maracaibo Point; many of the houses are built of lime and sand, but however cheap tiles are, the inhabitants, from an idea of greater safety, obstinately adhere to the practice of covering the handsomest with a kind of reed called enea, growing on the borders of the lake. This mixture of reeds and tiles has a disagreeable effect, and from their combustible nature, they keep the city in constant danger. The most noble families are the descendants of the first conquerors; of these there are more than thirty, but most of them are poor, and the sense of their high extraction makes them ashamed of labor, and remarkably indolent. There are about 25,000 inhabitants, of which 5000 are negroes, who are all artisans of different descriptions.

'Notwithstanding the barrenness of resources which education finds at Maracaibo,' Depons says, 'we there see young persons so favored by nature, that the slightest elementary instruction at once develops in them all the faculties, which

in Europe do not manifest themselves until after long study, and the care of the best teachers. What adds to the singularity of the phenomenon is, that this excess of natural genius frequently becomes prejudicial to the tranquillity of the families of Maracaibo; for it is enough for many of these young men to know the conjugation and government of the verbs, in order to be qualified to write pieces, whose subtilty would appear to the knavish advocate better than the productions of the counsel who establishes his reasons on the principles of the civil law. Such suits as should never have been instituted, or which the tribunals would instantly have decided, become interminable and ruinous by the sophisms with which these scribblers envelope in darkness causes the most simple and clear. This disease, very prevalent at Maracaibo, is by no means a stranger in other Spanish territories. The penal laws which the legislature has been forced to enact, to lessen the number of these imps of chicane, whom they call *pendolistas* (quick writers), literally prove that the evil is general enough.

‘In allowing that the inhabitants of Maracaibo have activity, courage, and genius,’ says the same writer, ‘we have nothing more to say in their favor. They are reproached with having very little regard to their word, and with thinking themselves not bound by their signature, until after they have in vain endeavoured to release themselves from it by law. Their reputation in this respect is so well established, that all strangers whom business draws to Maracaibo, say it is much better to form connexions of interest with the women than with the men, because they alone have there that good faith and firmness which, in every other part, is the peculiar heritage of the men.’

‘Since the course of description has led me,’ he adds, ‘to speak of the women of Maracaibo, I ought not to let it be unknown that they are in their youth paragons of modesty; and in marriage, faithful wives, and excellent mothers of families. Affection for their husbands, the cares of their household, and the education of their children, are the objects which divide all their moments, and occupy all their solitude. They know not, however, before marriage, any other amusement than music. Their favorite instrument is the harp. There are few houses in which the harmonious sound of this instrument is not heard every evening, and every day of festival.’

The other towns of this province are Truxillo, Gibraltar, Paruate, Las Barbacoas, and San Pedro; Truxillo is celebrated for superior woollen manufactures, and excellent cheese.

Guiana, or Guayana, is an immense province, the precise boundaries of which cannot be ascertained. On the east, its shore extends to the mouth of the Orinoco, about thirty leagues, and westward it reaches to the river Yapura; besides which, it stretches along the Orinoco 400 leagues to the Rio Portuguesa. Besides this vast river, it has the Caroni, the Aruy, and the Caura, on the north; on the south, the Guaviare, the Yuritta, and the Atalapo; and, on the west, the Suapure, the Sippapu, besides a multitude of smaller streams. This province is divided into upper and lower, one east and the other west of

the Caroni. The soil is fertile in the extreme, the rivers periodically overflowing their banks, and leaving behind them a slime as prolific as the Nile; but this fine district is nearly waste, and a harbour for a number of cannibal tribes, of which the Caribs are the most formidable. The indigenous inhabitants are about 30,000, united into missions, the rest are independent Indians, who have not embraced Christianity; in the whole, constituting a population of 52,000 persons. Cattle constitute the riches of the province, in the export of which, and of a little tobacco, cotton, and indigo, their trade consists. Angostura is the chief place; it is about fifty leagues west of the confluence of the Caroni; when the water is high, the quays are frequently overflowed, and the caymans or crocodiles are sometimes seen in the streets. Notwithstanding its low situation it enjoys a mild temperature, Reaumur’s thermometer scarcely rising to 24° in the hottest season.

The province of Varinas divides the territories of the former government of Caracas from those of Cundinamarca. It is intersected by large and numerous rivers, which inundate and fertilise its extensive plains. In one of the mountainous ridges of the country the Apure rises, which, after running a course of more than 500 miles, falls into the Orinoco by several mouths, receiving on its way the waters of numerous other streams, the largest of which are the Santo Domingo and Portuguese. Here also the Aranca and the Meta are among the fine rivers that intersect this country. Its total population amounted in 1807, to 141,000. The most remarkable features are its extensive plains, covered with luxuriant herbage and feeding innumerable herds of cattle. Its chiefs towns are Varinas, San Jayme, San Fernando de Apure, Pedraga and San Antonia.

Santa Fé lies on the west of the eastern Andes; it is very mountainous, but none of the summits of the chain in this country reach the region of eternal snows, though they are very near it. The lake Guatavita is one of the curiosities of this province. The following description of it is from the work entitled Colombia:—

‘It is situate on the ridge of the Zipaquirá mountains, north of the capital, in a wild and solitary spot, at the height of more than 8700 feet above the sea. It is a small oval piece of water, in a deep hollow of the same form, round which are cut ranges of steps, reaching to the brink of the lake, having served most probably for some religious ceremonies in use among the ancient possessors of this country. As it was supposed that a great quantity of treasure had been thrown into this lake, when Quesada, conquered the kingdom of Cundinamarca, the Spaniards attempted to cut a canal through the mountain of which its banks are composed, in order to drain off the waters; but their design does not appear to have succeeded, for, after considerable excavations, it has been left off at little more than half the requisite depth.’

The same work thus describes two other grand natural objects in this country:—

‘The cataract of the Tequendama, by which the river Funza joins the great Magdalena, is the most noted object in the country near the capital.

The Funza, or Bogota, after receiving the waters of the numerous small rivers which flow through the great plain, is about 140 feet in breadth, a short distance above the fall; approaching the crevice through which it dashes, its breadth is diminished to thirty-five, when, with accumulated force, it rushes down a perpendicular rock at two bounds, to the astonishing depth of 600 feet, into a dark and unfathomable gulf, out of which the river again issues under the name of Rio Meta, and continues its course, by an immense descent, till it joins the great river of Magdalena.

The crevice of Icononzo is in the centre of the valley of Pandi, and appears to have been formed by some convulsion of nature, which has rent asunder the mountain. At the height of nearly 300 feet above the torrent (which forms beautiful cascades on entering and quitting the crevice) are seated these extraordinary bridges, one under the other; the breadth of the upper one being about forty feet, and its length upwards of fifty, composed of solid rock, in the form of an arch, seven or eight feet thick at its centre. Below this, and rather advanced on one side of it, at the depth of sixty feet, is another bridge, formed still more singularly; for as the mountain appears to have been rent away, or drawn from the upper, the inferior one seems to have fallen from the mountain, and three enormous masses of rock have descended from the opposite sides of the chasm, in such a manner that the upper mass forms the key of the other two. This lower bridge cannot be visited without much risk, as a narrow path alone leads to it along the brink of the precipice. In the centre is a hole, through which the abyss below can be seen, and numberless flights of nocturnal birds are observed hovering over the water, which flows through so dark a cavern that the sides cannot be distinguished.

Bogota, the capital of this province, is a large and handsome city, with about 30,000 inhabitants; the plain in its neighbourhood is so fertile that it yields two harvests in the year. Here is one of the mints of Cundinamarca, the other is at Popayan. Besides the capital there are Tocaima, La Villa de la Purification, Honda, Mariquita, Muzo, Tunja, Leiva, Velez, San Gil, and Socorbo. This province is famed for its gold, silver, gems, salt, and coal, and for its fruitful plains, which breed numbers of horses, and mules, which are exported to Peru. The woods abound with game and wild animals, and the rivers with fish and alligators.

After these, in their order, are the provinces of Merida with its capital of the same name—of Santa Marta, with its immense and rapid rivers, crossed by bridges made of the roots of plants twisted together into immense ropes and stretched over them—Cartagena, of which copious mention has been made in the article AMERICA—Daríen, on the gulf of that name—Panama, consisting of abrupt and broken chains of mountains, between two seas, being for the most part covered with thick forests—Veragua, the most northerly of the provinces of Tierra Firme, a mountainous and rugged country, with vast forests, interspersed with rich and fruitful valleys—Choco, the peculiarities of which we have al-

ready mentioned—Antioquia, famous for its gold mines, worked by 800 negroes—San Juan de Los Llanos—the large province of Popayan, in which is a pass of the Andes, 11,499 feet above the level of the sea, and not more than a foot and a half broad, where travellers can with the greatest difficulty pass each other—Quixos—Jaen de Bracamoras—Maynas—Quito—San Miguel de Ibaña—Otobaló—Latacunga—Riobamba—Chimbo—Guyaquil—Cuenca—and Loxa. Quito is famous for the loftiest summits of the Andes, of which we have already spoken, and for the volcanoes of Pichincha and Cotopaxi, the loftiest volcano in the world.

A most singular monument is observable on the top of the dike or chain of Tiopullo, consisting of a tumulus, and the ruins of one of the Peruvian palaces called *tambos*, situate in a plain covered with pumice-stones. The tumulus, if it be one, is upwards of 200 feet high, and is supposed to have been the burying-place of a chief. The palace is south-west of this hillock, nine miles from the crater of Cotopaxi, and thirty from Quito. It is in the form of a square, each side being about 100 feet in length, with four great door-ways, and eight chambers. Its walls are more than three feet thick, formed of large stones, regularly cut and laid in courses, and the whole is in tolerable preservation. It is called the palace of Callo. The great curiosity of this edifice consists in the beauty of the workmanship, as all the stones are cut into parallelepipeds, and laid in regular courses, and so nicely joined, that were it not that each stone is convexly and obliquely cut on the outside, their joints would not be visible.

Quito is about 9510 feet above the level of the sea, having behind it the conical summit of Javirac, immediately under that of Pichincha.

The state of society in this country is much improved, and is still ameliorating. On this subject we shall make a short extract from captain Hall's concise and interesting work, and with this we must conclude, though much more might be said on so fruitful a subject.

Under the Spanish government the political distinctions, which separated these various classes of inhabitants, were almost as numerous as, and infinitely more odious than, their physical varieties of features and complexion. By the laws of the Indies, the Indians were not only cut off from every civil employment or distinction, but were even denied the dignity of rational beings, being held in a state of perpetual pupilage, under the authority, principally, of their curates, who would hardly permit them to hold any intercourse with the rest of the inhabitants; the people of color were little better treated: besides being rigidly excluded from every employment of honor or consideration in the state, they were subjected to personal distinctions, the more painful because they could have no other object than that of gratifying the vanity of the privileged class at the expense of their unfortunate brethren. Such was the law prohibiting the women of color from wearing the manto, or black dress used at church, or from wearing any ornament of gold or silver; custom, besides, prohibited them the use of the alfombra, or carpet, at their devotions, and that

of an umbrella to screen them from the sun in the streets; all these distinctions are now happily abolished; the law of the republic sees none but citizens in every class of inhabitants, whatever may be their origin or the tinge of their complexions: the justice of this policy has been rewarded by the exertions of the people of color in aid of the independence of the country, of which they have been the firmest supporters, and Co-

lombia reckons among her best and bravest officers, men whom Spanish pride and tyranny deemed unworthy to sit at a white man's table. If any lingering prejudices still remain they are happily confined to female coteries, or an occasional explosion in a ball-room; even these last embers of irritated and childish pride it is the interest of the republic to see extinguished.'

COLONNA (Fabius), a very learned botanist, born at Naples, about the year 1567. He became skilled in the languages, in music, designing, painting, and the mathematics; and died about the middle of the seventeenth century. He wrote, 1. *Φυτοζασανος*, seu *Plantarum aliquot* (ac piscium) *Historia*; 2. *Minus cognitarum rariorumque Stirpium εκφρασις*; itemque de *aquatilibus*, alisque nonnullis animalibus, *Libellus*; and other works.

CO'OLON, *n. s.* *κωλον*, a member; a point in grammar; see below. The greatest and widest of the intestines.

Now, by your cruelty hard bound,

I strain my guts, my *colon* wound. *Swift.*

The contents of the *colon* are of a sour, fetid, acrid smell in rabbits. *Floyer on the Humours.*

COLON, in grammar. Grammarians generally assign the use of a colon to be, to mark the middle of a period; or to conclude a sense less perfect than a dot or period. Others say, a colon is to be used when the sense is perfect, but the sentence not concluded.

COLON, in anatomy, from *κωλος*, hollow, the name given to the greater portion of the large intestine. It begins where the ilium ends, in the cavity of the os ilium on the right side; thence ascending by the kidney, on the same side, it passes under the concave side of the liver, to which it is sometimes tied, as likewise to the gall-bladder, which tinges it yellow in that place; then it runs under the bottom of the stomach to the spleen in the left side, to which it is also knit; from thence it turns down to the left kidney; and thence passing, in the form of an S, it terminates at the upper part of the os sacrum, in the rectum. See **ANATOMY**.

CO'LO'NEL, *n. s.* } Of uncertain etymology.
CO'LO'NELLING, } *gy*. Skinner imagines it
CO'LO'NELSHIP, *n. s.* } originally *colonialis* the
 leader of a colony. Minshew deduces it from
columna, a pillar: as *patriæ columnen*; *exercitus columnen*.

The chiefest help must be the care of the *colonel* that nath the government of all his garrison.

Spenser on Ireland.

Captain or *colonel*, or knight in arms,
 Whose chance on these defenceless doors may seize,
 If deed of honour did thee ever please,
 Guard them, and him within protect from harms.

Milton.

Then did Sir Knight abandon dwelling

And out he rode a *colonelling*. *Butler's Hudibras.*

Whilst he continued a subaltern, he complained against the pride of *colonels* towards their officers; yet, in a few minutes after he had received his commission for a regiment, he confessed that *colonelship* was coming fast upon him. *Swift.*

COLONEL, in military affairs, the commanding officer of a regiment, and next in rank to a general. A colonel of a regiment, properly so called, is the nominal head of a given number of men; the clothing, &c. of whom is exclusively entrusted to him, as well as the appointment of an agent, who receives the pay and subsistence of the corps, but for whose solvency and character the colonel is responsible to the public. In the French and Spanish armies, this title is confined to the infantry and dragoons: the commander of a regiment of horse they usually call *maitre de camp*. A colonel may put an officer of his regiment in arrest, but must acquaint the general with it. He is not allowed a guard, but only a sentry from the quarter-guard. In his absence the lieutenant-colonel commands.

COLONEL-LIEUTENANT, the second in command in a regiment, whereof the king, prince, or other person of the first eminence, is colonel. These colonel-lieutenants have always a colonel's commission, and are usually general officers.

COLONEL BY BREVET, one who has obtained the rank of colonel in the army, without having that rank in any particular regiment.

COLONIA, in ancient geography, a town of the Trinobantes, a little above Camelodunum: now Colchester in Essex, according to Camden, who supposes it to take its name from the river Coln, and not that it was a colony: though others think Antonine's distances agree with Sudbury.

COLONIA EQUESTRIS, in ancient geography, a noble colony on the Lacus Lemanus. It appears to have been the work of Julius Cæsar, who settled there *Equites Lemitanei*: and to this Lucan is thought to refer. By the Itinerary it is supposed to have stood between Lausanne and Geneva, twelve miles from the latter, by Peutinger's map; which directs to Noyon, placed in Cavo Lemano, according to Lucan's expression, that is, a bay or cove of the lake. Its ancient name was *Noviodunum*; hence its modern name, Noyon, or, as some suppose, Nevers.

COLONIA METELLINA, a town of Lusitania, situated on the right or west side of the Anas or Guadiana; but now on the left or east side, from the river's shifting its bed or channel, and called *Medelin*, a town in Estremadura.

COLONIA MORINORUM, a town of Gallia Belgica, thought to be Tarvenna, the capital of the Morini; now called Terrouen.

COLONIA NORBENSIS, or *NORBA CÆSAREA*, a town of Lusitania, south of Trajan's bridge on the Tagus: now Alcantara, in Estremadura.

COLONIA TRAJANA, a town of Belgica, called also *Ulpia*, and *Tricesima*, from being the station of the thirtieth legion; now Kellen, in Cleves

COLONIA VALENTIA, a town of Spain, on the Turias; destroyed by Pompey, and restored by Julius Cæsar; still called Valencia.

COLONNA'DE, *n. s.* Ital. *colonna*, a column; a series of columns disposed in a circle, and insulated within side; any series or range of pillars.

Here circling *colonnades* the ground inclose,
And here the marble statues breathe in rows.

Addison.
For you my *colonnades* extend their wings. *Pope.*

COLONNADE, POLYSTYLE, is that whose number of columns is too great to be taken in by the eye at a single view. Such is the colonnade of the palace of St. Peter's at Rome, consisting of 284 columns of the Doric order, each above four feet and a half diameter, all in Tiburtine marble.

COLONOS, in ancient geography, an eminence near Athens, whither Ædipus, after his banishment from Thebes, is said to have retired: and hence Sophocles calls the tragedy on that subject, Ædipus Coloneus. A place sacred to Neptune, and where stood an equestrian statue of him. Here also stood Timon's tower: who, for his love of solitude, and hatred to mankind, was called Misanthropos.

COLONSA, or COLONSAY, one of the Western Islands of Scotland, so named from Colon, a popish saint, lying in the Atlantic Ocean, between the coast of Argyllshire and that of Ireland, four miles and a half west of Jura. It is separated from Oronsay by a narrow sound, which is dry at low water, and therefore both islands appear as one. They are both flat, compared with the towering peaks of Jura and Mull, though there is a considerable number of rugged heath-covered hills in them. They measure about 8000 acres, of which 3000 are arable. The air is pure and salubrious; the soil light and fertile. The best part of the ground maintains a fine breed of black cattle. There is a great quantity of fine coral on the banks round these islands, and a considerable quantity of kelp is annually made from the sea-weed thrown upon the coast. These islands constitute the west division of the parish of Jura and Colonsay.

COLONUS, a husbandman, or villager, who was bound to pay yearly a certain tribute, or at certain times of the year to plough some part of the lord's land; and from thence comes the word clown.

CO'LONY, *n. s.* } Lat. *colonia*. A body of
CO'LOXIZÉ, *v. a.* } people drawn from the mother country to inhabit some distant place. The place itself by a metonymy; to plant with inhabitants; to settle with new planters.

There was never an hand drawn, that did double the rest of the habitable world, before this; for so a man may truly term it, if he shall put to account as well that that is, as that which may be hereafter, by the farther occupation and *colonizing* of those countries: and yet it cannot be affirmed, if one speak ingenuously, that it was the propagation of the Christian faith that was the adamant of that discovery, entry, and plantation; but gold and silver, and temporal profit and glory; so that what was first in God's providence, was but second in man's appetite and intention.

Bacon's Holy War.

Druina hath advantage by acquést of islands, which she *colonizeth* and fortifieth daily. *Howel's Vocal Forest.*

To these new inhabitants and *colonies* he gave th same law under which they were born and bred.

Spenser on Ireland.

Rooting out these two rebellious sept's, he placed English *colonies* in their room. *Davies on Ireland.*

The rising city, which from far you see,
Is Carthage and a Tyrian *colony*. *Dryden's Virgil.*

Osiris, or the Bacchus of the ancients, is reported to have civilized the Indians, planting *colonies*, and building cities. *Arbutnot on Coins.*

While Chrysoloras admired the venerable beauties of the mother, he was not forgetful of his native country, her fairest daughter, her imperial *colony*.

Gibbon.

COLONY is a term that has been applied to three different kinds of emigrants, viz. 1. Those who leave their native country, when its inhabitants are become too numerous. 2. Those established by victorious princes among vanquished nations, to keep them in awe and obedience. 3. Colonies of commerce, of which the sole object is the extension of trade. I. By the first kind of colonies, some ages after the deluge, the east first, and successively all the other parts of the earth, became inhabited; and not to mention the Phœnician and Grecian colonies, so famous in ancient history, it is notorious that it was for the establishment of such colonies, that, during the declension of the Roman empire, those torrents of barbarous nations, issuing mostly out of the north, overran Gaul, Italy, and the other southern parts of Europe; and, after many bloody battles, shared it with the ancient inhabitants. II. The second kind of colonies were planted by the Romans more than any other people, to secure the numerous conquests they had made. The inhabitants of many cities in France, Germany, Spain, and even England, still value themselves on their having been originally Roman colonies. There were two kinds of colonies among the Romans; those sent by the senate; and the military ones, consisting of old soldiers, disabled by the fatigues of war, who were thus provided with lands as the reward of their services. The colonies sent by the senate were either Roman or Latin, i. e. composed either of Roman citizens, or Latins. The *coloniae Latine* were such as enjoyed the *jus Latii*; viz. 1. that whoever was edile or prætor in a town of Latium, became for that reason a Roman citizen; and, 2. that the Latins were subject to edicts of their own, and not to those of the Roman magistrates. The *coloniae Romanae*, were such as had the *jus Romanum*, but not in its full extent; i. e. they had no right of suffrage, putting up for honors, magistracies, command in the armies, &c.; but the *jus Quiritium* only, or private right; as rights of liberty, sacrifice, marriage, &c. For it was long a rule, never to grant the liberty of the city in full to colonies. There were other colonies, which had little more than the name; only enjoying what they called *jus Italicum*, i. e. freedom from the taxes paid by the provinces. Such were the colonies of Tyre, Berytus, Helopolus, Palmyra, &c. M. Vaillant has filled a volume in folio with medals struck by the several colonies, in honor of the emperors who founded them. III. The colonies of commerce are those established in modern times by the English, French, Spaniards, Portuguese,

Dutch, &c.; partly, certainly, for the motives already enumerated, and the peculiar condition of the mother country; but that have been mainly encouraged and protected by their home governments for the extension of trade.

The practice of settling commercial colonies in distant countries has been adopted by the wisest nations of antiquity, who acted systematically upon maxims of sound policy. This appears to have been the case with the ancient Egyptians, the Chinese, the Phœnicians, the commercial states of Greece, the Carthaginians, and even the Romans; for though the colonies of the latter were chiefly military, it could easily be shown that they were likewise made use of for the purposes of trade. The savage nations who ruined the Roman empire, sought nothing but to extirpate and hold in vassalage those whom they overcame; and, therefore, whenever princes enlarged their dominions at the expense of their neighbours, they had recourse to strong forts and garrisons to keep the conquered in awe. Machiavel labors to show, that the settling of colonies would have been a cheaper and better method of bridling conquered countries, than building fortresses in them. John de Witt, who was one of the ablest and best statesmen that ever appeared, strongly recommended colonies; as affording a refuge to such as had been unfortunate in trade; as opening a field for such men to exert their abilities, as through want of interest could not raise themselves in their own country; and as a supplement to hospitals and other charitable foundations, which he thought in time might come to be overcharged. Some, however, have ridiculed the supposed advantages of colonies, and asserted that they must always do mischief by depopulating the mother country. The history of our American colonies undoubtedly shows, that when colonists become numerous and opulent, it is very difficult to retain them in subjection to the parent state. It becomes then a question not easily answered, how far they are entitled to the rights they had as inhabitants of the mother country, or how far they are bound by its laws? Judge Blackstone says, 'Plantations, or colonies in distant countries, are either such where the lands are claimed by right of occupancy only, by finding them desert and uncultivated, and peopling them from the mother country; or where, when already cultivated, they have either been gained by conquest, or ceded to us by treaties. And both the rights are founded upon the law of nature, or at least on that of nations. But there is a difference between these two species of colonies with respect to the laws by which they are bound. For it has been held, that if an uninhabited country be discovered and planted by English subjects, all the English laws then in being, which are the birthright of every subject, are immediately there in force. But this must be understood with many and very great restrictions. Such colonists carry with them only so much of the English law as is applicable to their own situation, and the condition of an infant colony: such for instance, as the general rules for inheritance, and of protection from personal injuries. The artificial refinements and distinctions incident to the

property of a great and commercial people, the laws of policy and revenues (such especially as are enforced by penalties), the mode of maintenance for the established clergy, the jurisdiction of spiritual courts, and a multitude of other provisions, are neither necessary, nor convenient for them, and therefore are not in force. What shall be admitted, and what rejected, at what times, and under what restrictions, must, in cases of dispute, be decided in the first instance by their own provincial judicature, subject to the revision and control of the king in council; the whole of their constitution being also liable to be new modelled and reformed by the general superintending power of the legislature in the mother country. But in conquered or ceded countries, that have already laws of their own, the king may indeed alter and change those laws; but, till he does actually change them, the ancient laws of their country remain, unless such as are against the law of God, as in an infidel country.' Dr. Adam Smith thus argues against what has been called, in modern times, the colonial system.

'The European colonies of America have never yet furnished any military force for the defence of the mother country. The military force has never yet been sufficient for their own defence; and in the different wars in which the mother countries have been engaged, the defence of their colonies has generally occasioned a very considerable distraction of the military force of those countries. In this respect, therefore, all the European colonies have, without exception, been a cause rather of weakness than of strength to their respective mother countries.

'The colonies of Spain and Portugal only have contributed any revenue towards the defence of the mother country, or the support of her civil government. The taxes which have been levied upon those of other European nations, upon those of England in particular, have seldom been equal to the expense laid out upon them in time of peace, and never sufficient to defray that which they occasioned in time of war. Such colonies, therefore, have been a source of expense and not of revenue to their respective mother countries.

'The advantages of such colonies, to their respective mother countries, consist altogether in those peculiar advantages which are supposed to result from provinces of so very peculiar a nature as the European colonies of America; and the exclusive trade, it is acknowledged, is the sole source of all those peculiar advantages. In consequence of this exclusive trade, all that part of the surplus produce of the English colonies, for example, which consists in what are called enumerated commodities, can be sent to no other country but England. Other countries must afterwards buy it of her. It must be cheaper therefore in England than it can be in any other country, and must contribute more to increase the enjoyments of England than those of any other country. It must likewise contribute more to encourage her industry. For all those parts of her own surplus produce which England exchanges for those enumerated commodities, she must get a better price than any

other countries can get for the like parts of theirs, when they exchange them for the same commodities. The manufactures of England, for example, will purchase a greater quantity of the sugar and tobacco of her own colonies, than the like manufacturers of other countries can purchase of that sugar and tobacco. So far, therefore, as the manufactures of England and those of other countries are both to be exchanged for the sugar and tobacco of the English colonies, this superiority of price gives an encouragement to the former, beyond what the latter can in these circumstances enjoy. The exclusive trade of the colonies, therefore, as it diminishes, or, at least, keeps down below what they would otherwise rise to, both the enjoyments and the industry of the countries which do not possess it; so it gives an evident advantage to the countries which do possess it over those other countries.

This advantage, however, will, perhaps, be found to be rather what may be called a relative than an absolute advantage; and to give a superiority to the country which enjoys it, rather by depressing the industry and produce of other countries, than by raising those of that particular country above what they would naturally rise to in the case of a free trade. The tobacco of Maryland and Virginia, for example, by means of the monopoly which England enjoys of it, certainly comes cheaper to England than it can do to France, to whom England commonly sells a considerable part of it. But had France and all other European countries been, at all times, allowed a free trade to Maryland and Virginia, the tobacco of those colonies might, by this time, have come cheaper than it actually does, not only to all those other countries, but likewise to England. The produce of tobacco, in consequence of a market so much more extensive than any which it has hitherto enjoyed, might, and probably would, by this time, have been so much increased as to reduce the profits of a tobacco plantation to their natural level with those of a corn plantation, which, it is supposed, they are still somewhat above. The price of tobacco might, and probably would, by this time, have fallen somewhat lower than it is at present. An equal quantity of the commodities either of England, or of those other countries, might have purchased in Maryland and Virginia a greater quantity of tobacco than it can do at present, and, consequently, have been sold there for so much a better price. So far as that weed, therefore, can, by its cheapness and abundance, increase the enjoyments or augment the industry either of England or of any other country, it would probably, in the case of a free trade, have produced both these effects in somewhat a greater degree than it can do at present. England, indeed, would not in this case have had any advantage over other countries. She might have bought the tobacco of her colonies somewhat cheaper, and, consequently, have sold some of her own commodities somewhat dearer than she actually does: but she could neither have bought the one cheaper nor sold the other dearer than any other country might have done. She might, perhaps, have gained an absolute, but she would certainly have lost a relative advantage.

On the first of the topics here suggested, that the colonies are burdens, on account of the expense of the protection, &c., it has been well remarked 1. That in making up the accounts something must be allowed for the naval force necessary to be kept up in remote parts of the world, even if we had no direct interests in those of this kind. 2. That the colonies themselves, in many instances, contribute materially to their own defence and protection. With Jamaica, Canada, and our East India possessions this is the case: in some instances all the civil and military expense is *bonâ fide*, met by them; in others, as in many of the West India islands, a duty of $4\frac{1}{2}$ per cent. is laid on the commerce of the colony, with this object directly in view. When the charge on the mother country shall be ascertained, making these allowances, what she also draws from them in taxes must be estimated, before the relative advantages or disadvantages to her industry for the possession, can be fairly computed.

In entering upon these more fully, we avail ourselves of an able abstract of the whole question, in a late number of the Quarterly Review. The ties of intercourse between protectors and dependent states, it is suggested, give rise to the formation of multifarious commodities in a European country, to pay for the exotic productions sent into it in return. If these articles equal in the value the expense of the colonies, here is a source of profit and enjoyment, not a burden, created. But on examination of the value of colonial intercourse, compared with that of independent states, it will appear that the exports made to the colonies exclusively originating in their demand, vastly exceed their real expense. Were this demand therefore to cease, so much of the labor of the producers would have to be directed to other objects, or cease also.

To this it may be added, that the very habits and prejudices of a colony, in close intercourse with the mother country, will always cause its thriving classes to imitate her manners, and to introduce the articles of her greatest profit and skill. But could we without the colonies rely on possessing the same extent of production, and consequently power to purchase of them or of other states, still the security and permanence of an intercourse under our control is an important consideration. The certainty of a home trade is acquired. The whole of the produced wealth is the property of natural born subjects. It is not on one side that of foreigners; nor are we exposed to interruptions from caprice or policy, or the occurrence of hostilities between other powers. A foreign state may, by regulations, draw its supplies, even of the staples and manufactures in which this country is confessedly superior, from other sources: and this stability in our relations will repay many sacrifices.

Another object of primary importance, attendant upon a colonial trade, is the employment of seamen. The right to supply and manage a large portion of the conveyance has ever been accounted a source of natural strength and property. Without the possession of colonies it is difficult to say how this can be attained, unless the sources of the produce were independent states, and would forego (what no state possessing

shipping ever did forego) compensating duties and favor shown to its own vessels.

Dependent possessions, again, scattered over all parts of the world, become secure marts from which commerce can be carried on with every quarter: without them, the intercourse with many places, in an imperfectly civilised or often disturbed state, would be precarious and hazardous; and they confer, wherever situated, a local influence, upholding the character and interests of the country. Thus Jamaica and the West India Islands have been the means of our extensive intercourse with South America, amid all the troubles to which that quarter has been subject: and in the Mediterranean, Gibraltar and Malta, although not in themselves productive, become beneficial chains of communication with Barbary, and other parts. Our East India possessions, besides the commerce actually held with them, are the means of conducting an intercourse with every shore of the Indian seas.

'The question, in fine,' says the able paper adverted to, 'is, whether that country is best situated which is secure of a given place where the products of its labor can be exchanged, or that which has to seek throughout the world for permission to exchange them? Whether the colonies are best circumstanced, in seeking all the markets of the continent, or in being sure of the certain great market of this country? Whether it is better on both sides, to be subject to the caprices of nations, as well as the vicissitudes of seasons, or to be dependent only on the latter? Whether to give safety to the exchanges of labor, so far as in us lies, or to commit ourselves to all the chances and windings of other states? Let those who deal with independent countries answer how far their intercourse is secure and stable, and the nature and extent of their vent to be foreseen. Let the traders with Russia speak to the variations, not only arising from seasons but from altered tariffs, which every year brings forth, and tell us, whether at any period, it is possible to

take measures certain to be adapted to the custom-house regulations of that empire, and their effect upon consumption.'

We are then supplied with the following interesting facts respecting the colonial system of our neighbours. 'In 1699 Colbert estimated the number of French vessels engaged in foreign trade at 600. Of these not more than 100 were supposed to be employed in the commerce of the West Indies. At the revolution, France had not more than 1000 vessels engaged in distant voyages, or about 200,000 tons. Far the larger part of this very limited tonnage (compared with the great commerce of France) was owing to her West India colonies; for, from various reasons, her commerce with other parts was carried on in foreign shipping; that with her colonies was wholly her own. The tonnage of her European trade was only 152,000 tons. So entirely did the strength of the French marine appear, at that time, to depend on the colonies, that one of the ministers, M. Arnould, to whom we are indebted for the statements we present, exclaims; 'Quelles ressources a donc la France pour entretenir une force publique maritime? Quels moyens lui restent pour élever, instruire, et multiplier la classe précieuse des matelots? Le commerce de l'Amerique,—ne l'oublions pas, le commerce de l'Amerique.'

The following table will show the rapid progress of the French West India colonies within the last century, and their importance to that country; together with the value of the product re-exported, and of that which was consumed at home. It will be seen that the general export of colonial produce, in the seven years average ending 1733, was 50,630,000 livres. In the five years ending 1788 the average was 93,056,000 livres, being an increase of four-fifths in five years. In 1788 the annual import of sugar into France was about 2,600,000 cwt. She was supposed to export about 1,400,000 cwt.; that is, more than half the quantity imported.

PERIOD.	IMPORTS.	EXPORTS.	HOME CONSUMPTION.	
	Value in Liv. Tour. Average.	Value in Liv. Tour. Average.	Value in Liv. Tour. Average.	
1716 to 1725	£ 11,155,000	6,361,000	4,794,000	Value at the time.
	£ 17,211,000	9,815,000	7,206,000	Value in 1788.
1725 to 1732	£ 16,609,000	14,814,000	1,795,000	Value at the time.
Peace.	£ 18,131,000	16,014,000	2,117,000	Value in 1788.
1733 to 1735	£ 20,631,000	15,028,000	3,603,000	Value at the time.
War.	£ 21,845,000	15,912,000	5,933,000	Value in 1788.
1736 to 1739	£ 35,435,000	20,619,000	14,816,000	Value at the time.
Peace.	£ 37,519,000	21,332,000	15,687,000	Value in 1788.
1740 to 1748	£ 36,918,000	25,152,000	11,766,000	Value at the time.
War.	£ 39,090,000	26,530,000	12,460,000	Value in 1788.
1749 to 1755	£ 65,207,000	35,225,000	29,981,000	Value at the time.
Peace.	£ 69,043,000	37,298,000	31,745,000	Value in 1788.
1756 to 1763	£ 15,463,000	12,196,000	3,267,000	Value at the time.
War.	£ 16,373,000	12,913,000	3,460,000	Value in 1788.
1764 to 1776	£ 111,900,000	37,696,000	74,234,000	Value at the time.
Peace.	£ 116,603,000	39,146,000	77,459,000	Value in 1788.
1777 to 1783	£ 108,710,000	50,630,000	58,080,000	Value in 1788.
War.				
1784 to 1788	£ 193,250,000	93,056,000	100,194,000	Value in 1778.
Peace.				

‘ France, on the late peace, was no sooner re-possessed of colonies than her legislative body proceeded to establish her maritime commerce on a footing the first feature of which is favor to them; in a similar spirit she has granted the highest encouragement to her fisheries: thus a few years have sufficed to re-animate a marine which was nearly extinct, and which might have remained in that listless state, had she permitted those nations already in possession of the navigation of the seas to become her carriers.’

The following statement of the employment of

our shipping, for which we are indebted to the same source, will exhibit the tonnage clearing outwards to the principal colonial possessions, during the year ending the 5th of January, 1821; and will, likewise, furnish a contrast with the shipping engaged in the intercourse with the more important independent states. It will show, too, how large a portion of our foreign intercourse is carried on by the shipping of other countries; and how considerable a share of our navigation owes its existence to the strict colonial system.

	British Tonnage.	Foreign Tonnage.
British North American Colonies	300,695	
British West India Colonies	217,744	
East Indies	76,833	
France	80,361	50,954
United States	44,589	133,516
Holland	53,828	37,222
Germany	107,601	19,680
Russia	111,290	14,995
Sweden and Norway	15,641	51,102

The following is a statement of the official value of exports to the colonies at this period, and will show that they take as much British produce as the greater part of Europe; while again the colonial produce imported for re-exportation, forms a large portion of the exports to Europe.

	British Produce.	Foreign and Colonial.	Total.
British North American Colonies	£1,548,181	£452,852	£2,001,033
British West India Colonies	4,197,975	292,033	4,490,008
East Indies	2,039,507	382,256	2,421,763
France	246,144	734,677	980,821
Holland	1,153,120	1,129,555	2,282,675

Russia	1,630,047	406,016	2,036,063
United States	4,229,767	71,928	4,301,695

COLOPHION, in ancient geography, a town of Ionia, seated on a promontory on the Ægean Sea, and washed by the Hælesus. It was destroyed by Lysimachus, in his war with Antigonus, in order to enlarge Ephesus: but, according to Pausanias, it was rebuilt in the neighbourhood, on a more commodious site. This is one of the cities that laid claim to the honor of giving birth to Homer. Of this town was the poet Antimachus.

COLOPHONEM ADDERE, the addition of a preponderating weight, a proverbial saying, explained by Strabo, who says, that the Colophonian horse generally turned the scales in favor of the side on which they fought.

COLOPHONY, *n. s.* Rosin; from Colophon, a city, whence it came.

Of Venetian turpentine, slowly evaporating about a fourth or fifth part, the remaining substance suffered to cool, would afford me a coherent body, or a fine *colophony*.
Boyle.

Turpentine and oils leave a *colophony*, upon a separation of their thinner oil.

Floyer on the Humours.

COLOQUINTEDA, *n. s.* Lat. *colocynthis*; κολόκυνθις. The fruit of a plant of the same name, brought from the Levant, about the bigness of a large orange, and often called bitter apple. Both the seed and pulp are intolerably bitter. It is a violent purgative, of considerable use in medicine.

COLOQUINTIDA, in botany. See CUCUMIS.

C O L O R S.

COLOUR, *v. a., v. n., & n. s.* } Lat. *coloro*,
 COLOURABLE, *adj.* } *color*. The sub-
 COLOURABLY, *adv.* } stantive has ap-
 COLORED, *part. adj.* } plications which
 COLOURING, *n. s.* } distinguish it
 COLOURIST, *n. s.* } from the verb,
 COLOURLESS, *adj.* } and these we
 must mark. The appearance of bodies to the
 eye only; hue; dye. The freshness or appearance
 of blood in the face. In the plural, a standard;
 an ensign of war.

Colours ne know I non, withouten drede,
 But swiche *colours* as growen in the mede,
 Or elles swiche us men die with or peinte;
Colours of rhetorike ben to me quicnte;
 My spirit feleth not of swich matere.

Chaucer's Canterbury Tales.

Her hair shall be of what *colour* it please God.
Shakspeare.

He at Venice gave
 His body to that pleasant country's earth,
 And his pure soul unto his captain Christ,
 Under whose *colours* he had fought so long.

Id. Richard II.

Against all checks, rebukes, and manners,
 I must advance the *colours* of my love,
 And not retire. *Id. Merry Wives of Windsor.*

When on the east the morning ray,
 Hangs out the *colours* of the day,
 The bee through these known allies hums,
 Beating the dian with its drums. *Marce.*

For though our eyes can nought but *colours* see,
 Yet *colours* give them not their power of sight.

Davies.

he lights of *colours* are more refrangible one than
 another in this order; red, orange, yellow, green,
 blue, indigo, deep violet. *Newton's Optics.*

My cheeks no longer did their *colour* boast,
Dryden.

A sudden horror seized his giddy head,
 And his ears trickled, and his *colour* fled. *Id.*

All in a moment through the gloom were seen
 Ten thousand banners rise into the air
 With orient *colours* waving. *Milton's Paradise Lost.*

Each gaudy bird some slender tribute brings,
 And lends the growing insect proper wings;
 Silks of all *colours* must their aid impart,
 And every fur promote the fisher's art.

Gay's Rural Sports.

It is a vulgar idea of the *colours* of solid bodies,
 when we perceive them to be a red, or blue, or green
 tincture of the surface; but a philosophical idea,
 when we consider the various *colours* to be different
 sensations, excited in us by the refracted rays of light,
 reflected on our eyes in a different manner, according
 to the different size, or shape, or situation of the par-
 ticles of which surfaces are composed. *Watts.*

The verb signifies to mark with some hue or
 dye; to palliate; to excuse; to dress in specious
 colors, or fair appearances belied by the reality;
 to make plausible. In the neuter sense to blush.
 These applications are common to the substan-
 tive, and to all the other branches of the word;
 technically, to color strangers' goods, is when a
 freeman allows a foreigner to enter goods at the
 custom-house in his name, so that the foreigner

pays but single duty, when he ought to pay
 double.

They were glad to lay hold on so *colourable* a mat-
 ter, and to traduce him as an author of suspicious in-
 novation. *Hooker.*

We hope the mercy of God will consider us unto
 some mitigation of our offences; yet had not the sin-
 cerity of our parents so *colourable* expectations.

Brown's Vulgar Errors.

I told him that I would not favour or *colour* in any
 sort his former folly. *Raleigh's Essays.*

The *coloured* are coarser juiced, and therefore not
 so well and equally concocted.

Bacon's Natural History.

The process, howsoever *colourably* awarded, hath
 not hit the very mark whereat it was directed.

Bacon.

They have now a *colourable* pretence to withstand
 innovations, having accepted of other laws and rules
 already. *Spenser.*

Had I sacrificed ecclesiastical government and re-
 venues to their covetousness and ambition, they would
 have found no *colourable* necessity of an army.

King Charles.

He *colours* the falsehood of Æneas by an express
 command from Jupiter to forsake the queen.

Dryden's Æneid.

Titian, Paul Veronese, Van Dyck, and the rest of
 the good *colourists*, have come nearest to nature.

Dryden's Dufresnoy.

The rays, to speak properly, are not *coloured*: in
 them there is nothing else than a certain power and
 disposition to stir up a sensation of this or that *colour*.

Newton's Optics.

Transparent substances, as glass, water, and air,
 when made very thin by being blown into bubbles, or
 otherwise formed into plates, exhibit various colours,
 according to their various thinness; although at a
 greater thickness they appear very clear and *colour-
 less*. *Id.*

Pellucid *colourless* glass or water, by being beaten
 into a powder or froth, do acquire a very intense
 whiteness. *Bentley.*

We have scarce heard of an insurrection that was
 not *coloured* with grievances of the highest kind, or
 countenanced by one or more branches of the legisla-
 ture. *Addison's Freeholder.*

But as the slightest sketch, if justly traced,
 Is by ill *colouring* but the more disgraced;
 So by false learning is good sense defaced. *Pope.*

Flowers fresh in hue, and many in their class,
 Implore the pausing step, and with their eyes
 Dance in the soft breeze in a fairy mass;
 The sweetness of the violet's deep blue eyes,
 Kissed by the breath of heaven, seems *coloured* by its
 skies. *Byron's Childe Harold.*

COLORS, in the Latin and Greek churches,
 are used to distinguish several mysteries and
 feasts celebrated therein. Five colors only are
 regularly admitted, viz. white, green, red, violet,
 and black. The white is for the mysteries of our
 Saviour, the feast of the Virgin, those of the
 angels, saints and confessors; the red is for the
 solemnities of the holy sacrament, the feasts of
 the apostles and martyrs; the green for the time
 between pentecost and advent, and from epi-
 phany to septuagesima; the violet in advent and
 Christmas, in vigils, rogations, &c. and in votive

masses in time of war; lastly, the black is for the dead, and the ceremonies thereto belonging. In the Greek church the use of colors is almost abolished, but red was, in the Greek church, the color for Christmas and the dead, as black among us.

Colors, in heraldry. The only colors in general use are the following :

Colors.		Precious Stones.	Planets.
Red	} termed	Ruby	Mars.
Blue		Sapphire	Jupiter.
Green		Emerald	Venus.
Purple		Amethyst	Mercury.
Black		Diamond	Saturn.
Orange		Hyacinth	Dr. Head.
		Gules	
	Azure		
	Vert		
	Purpure		
	Sable		
	Tenne		

Gules, fig. 1, is expressed by lines perpendicular from top to bottom. Azure, fig. 2, by horizontal lines from side to side. Sable, fig. 3, by horizontal and perpendicular lines crossing each other. Vert, fig. 4, by hatched lines from right to left diagonally. Purpure, fig. 5, by hatched lines from the sinister chief to the dexter base, diagonally; and Tenne, tawny, fig. 6, by diagonal lines from the dexter to the sinister side of the shield, traversed by perpendicular lines.

Fig. 1. Fig. 2. Fig. 3. Fig. 4. Fig. 5. Fig. 6.

Colors, in the military art, are large silk flags fixed on half pikes, and carried by the ensign; whence the purchase of an ensigny is called the purchase of a pair of colors. The size of the colors, in England, should be six feet six inches flying, and six feet deep on the pike, and the length of the pike nine feet ten inches. The cords and tassels of the whole are crimson and gold mixed.

Colors, Camp, a small sort of colors placed on the right and left of the parade of the regiment when in the field: they are eighteen inches square, and of the color of the facing of the regiment, with the number of the regiment upon them.

COLOR-MAKING is the act of preparing the different kinds of colors used in painting, drawing, dyeing, calico-printing, &c. The art of dyeing is sufficiently important to claim our distinct notice; the colors of calico-printing follow; our remarks and directions in this paper are more particularly directed to the preparing of colors used in drawing and painting.

This art is altogether, as we have seen, a branch of chemistry; and one of the most curious, though least understood, parts of it. The principles on which color-making depends differ greatly, however, from those on which the theory of other parts of chemistry is founded; and the practical part being in the hands of those who often find

it their interest to conceal their methods, it happens that there is not only no distinct theory of this art, but few good receipts to be obtained for making any color.

SECT. I.—GENERAL DIVISIONS OF COLORS.

1. The first general division of colors is into opaque and transparent. The former comprehends such colors as, when laid over paper, wood, &c. cover them fully, so as to efface any other painting or stain that might have been there before. The latter includes colors of such a nature as to leave the ground on which they are laid visible through them. Of the first kind are white lead, red lead, vermilion, &c., of the second are the colors used for illuminating maps, &c.

2. A second division is into oil colors and water colors; or such as are appropriated to painting in oil and water. Most of those which are proper for painting in water, are also proper for being used in oil. There is, however, this remarkable difference betwixt colors when mixed with water and with oil, that such as are quite opaque in water will become perfectly transparent in oil. Thus, blue verditer, though exceedingly opaque in water, if ground with oil, seems totally to dissolve, and will become very transparent. The same thing happens to such colors as have for their basis the calx of tin, alabaster, or calcareous earth. The most perfectly opaque colors in oil are such as have lead, mercury, or iron, for their basis: to the latter, however, Prussian blue is an exception; for, though the basis of that color is iron, it proves quite transparent when ground with oil. In water colors, those prepared from metals, Prussian blue alone excepted, are always opaque; from vegetables or animals, transparent. Charcoals, however, whether vegetable or animal, are opaque both in water and oil.

3. Colors are farther divided into simple and compound. The simple are such as require nothing to be superadded, to make a full strong color, without regarding whether they are formed of many or few ingredients. In this view, white lead, red lead, vermilion, calces of iron, &c. are simple colors. The compounds are formed by the union of two or more coloring substances: as blue and yellow united together to form an orange, a white earth or calx mixed with the red color of cochineal or Brasil to form a lake, &c., and thus carmine, lake, rose pink, Dutch pink, English pink, &c. are compound colors.

4. The last and most important division of colors is into true and false. By true colors are meant those which retain their color under every possible variety of circumstances, without fading in the least: the false are such as do not; but either lose their color altogether, or change to some other.

SECT. II.—OF THE CAUSES OF THE FADING OF COLORS.

Colors are chiefly affected by their being exposed to the sun in summer, and to the cold air in winter; but to this there is one exception, viz. white lead; which, when ground with oil, retains its whiteness if exposed to the weather, but degenerates into a brownish or yellow color if kept

close. In water this substance is very apt to lose its color, whether exposed to the air or not. The great desideratum in color-making is to produce such colors as will not fade by exposure to the weather; and, indeed, it is to be regretted, that the most beautiful are in general the least permanent. It may for the most part, however, be expected, that the more simple any color is, the less liable it will be to change upon exposure to the air. The principal difficulty of ascertaining whether a color will fade or not, arises from our ignorance concerning the nature of coloring substances. We may hold it as a rule, however, that whatever change of color is produced in any substance by exposure to the sun and air, that color to which it changes will bid fair for being permanent, and therefore ought to be employed where it can be done.

Of such changes the instances are rare. One is in the purple of the ancients, which assumed its color by exposure to the sun, and consequently was exceedingly permanent. Another is in the solution of silver; which, being mixed with chalk, the precipitate turns to a purplish black where it is exposed to the sun. A third is in solutions of indigo by alkaline substances, which constantly appear green till exposed to the air by spreading them very thin, upon which they become almost instantaneously blue, and continue so ever after.

Sometimes, though still more rarely, a very remarkable change of color happens, upon mixing two vegetable juices together. Almost the only instance of this we have on the authority of Mr. Foster, who says that the inhabitants of Otahete dye their cloth of a crimson color, by mixing together the yellow juice of a small species of fig with the greenish juice of a fern. But the most remarkable alterations of color are effected by different metallic and saline solutions, mixed with certain animal and vegetable substances; and with these the color-maker will be principally conversant.

It is a fact well known in chemistry, that acids mixed with blue vegetable juices turn them red, and alkalis green. It is equally certain, though not so generally known, that acids of all kinds generally tend to heighten red colors, so as to make them approach to the scarlet or true crimson; and alkalis to darken, or make them approach to blue or purple. Mixed with yellow colors, acids also universally tend to brighten the yellow; and alkalis to turn it to an orange, and make it become more dull. But, though this is very generally the case, all acids are not equally powerful in this respect. The nitrous acid is found to heighten the most of any, and the marine acid the least of the mineral ones. The vegetable acids are less powerful than the mineral. Thus, if with a tincture of cochineal in water or spirit of wine, is mixed pure nitrous acid, it will change the color to an orange or flame color, which it will impart to cloth. If the vitriolic acid is used, a full scarlet, inclining to crimson rather than orange, is produced. With marine acid a true crimson color, bordering on purple, is the consequence. Alkalis, both fixed and volatile, change the color to a purple which is brighter with the volatile than the fixed alkalis. It is obvious that, whatever colors are produced by

the mixtures of different substances together, the permanency of these colors can only be in proportion to the ability of such mixtures to resist the weather. Thus, suppose a high scarlet or orange color is produced by means of spirit of nitre, it is plain that, was such a color exposed to the air, it could remain no longer than the spirit of nitre which produced it remained. In proportion, therefore, as the spirit of nitre was exhaled, or otherwise destroyed, it behoved the color to fade, and at last to be totally destroyed; and thus, in proportion to the destructibility of the substances by which colors are produced, will be the disposition of such colors to fade, or the contrary.

Alkalis are in this respect much more destructible than acids, and consequently less proper for the preparation of colors. Of the acids, the nitrous seems most destructible, the vitriolic less so, and the marine least of all. From the extreme fixity of the phosphorine acid and sedative salt, perhaps they might be of service in preserving colors.

SECT. III.—OF THE FORMATION OF OPAQUE COLORS.

As all colors, whether derived from the animal or vegetable kingdom, must be extracted either by pure water or some other liquid menstruum, they cannot be used for the purposes of painting till the coloring substance is united with some earthy or solid matter, capable of giving it a body, as the workmen call it; and, according to the nature of this substance, the color will be transparent or otherwise. This basis ought to be of the most fixed and durable nature; unalterable by the weather, by acids, or by alkalis. It ought also to be of a pure white color, and easily reducible into an impalpable powder. For this reason all earthy substances should be avoided as being acted upon by acids; and, therefore, if any of these were added to heighten the color, they would be destroyed, and their effect totally lost. Precipitates of lead, bismuth, &c., though exceedingly fine and white, ought also to be avoided, as being apt to turn black by exposure.

Alumina, in many instances, answers very well; but the substance to be chiefly preferred to all others, is calx of tin, prepared either by fire or the nitrous acid. This is so exceedingly refractory as not only to be unalterable by alkalis, acids, or the sun and weather, but even by the focus of a very large burning mirror. It is besides white as snow, and capable of being reduced to an extreme degree of fineness, inasmuch that it is made use of for polishing metal-line speculums. For these reasons, it is the most proper basis for all fine colors. For coarse ones, the white precipitate of lead will answer very well. It has a very strong body, i. e. it is very opaque, and will cover well; may be easily ground fine, and is much less apt to turn black than white lead; it is besides very cheap, and may be prepared at the small expense of 3*d.* per pound.

The general method of extracting colors from any vegetable or animal substance, and fixing them on a proper basis, may thus be very easily

understood. For this purpose, a quantity of calx of tin is to be procured, in proportion to the quantity of color desired. This must be well rubbed in a glass mortar, with a little of the substance designed for brightening the color, as alum, cream of tartar, spirit of nitre, &c. after which it must be dried, and left for some time, that the union between the two substances may be as perfect as possible. If the color is to be a very fine one, suppose from cochineal, the coloring matter must be extracted with spirit of wine without heat. When the spirit is sufficiently impregnated, it must be poured by little and little upon the calx, rubbing it constantly, to distribute the color equally through all parts of the calx. The spirit soon operates, and leaves the calx colored with the cochineal. More of the tincture is then to be poured on, rubbing the mixture constantly as before; and thus, with proper management, may very beautiful colors, not inferior to the best carmine, be prepared at a moderate expense. In like manner by substituting, for the cochineal, Brasil wood, turmeric, logwood, &c. different kinds of red, yellow, and purple, will be produced. For the coarser colors aqueous decoctions are to be used in a similar manner; only as these are much longer evaporating than the spirit of wine, very little must be poured on at a time, and the colors ought to be made in large quantity, on account of the tediousness of the process.

We have hitherto mentioned only the effects of the pure and simple salts, viz. acids and alkalis, on different colors; but by combining the acids with alkalis, earths, or metals, these effects may be varied almost ad infinitum; nor is there any rule yet laid down by which we can judge a priori of the changes of color that will happen on the admixture of this or that particular salt with any coloring substance. In general, the perfect neutral salts act weakly; the imperfect, especially those formed from metals, much more powerfully. Alum and sal ammoniac considerably heighten the color of cochineal, Brasil, turmeric, fustic, madder, logwood, &c. The same thing is done, though in a less degree, by common salt, Glauber's salt, saltpetre, and many other neutrals.

Solutions of iron in all the acids strike a black with each of the above-mentioned substance; and likewise with sumach, galls, and other astringents. Solutions of lead universally debase red colors to a dull purple. Solutions of copper change the purple color of logwood to a pretty good blue; and, in general, solutions of this metal are friendly to blue colors. The effects of solutions of gold, silver, and mercury, are not so well known; they seem to produce dark colors of no great beauty. The most powerful solution, however, with regard to a great number of colors, is that of tin, made in aqua regia. Hence we may see the fallacy of Mr. Delaval's hypothesis concerning colors, that the least refrangible ones are produced by the most dense metals: for tin which has the least density of any metal, has yet, in a state of solution, the most extraordinary effects upon the least refrangible colors as well as those that are most so. The color of cochineal is changed by it into the most beautiful scarlet; a similar change is made

upon the coloring matter of gum-lac. Brasil wood is made to yield a fine purple crimson; logwood, a beautiful dark purple; turmeric, fustic, weld, and all yellow-coloring woods and flowers, are made to communicate colors far more beautiful than can be got from them by any other method. The blue colors of the flowers of violet, eye-bright, iris, &c. are heightened so as to equal, if not excel, the blue produced by a solution of copper in copper in volatile alkali. In short this solution seems to be of much more extensive use in color-making, when properly applied, than anything hitherto thought of. It is not, however, universally serviceable. The color of madder it totally destroys, and likewise that of safflower, changing them both to a dull orange. It likewise spoils the color of ardcil; and, what is very remarkable, the fine red color of tincture of roses made with oil of vitriol is changed by it to a dirty green.

SECT. IV.—OF THE CHOICE OF COLORING MATERIALS.

One of the most important considerations in color-making is to choose such materials as produce the most durable colors. If these can be procured, an ordinary color from them is to be preferred to a bright one from those which fade sooner. In what the difference consists between the colors that fade and those which do not, is not known with any degree of certainty. From some appearances it would seem, that those substances which are most remarkable for keeping their color, contain a viscous glutinous matter, so combined with a resinous one as to be soluble in water and spirit of wine. The most durable red color is prepared from gum-lac. This is very strongly resinous, though, at the same time, so far glutinous, that the coloring matter can be extracted from it by water. Next to gum-lac are madder roots and cochineal. The madder is an exceedingly penetrating substance, insomuch that, when given to animals along with their food, it tinges their bones of a deep red color. Its coloring matter is soluble both in water and spirit of wine. Along with the pure red, however, there is in madder a kind of viscous astringent substance, of a dark brown color, which seems to give the durability to the whole. The coloring matter of cochineal, though soluble both in water and spirit of wine, is very tenacious and mucilaginous, in which it bears some resemblance to the purpura of the ancients, which kept its color exceedingly well.

Where the colors are fugitive, the tinging substance seems to be too resinous or too mucilaginous. Thus the colors of Brasil, turmeric, &c. are very resinous, especially the latter; insomuch that the coloring matter of turmeric can scarcely be extracted by water. Both these are perishable, though beautiful colors; and much more the red, purple, and blue flowers, commonly to be met with. These seem to be entirely mucilaginous without the least quantity of resinous matter. The yellow flowers are different, and in general keep their color pretty well. Perhaps fugitive colors might be rendered durable, by adding a proportion of gum or resin. A process has been given by Mr. Hellet for imparting durability to

the color of Brasil. It consists only in letting decoctions of the wood stand for some time in wooden casks till they grow stale and ropy. Pieces of woollen cloth, dyed in the liquor, acquired a color so durable that they were not in the least altered by exposure to the air during four months in the winter season. Whether this change in the durability of the color was effected by the ropiness following the fermentation, must be decided by future experiments.

SECT. V.—OF THE PIGMENTS COMMONLY SOLD IN THE COLOR SHOPS.

The preceding sections contain the substance of all that can as yet be depended upon for establishing a general theory of color-making. We now proceed to give an account of the different pigments generally to be found in the color shops.

1. **BLACK.**—These are the lamp-black, ivory-black, blue-black, and Indian-black. The first is the finest of what are called the soot-blacks, and is more used than any other. Its preparation is described in the Swedish Transactions for 1754, as a process dependent on the making of common resin: the impure resinous juice, collected from incisions made in pine and fir-trees, is boiled down with a little water, and strained whilst hot through a bag: the dregs and pieces of bark left in the strainer are burnt in a low oven, from which the smoke is conveyed through a long passage into a square chamber, having an opening on the top on which is a large sack made of thin woollen stuff: the soot or lamp-black, concretes partly in the chamber, from whence it is swept out once in two or three days, and partly in the sack, which is now and then gently struck upon, both for shaking down the soot, and for clearing the interstices betwixt the threads, so as to procure a sufficient draught of air through it. In this manner lamp-black is prepared at the turpentine houses in England, from the dregs and refuse of the resinous matters which are there manufactured. Dr. Lewis has some curious observations on this subject. The soot, says he, arising in common chimneys, from the more oily or resinous woods, as fir and pine, is observed to contain more dissoluble matter than that from the other woods; and this dissoluble matter appears, in the former, to be more of an oily or resinous nature than the latter; spirit of wine extracting it most powerfully from the one, and water from the other. The oiliness and solubility of the soot seeming therefore to depend on those of the subject it is made from, it has been thought that lamp-black must possess these qualities in a greater degree than any kind of common soot. Nevertheless, on examining several parcels of lamp-black, procured from different shops, I could not find that it gave any tincture at all, either to spirit or to water. Suspecting some mistake or sophistication, or that the lamp-black had been burnt or charred, as it is to fit it for some particular uses, I prepared myself some soot from linseed oil, by hanging a large copper pan over the flame of a lamp to receive its smoke. In this manner the more curious artists prepare lamp-black for the nicer purposes; and from this collection of it from the flame of a lamp, the pigment probably received its name.

The soot so prepared gave no tincture either to water or spirits, any more than the common lamp-black of the shops. I tried different kinds of oily and resinous bodies with the same event; even the soots obtained from fish oils and tallow did not appear to differ from those of the vegetable oils and resins. They were all of a finer color than the lamp-black commonly sold.

Soot was also collected in like manner from fir, and other woods, by burning small pieces of them slowly under a copper pan. All the soots were of a deeper black color than those obtained from the same kinds of woods in a common chimney; and very little, if at all, inferior to those of the oils: they gave only a just discernible tincture to water and spirit, while the soots of the chimney imparted a strong deep one to both. The soot of mineral bitumens, in this close way of burning, appears to be of the same qualities with those of woods, oils, and resins: in some parts of Germany, great quantities of good lamp-black are prepared from a kind of pit-coal. It appears, therefore, that the differences of soots do not depend altogether on the qualities of the subjects, but in a great measure on the manner in which the subject is burnt, or the soot caught. The soots produced in common chimneys, from different kinds of wood, resinous and not resinous, dry and green, do not differ near so much from one another, as those which are produced from one kind of wood in a common chimney, and in the confined way of burning above-mentioned.

Ivory black is prepared from ivory or bones burnt in a close vessel. This, when finely ground, forms a more beautiful and deeper color than lamp-black; but, in the common methods of manufacturing, it is so much adulterated with charcoal dust, and so grossly levigated, as to be unfit for use. An opaque deep black, for water color, is made by grinding ivory black with gum-water, or with the liquor which settles from the whites of eggs after they have been suffered to stand a little. Some use gum-water and the whites of eggs together, and say, that a small addition of the latter makes the mixture flow more freely from the pencil, and improves its glossiness. It may be observed, however, that though ivory-black makes the deepest color in water as well as in oil painting, yet it is not on this account always to be preferred to other black pigments. A deep jet black color is seldom wanted in painting; and in the lighter shades, whether obtained by diluting the black with white bodies, or by applying it thin on a white ground, the particular beauty of the ivory-black is in a great measure lost.

Blue black is said to be prepared from the burnt stalks and tendrils of the vine. These, however, the color-makers seldom give themselves the trouble of procuring, but substitute in its place a mixture of ivory-black and common blue used for clothes.

Indian ink is an excellent black for water-colors. It has been discovered by Dr. Lewis to consist of a mixture of lamp-black and common glue. Ivory-black, or charcoal, he found to answer equally well, provided they were levigated to a sufficient degree of fineness, which indeed requires no small trouble.

2. **WHITE.**—The white colors commonly to be met with are, white-flake, white-lead, calcined hartshorn, pearl-white, Spanish-white, egg-shell white, and magistry of bismuth. The flake-white and white-lead are properly the same, though the preparation of the former is kept a secret. These are the only whites that can be used in oil, all the rest being transparent unless they are laid on with water. Calcined hartshorn is the most useful of the earthy whites, as being the least alkaline. Spanish white is only finely prepared chalk. Pearl white is made from oyster-shells; and egg-shell white from the shells of eggs. All these, by their attraction for acids, must necessarily destroy such colors as have any acid or metallic salt in their composition. The magistry of bismuth is apt to turn black, as are also flake-white and white-lead, when used in water. The white precipitate of lead is greatly superior as a water-color, to all these; being perfectly free of any alkaline quality, and not apt to lose its own color, or to injure that of other substances.

3. **RED.**—The red colors used in painting are of two sorts; viz. those which incline to the purples and such as are of a full scarlet and tend rather to the orange. The first are carmine, lake, rose-pink, red-ochre, and venetian-red. The second are vermilion, red-lead, scarlet-ochre, common Indian-red, Spanish-brown, and terra di Sienna, burnt. The preparations of carmine and lake, we have noticed in section III. Receipts have been delivered with the greatest confidence for making these fine colors; but all of them must necessarily prove ineffectual, because an earthy basis is recommended for striking the color upon: from the principles of chemistry, we are certain, that if aqua-fortis, or solution of tin, is made use of for brightening a color made with any earthy basis, it must infallibly be destroyed by that basis, by reason of its alkaline quality. Carmine is the brightest and most beautiful red color known; the best comes from France. Lake differs from it in being capable of mixture with oil; which carmine is not, unless with great difficulty. The former is also much more inclined to purple than carmine. This last quality, however, is reckoned a defect; and, accordingly, the more that lake approaches to the scarlet or true crimson, the more it is valued. On dropping solution of tin into an aqueous tincture of Brasil wood, a beautiful precipitate falls, of a purplish crimson color. This may be very well substituted in place of the dearer lakes on many occasions.

Rose pink is a very beautiful color, inclining more to the purple than scarlet. It seems to be made of chalk, colored with a decoction of Brasil wood, heightened by an alkaline salt; for which reason it is exceedingly perishable, and but little esteemed. The color might be made much more durable, as well as better, by employing for a basis the white precipitate of lead, and brightening it with solution of tin.

Red ochre and Venetian red differ in nothing from the colcothar of vitriol well calcined. The calces of iron may be made to appear either purplish, or inclining to the scarlet, according to the manner in which the calcination is performed.

If the matter is perfectly deprived of its phlogiston, and subjected to an intense fire, it always turns out red: but the mixture of a small quantity of inflammable matter gives it a purplish cast. Hence various paints are sold under different names, which yet differ from each other only in the slight circumstance above-mentioned: and such are the scarlet-ochre, Spanish-brown, and terra di Sienna burnt. It is remarkable, that the calces of iron never show their color till they become cold. Colcothar of vitriol, while hot, always appears of a very dark dusky purple.

Vermilion, the best red used in oil painting, does not answer well in water; minium or red-lead is rather an orange; and, like other preparations of lead, is in some cases apt to turn black.

4. **ORANGE.**—The only true orange-colored paints are red orpiment and orange lake. The first is a sublimate formed of arsenic and sulphur: the other may be prepared from turmeric infused in spirit of wine, having its color struck upon calx of tin, and brightened by a solution of that metal. All the shades of orange, however, may be extemporaneously prepared by mixing red and yellow colors together, in due proportions.

5. **YELLOW.**—The yellow paints most commonly used are, king's-yellow, Naples'-yellow, Dutch-pink, English pink, massicot, common orpiment, yellow-ochre, and terra di Sienna unburnt.

Kings' Yellow is evidently an arsenical preparation. Its color is exceedingly beautiful, but apt to fade; on which account, and its great price, it is seldom used.

Naples' yellow was for a long time thought to be a preparation of arsenic, but is now discovered to have lead for its basis. It is, therefore, apt to turn black and lose its color, which makes it the less valuable. It is used in preference to king's yellow, on account of its inferiority in price, though it is particularly liable to be spoiled by iron when moist; and therefore should never be touched by that metal unless previously ground in oil.

Dutch pink is said to be prepared by striking the colors of yellow berries upon finely levigated chalk. But of this there is great reason to doubt; the basis of Dutch-pink seems much more hard and gritty than chalk, and its color more durable than those struck upon that earth usually are. Very good yellow may be prepared with the white precipitate of lead, by using either yellow berries, fustic, or any other substance capable of yielding that color. English pink is paler than the Dutch, and keeps its color much worse.

Massicot is not apt to change, but the color is so dull that it is seldom used either in oil or water.

Common orpiment is a pretty bright greenish yellow. Its nauseous smell is greatly increased by grinding in oil; nor does it keep its color for any length of time. That kind least inclined to green is to be preferred for painting. See the difference between it and realgar, and the method of preparing them, under CHEMISTRY.

Yellow ochre, and terra di Sienna are ferru-

ginous earths, capable of becoming red by calcination. Green vitriol precipitated by lime may be advantageously substituted for either of them.

Turbith mineral is little used in painting, though its fine yellow color seems greatly to recommend it. It is in all probability very durable; and should seem therefore worthy of a preference either to king's or Naples-yellow.

Gamboge can only be used in water, and is the most common yellow made use of for coloring maps, &c. though it is neither quite transparent nor very durable.

6. GREEN.—The only simple green color that has a tolerable degree of brightness is verdigris, or preparations of it. See CHEMISTRY, INDEX. This however, though a very beautiful color, is far from being durable. It is improved in color, though not in durability, by dissolution and crystallisation in distilled vinegar; in which state it is called distilled verdigris. A more durable water-color is made by dissolving the verdigris in cream of tartar, or rather the pure tartareous acid; but in oil this is found to be equally fugitive with the verdigris itself.

Compound greens are either made of Prussian or some other blue, mixed with yellow; but, in whatever way these colors can be compounded, the beauty of the green produced is greatly inferior to distilled, or even common verdigris. The tartareous solution of verdigris, mixed with a little gamboge, is the best transparent green water-color we have had an opportunity of trying; and a mixture of Prussian blue and turbith mineral is probably the best opaque one.

Sap green is a simple color, but exceedingly inferior to distilled verdigris, or even to the tartareous solution of verdigris, with gamboge. It is prepared from the juice of unripe buckthorn berries evaporated to the consistence of a gum. Its green color is greatly inclined to yellow.

A kind of compound green has been sometimes used, called Prussian green, which consists only of Prussian-blue and yellow-ochre. It has no beauty, nor is it durable. It is prepared as Prussian-blue, only not pouring on any spirit of salt to dissolve the ochreous sediment which falls at the same time.

Another green is also sometimes used, called terra verte. It is a native earth, probably impregnated with copper, of a bluish-green color, of that taint called sea-green. It is gritty, and therefore must be well levigated before it is used. Its color is durable, but not very bright.

7. BLUE.—The blue colors are ultra marine, Prussian blue, verditer, smalt, bice, and indigo. Of all these, ultramarine is the finest, but its great price hinders its being much used. It is a preparation from lapis lazuli; is an exceedingly bright color, and never fades with whatever substance it is mixed. It is now, however, in a great measure superseded by Prussian blue. To the disadvantage of painting in general; as Prussian blue, though very beautiful, is far from being durable. Prussian blue is of the best quality when it is deep, bright, and not inclined to purple. It ought to be tried by mixture with white lead, as the brightness of the color will appear much more when diluted, than when concentrated in lumps.

The preparation of blue verditer is kept a secret, and the best chemists have been puzzled to find out the method. The color is exceedingly bright, and has a considerable tinge of green. The following is a method of preparing a color equally beautiful, and agreeing in all respects with what is sold in the shops, except that of effervescing with acid:—Dissolve copper in strong caustic alkali, until the liquid has assumed a very deep blue color; and the deeper this color is, the finer will be the verditer. When the menstruum has dissolved as much of the metal as it can take up, it is to be poured out into a broad and well glazed earthen pan, held over a very gentle fire; and, from the moment it is put on, the liquor is to be continually agitated with a wooden spatula, so that the liquor may be heated as equally as possible. The whole secret consists in properly regulating the degree of heat; for, if it exceed the due proportion ever so little, the verditer will turn out a dirty green. The proper degree is about 90° of Fahrenheit's thermometer. In this gentle heat the alkali slowly evaporates; and, in proportion to its doing so, the verditer falls to the bottom. After it is once formed, freed from the alkaline liquor, and dried, it can bear the affusion of boiling water without the least injury. Dr. Priestley observes, that solution of copper in volatile alkali affords a blue precipitate by heat, but without mentioning the requisites for its success. In making this preparation, it is necessary to dissolve copper in its metallic state; for the solution of any calyx will not yield a blue but a green color. This color is durable in water, but dissolves in oil, and has then all the inconveniences of verdigris above mentioned.

Smalt is a glass colored with zaffre, a preparation from cobalt. It is commonly so grossly powdered that it cannot be used in painting, and its texture is so hard, that it cannot easily be levigated. Its color is exceedingly bright and durable; so that when finely levigated it is used instead of ultramarine. The most proper materials for levigating this substance seem to be the plates of M. Reaumur's porcelain recommended by Dr. Lewis.

Bice. For the preparation and qualities of bice, see ARMENUS and BICE.

Indigo is but little used in painting either in oil or water, on account of the dulness of the color. It requires no other preparation than being washed over. Its goodness is known by the darkness and brightness of the color. See INDIGO.

8. PURPLE.—The only simple color of this kind used at present is colcothar of vitriol. A beautiful purple lake may be prepared from logwood by solution of tin; but this method of preparing colors is very little known as yet.

9. BROWN.—The brown colors are bistre, brown ochre, Cologne earth, umbre, and brown pink.

Under the article BISTRE is given a process for making that color, by infusing soot in water, pouring off the tincture, and then evaporating it to an extract; but Dr. Lewis is of opinion with Mr. Landois in the French Encyclopedie, that the foot is either boiled in water, or ground with a little liquor of some kind into a smooth paste.

it is then diluted with more water, and after standing for about half an hour till the grosser substance of the foot has settled, the liquor is poured off into another vessel, and set by for some days, that the finer parts may fall to the bottom, and this fine matter is the bistré. This is a very useful color in water, being exceedingly fine, durable, and not apt to spoil any other colors with which it is mixed.

Brown pink is said to consist of chalk tinged with the coloring matter of fustic, heightened by fixed alkaline salts. It is therefore very perishable, and is seldom used. The other browns are a kind of ochreous earths; for a description of which, see their proper articles.

SECT. VI.—OF THE ATTEMPTS MADE TO PRODUCE LAKES OF ALL COLORS FROM VEGETABLES.

We shall conclude with noticing some attempts that have been made to produce all the different colors from vegetables, after the manner of lakes; which, though the methods hitherto tried have for the most part failed of success, may perhaps lead to future and more successful exertions. From infusions of astringent vegetables, mixed with green vitriol, is produced a deep black liquor of very extensive use in dyeing. See *DYEING*. The substances which produce the deepest blacks are galls and logwood. When a decoction or infusion of the galls is dropped into a solution of the vitriol largely diluted with water, the first drops produce bluish or purplish-red clouds, which, soon mingling with the liquor, turn it uniformly of their color.

This difference in the color seems to depend on the quality of the water. With distilled water, or the common spring waters, the mixture is always blue. If we previously dissolve in the water the most minute quantity of any alkaline salt, too small to be discovered by any of the common means by which waters are usually tried, or if the water is the least putrid, the color of the mixture proves purple or reddish. Rain water, caught as it falls from the clouds in an open field, in clean glass vessels, gives a blue; but such as is collected from the tops of houses grows purple, with the mixture of vitriol and galls: from whence it may be presumed, that this last has contracted a putrid tendency, or received an alkaline impregnation, though so slight as not to be sensible by other ways of trial. Both the purple and blue liquors, on adding more of the astringent infusion, deepen to a black, more or less intense, according to the nature of dilution: if the mixture prove of a deep opaque blackness, it again becomes bluish or purplish, when further diluted. If suffered to stand in this diluted state for two or three days, the coloring matter settles to the bottom in form of a fine black mud, which, by slightly shaking the vessel, is diffused again through the liquor, and tinges it of its former color. When the mixture is of a full blackness, this separation does not happen, or in a far less degree; for though a part of the black matter precipitates in standing, yet so much remains dissolved, that the liquor continues black. This suspension of the coloring substance, in the black liquid, may be attributed in part to the gunny matter of the

astringent infusion increasing the consistence of the watery fluid; for the separation is retarded in the diluted mixture by a small addition of gum-arabic. If the mixture, either in its black or diluted state, is poured into a filter, the liquor passes through colored: only a part of the black matter remaining on the filter. The filtered liquor, on standing for some time, becomes turbid and full of fine black flakes; being freed from these, by a second filtration, it again puts on the same appearance; and thus repeatedly till all the coloring parts are separated, and the liquor has become colorless.

Dr. Lewis, from whose Philosophical Commerce of Arts this account is taken, informs us that this coloring matter, when separated from the liquor and dried, appeared of a deep black, which did not seem to have suffered any change from the air by exposure for upwards of four months. Made red-hot, it glowed and burned, but did not flame, and became a rusty-brown powder, which was readily attracted by a magnetic bar; though in its black state the magnet had no action upon it. The vitriolic acid, diluted with water, and digested on the black powder, dissolved the greatest part of it, leaving only a very small quantity of whitish matter. Solution of pure fixed alkaline salt dissolved very little of it: the liquor received a reddish brown color, and the powder became blackish brown. This residuum was attracted by the magnet after being red hot, though not before: the alkaline tincture passed through a filter, and mixed with a solution of green vitriol, struck a deep brownish black color, nearly the same with that which results from mixing with the vitriolic solution, an alkaline tincture of galls. It has also been attempted to produce black from a combination of other colors, as green may be produced from a mixture of blue and yellow. M. le Blon, in his *Harmony of Colors*, gives a method of forming black, by mixing together the three colors called primitive, viz. blue, red, and yellow; and M. Castel, in his *Optique des Couleurs*, published in 1740, says that this compound black has an advantage in painting, above the simple ones, of answering better for the darkening of other colors. Thus, if blue, by the addition of black, is to be darkened into the color called blue black, the simple blacks, according to him, if used in sufficient quantity to produce the requisite deepness, conceal the blue, while the compound blacks leave it distinguishable.

Le Blon does not mention the proportions of the three colors necessary for producing black. Castel directs fifteen parts of blue, five of red, and three of yellow; but takes notice, that these proportions are rather speculative than practically just, and that the eye only can be the true judge; our colors being all very imperfect, and our pigments or other bodies of one denomination or color being very unequal in their degree of intensity. He observes, that the pigments should all be of the deepest and darkest kind; and that, instead of taking one pigment for each color, it is better to take as many as can be got; for the greater discord there is of heterogeneous and discordant drugs, the more true and beautiful, he

says, will the black be, and the more capable of uniting with all other colors, without suppressing them, and even without making them tawney.

Dr. Lewis, by mixing different blue, red, and yellow colors, has not been able to produce a perfect black; but has often obtained from them very dark colors, such as may be called brown-blacks or gray-blacks; such as we commonly see in the dark part of paintings, and such as the charcoal and soot blacks appear when diluted a little. The ingredients being of a dark deep color is a very necessary condition; for bright blues, bright reds, and bright yellows mixed in such a proportion that neither color prevailed produced only a gray. In effect, all compositions of this kind, physically considered, can be no other than grays, or some of the intermediate tints between whiteness and darkness; and all these grays will be so much the lighter or darker as the component colors of themselves are bright or dark. To extract the coloring matter from the different kinds of vegetables of all colors, would certainly be a very valuable acquisition, could the colors so procured be made durable. On this subject nothing has appeared more satisfactory than what is delivered by Dr. Lewis in his notes on Neuman's Chemistry. His observations are curious, though they do not promise much success, with regard to fixing these vegetable colors. 'Among the infinite variety of colors, (says he), which glow in the flowers of plants, there are very few which have any durability, or whose fugitive beauty can be arrested by art, so as to be applied to any valuable purposes. The only permanent ones are the yellow, the red, the blue; and all the intermediate shades of purple, crimson, violet, &c. are extremely perishable. Many of these flowers lose their colors on being barely dried; especially if they are dried slowly, as has been usually directed, in a shady, and not warm place. The colors of all of them perish on keeping even in the closest vessels. The more hastily they are dried, and the more perfectly they are secured from the air, the longer they retain their beauty. The coloring matter extracted and applied on other bodies is still more perishable: oftentimes it is changed or destroyed in the hands of the operator. The color of many blue flowers is extracted by infusion in water; but there are some from which water gains only reddish or purplish blue. Of those that have been tried there is not one which gives any blue tincture to spirituous liquors: some give no color at all, and some a reddish one. The juice pressed out from the fresh flowers is for the most part blue. The blue juices and infusions are changed red by all acids. The marine acid seems to strike the most florid red. The flowers themselves, macerated in acid liquors, impart also a deep red tincture. Alkalis, both fixed and volatile, and lime water, change them to a green. Those infusions of the juices which have nothing of the native color of the flowers, suffer the same changes from the addition of acid and alkaline liquors: even when the flowers have been kept till their color is lost, infusions made from them acquire still a red color from the one, and a green from the other, though in a less degree than when

the flowers were fresh. The red color produced by acids is scarcely more durable than the original blue: applied upon other bodies, and exposed to the air, it gradually degenerates into a faintish purple, and at length disappears, leaving hardly any stain behind. The green produced by alkalis changes to a yellow, which does not fade so soon. The green, by lime water, is more permanent and more beautiful: green lakes, prepared from these flowers by lime-water, have been used as pigments by the painter. The flowers of cyanus (the common blue-bottle) have been greatly recommended, as affording elegant and durable blue pigments; but I never have been able to extract from them any blue color at all. Infusions of them in watery, spirituous, and oily liquors, are all, more or less, of a reddish cast, without any tendency to blue. Alum, which is said to heighten and preserve their blue color, changes it, like that of other blue flowers, to a purplish red; acids to a deep red; alkalis and lime-water to a green; solutions of tin added to the watery infusion, turns it to a fine crimson; on standing, a beautiful red fecula subsides, but it loses all its color by the time it is dry. The watery infusion, inspissated to the consistence of an extract, appears of a dark reddish-brown; an extract made with rectified spirits is of a purplish color. The color of both extracts spread thin and exposed to the air quickly fades. Red flowers readily communicate their own red color to watery menstrua: among those that have been tried there is not one exception. Those of a full red color give to rectified spirit also a deep red tincture, brighter, though somewhat paler, than the watery infusion: but the lighter red flowers, and those which have a tendency to purplish, impart very little color to spirit, and seem to partake more of the nature of the blue flowers than of the pure red. Infusions of red flowers are supposed to be heightened by acids, and turned green by alkalis, like those of the blue; but this is far from being universal. Among those I have examined, the rose colors and purplish reds were changed nearly in the same manner as the blues; but the full deep reds were not. The deep infusion of red poppies is changed by alkalis, not to a green but to a dusky purple. The colors of yellow flowers, whether pale or deep, are in general durable. Many of them are as much so, perhaps, as any of the native colors of vegetables. The color is extracted both by water and by spirit. The watery infusions are the deepest. Neither alkalis nor acids alter the species of the color, though both of them vary its shade; acids rendering it paler, and alkalis deeper: alum likewise considerably heightens it, though not so much as alkalis. An infusion of the flowers, made in alkaline lee, precipitated by alum, gives a durable yellow lake. In some of the deep reddish-yellow, or orange-colored flowers, the yellow matter seems to be of the same kind with that of the pure yellow flowers, but the red to be of a different kind from the pure red ones; watery menstrua take up only the yellow, and leave the red, which may afterwards be extracted by rectified spirit of wine, or by water acuted by fixed alkaline salt. Such particularly are the saffron-colored flowers of

Carthamus. These, after the yellow matter has been extracted by water, are said to give a red tincture to lee; from which, on standing at rest for some time, a deep bright red fecula subsides; called, from one of the names of the plant which produces it, *saf-flower*; and, from the countries whence it is commonly brought to us, Spanish red, and China lake. This pigment impregnates spirit of wine with a beautiful red tincture, but communicates no color to water. I have endeavoured to separate, by the same treatment, the red matter of some of the other reddish yellow flowers, as those of garden marigold, but without success. Plain water extracted a yellow color, and alkaline lee extracted afterwards only a paler yellow: though the digestions were continued till the flowers had lost their color, the tinctures were no other than yellow, and not so deep as those obtained from the pure yellow flowers. The little yellow flosculi, which in some kinds of flowers are collected into a compact round disc, as in the daisy and corn-marigold, agree, so far as they have been examined, with the expanding yellow petals. Their color is affected in the same manner by acids, by alkalis, and by alum; and equally extracted by water and by spirit. But the yellow farina, or fine dust lodged on the tips of the stamina of flowers, appears to be of a different kind. It gives a fine bright yellow to spirit, and a duller yellow to water; the undissolved part proving in both cases of a dull yellowish-white. Both the watery and spirituous tinctures were heightened by alkaline liquors, turned red by acids, and again to a deep yellow on adding more of the alkali: I know no other vegetable yellow that is turned to red by acids.

White flowers are by no means destitute of coloring matter. Alkaline lixivium extract from some of them a green tincture, and change their colorless expressed juices to the same color; but I have not observed that they are turned red by acids. The flowers of the common wild convolvulus or bind-weed, which in all their parts are white, give a deep yellow or orange tincture to plain water; which, like the tincture of flowers that are naturally of that color, is rendered paler by acids, heightened a little by alum, and more considerably by alkaline salts. The vapors of the volatile vitriolic acid, or of burning sulphur, which whiten or destroy the color of the colored flowers, make no change in the white. The red juices of fruits, as currants, mulberries, elderberries, morello, and black cherries, &c. gently inspissated to dryness, dissolve again almost totally in water, and appear nearly of the same red color as at first. Rectified spirit extracts the tinging particles, leaving a considerable portion of mucilaginous matter undissolved; and hence the spirituous tincture proves of a brighter color than the watery. The red solutions, and the juices themselves, are sometimes made dull, and sometimes more florid, by acids, and generally turned purplish by alkalis. The colors of these juices are, for the most part, perishable. They resist, indeed, the power of fermentation, and continue almost unchanged, after the liquor has been converted into wine; but when the juice is spread thin upon other bodies, exsiccated, and exposed to the air, the color quickly alters and decays;

the bright lively red changes the soonest; the dark dull red stain from the juice of the black-cherry, is of considerable durability. The fruit of the American opuntia or prickly pear, the plant upon which the cochineal insect is produced, is perhaps an exception. This bright red fruit, according to Labat, gives a beautiful red dye. Some experiments, however, made upon the juice of that fruit, as brought into England, did not promise to be of any great advantage. The ripe berries of buckthorn stain paper of a green color. From these is prepared the substance called sap-green, a pigment sufficiently durable, readily soluble in water, but not miscible in oil. It is said that the berry of the *heliotropium tricoecum*, which grows wild about Montpellier, stains paper of a green color, and that this green turns presently to a blue; that the common blue paper receives its color from this juice; and that the red rags, called turnsole, employed for coloring wines and other liquors, are tintured by the same juices, turned red by acids. According to M. Nissolle, of the French Academy of Sciences, the coloring juice is obtained not from the berries, but from the tops of the plant gathered in August, ground in mills, and then committed to the press. The juice is exposed to the sun about an hour, the rags dipt in it, dried in the sun, moistened by the vapor which arises during the slaking of quicklime with urine, then dried again in the sun, and dipped again in the juice. The Dutch and others are said to prepare turnsole rags, and turnsole in the mass, from different ingredients, among which argil is a principal one. In some plants, peony for instance, the seeds, at a certain point of maturity, are covered with a fine shining red membrane. The pellicles of the seeds of a certain American tree afford the red masses brought into Europe under the names of *annotta*, *orlean*, and *rancou*. See ANOTTA. Mr. Pott, in the Berlin Memoirs, for the year 1752, mentions a very extraordinary property of this concrete. 'With vitriolic acid it produces a blue color of extreme beauty; but with this capital defect, that all salts and liquors and even common water, destroy it.' The specimen of *annotta*, which I examined, was not sensibly acted upon by spirit of vitriol; it received no change in its own color, and communicated none to the liquor. Nor did any visible change ensue upon dropping the acid into tinctures of *annotta* made in water or in spirit. The green color of the leaves of plants is extracted by rectified spirit of wine and by oils. The spirituous tinctures are generally of a fine deep green, even when the leaves themselves are dull-colored, or yellowish, or hoary. The color, however, seldom abides long even in the liquor; much less when the tinging matter is separated in a solid form, and exposed with a large surface to the air. The editor of the *Wirtemberg Pharmacopœia* observes, that the leaves of *acanthus*, or bear's breach, give a more durable green tincture to spirit than those of any other herb. Alkalis heighten the color both of the tinctures and green juices; acids weaken, destroy or change it to a brownish: lime-water improves both the color and durability: by means of lime, not elegant green lakes are procured from the leaves of *acanthus*, lilly of the valley, and several other plants. There are very few plants which com-

municate any share of their green color to water; perhaps none that give a green of any considerable deepness. The leaves of many herbs and trees give a yellow dye to wool or woollen cloth that has been previously boiled with a solution of alum and tartar. Weld, in particular, affords a fine yellow, and is commonly made use of for this purpose by the dyers, and cultivated in great quantities in some parts of England. There is no color for which we have such plenty of materials as for yellow. Mr. Hellot observes, that all leaves, barks, and roots, which on being chewed discover a slight astringency, as the leaves of the almond, peach, and pear trees, ash bark, the roots of wild patience, &c. yield durable yellows; that a large quantity of alum makes these yellows approach to the elegant yellow of weld; that if the tartar is made to prevail, it inclines them to an orange; that if the roots, barks, or leaves, be too long boiled, the yellow proves tarnished, and acquires shades of brown. See DYEING.

Indigo and weld are the most capital preparations from the leaves of plants. They are both very much used in dyeing, though the first only in painting. See INDIGO and WOAD. Both the indigo and woad plants give out their color, by proper management, to water, in form of a blue fecula or lake. Mr. Hellot supposes that a little blue fecula is procurable from many other vegetables. Dr. Lewis, however, never was able to produce the least appearance of either blue or yellow from any of the plants he tried by treating in the manner used for the preparation of indigo.

There are various mosses which, like the indigo and woad plants, promise nothing of the elegant colors that can be extracted from them by art. The most remarkable of these is ARCHIL; see that article. Linnæus suspects that there are several other more common mosses from which valuable colors might be extracted; a quantity of sea moss having rotted, in heaps, on the shore, he observed the liquor in the heaps to be as red as blood; the sea-water, the sun, and the putrefaction, having brought out the color. Mr. Kalm, in an appendix to Linnæus's paper, in 1745, mentions two sorts of mosses actually employed in Sweden for dyeing woollen red: one is the lichenoides coralliforme apicibus coccineis of Ray's synopsis; the other the lichenoides tartareum, farinaceum, scutellarum umbone fusco, of Dillenius. This last is a white substance like meal clotted together, found on the sides and tops of hills. It is shaved off from the rocks after rain, purified from the stony matters intermixed among it, by washing with water, then dried in the sun, ground in mills, and again washed and dried: it is then put into a vessel with urine, and set by for a month: a little of this tincture added to boiling water makes the dyeing color.

In the Philosophical Transactions for 1754, there is an account of another moss which, prepared with urine, gives a beautiful and durable red or violet dye to wool and silk. This is the lichen foliaceus umbilicatus subtus lacunensis, Linnæi flora Suecica. It grows upon rocks, and is readily distinguishable from others of that class by looking as if burnt or parched, consisting of leaves as thin as paper, convex all over on the

upper side, with corresponding cavities underneath, adhering firmly to the stones by a little root under the leaves, and coming asunder, when dry, as soon as touched. It is gathered after rain, as it then holds best together, and parts easiest from the stone. In France a crustaceous moss, growing upon rocks in Auvergne, is prepared with lime and urine, and employed by the dyers as a succedaneum for the Canary archil. Mr. Hellot relates that he has met with several other mosses which, on being prepared in the same manner, acquire the same color. The most expeditious way, he says, of trying whether a moss will yield an argil, or not, is to moisten a little of it with a mixture of equal parts of spirit of sal ammoniac and strong lime water, and add a small proportion of crude sal ammoniac. The glass is then to be tied over with a piece of bladder, and set by for three or four days. If the moss be of the proper kind the little liquor which runs from it, upon the inclining vessel, will appear of a deep crimson color; and, this afterwards evaporating, the plant itself acquires the same color.

Dr. Lewis informs us, that he has tried a good number of the common mosses, many both of the crustaceous and foliaceous kind, and not a few of the fungi; as also the herbs chamomile and milfoil, which yield a blue essential oil; and thyme, whose oil becomes blue by digestion with volatile spirits; but never met with any that yielded a color like archil. Most of them gave a yellow or reddish-brown tincture. A few gave a deep red color to the liquor; but, when diluted, it showed a yellowish cast, and when applied on cloth it gave only a yellowish-red. Though, in general, the blue colors of flowers are exceedingly perishable, there seem to be at least two exceptions to this rule; for the blue flowers of iris, or fleur-de-lis, and those of columbine, when treated with solution of tin, yielded a color tolerably permanent. Indeed, when experiments are made with a view to extract the color from any part of a vegetable, it should always be tried whether it can bear a mixture with this solution. If the color is not destroyed by it there is a very great probability that the solution will, by proper management, preserve and give a durability to it, which could scarcely be obtained by any other method.

There are several substances, however, used in color-making, with which solution of tin cannot bear to be mixed. These are, principally, sugar of lead and cream of tartar, as well as all the calcareous earths and alkaline salts. With alum it may be mixed very safely, and is in many cases the better for it. The roots of plants, however, seem to promise more durability of color than the upper parts. We have seen a blue color, of considerable durability and brightness, prepared from the roots of common radishes by expressing the juice, combining it with pipe-clay, and brightening it with a little alum.

In preparing liquid colors for maps, &c., there can be very little difficulty, if what is above laid down is attended to. The only color with which there can be any difficulty is blue; but the common solutions of indigo in alkalis or acids may be made to answer this purpose, though, on

account of their strongly saline qualities, they are not very proper. A method of procuring a beautiful transparent blue color is to extract the coloring matter from the Prussian blue, by caustic alkali. This laid upon paper appears of a dirty brown color; but, when washed over with a weak solution of green vitriol, is instantly changed to a most beautiful blue. This affords a method of procuring blue transparent colors of greater beauty than are usually met with. For further information, on this subject, see *PAINTING*, and *Tungri's Painters' and Varnishers' Guide*.

The following are the dye-stuffs used by the calico printers for producing fast colors. The mordants are thickened with gum, or calcined starch, and applied with the block, roller, plates, or pencil.

1. Black. The cloth is impregnated with acetate of iron (iron liquor) and dyed in a bath of madder and logwood.

2. Purple. The preceding mordant of iron, diluted: with the same dyeing bath.

3. Crimson. The mordant for purple, united with a portion of acetate of alumine, or red mordant, and the above bath.

4. Red. Acetate of alumina is the mordant, and madder is the dye-stuff.

5. Pale red, of different shades. The preceding mordant diluted with water, and a weak madder bath.

6. Brown or pompadour. A mixed mordant, containing a somewhat larger proportion of the red than of the black; and the dye of madder.

7. Orange. The red mordant; and a bath first of madder, and then of quercitron.

8. Yellow. A strong red mordant; and the quercitron bath, whose temperature should be considerably under the boiling point of water.

9. Blue. Indigo rendered soluble and greenish-yellow colored, by potash and orpiment. It recovers its blue color by exposure to air, and thereby also fixes firmly on the cloth. An indigo vat is also made, with that blue substance diffused in water with quicklime and copperas. These substances are supposed to deoxidise indigo, and at the same time to render it soluble.

10. Golden dye. The cloth is immersed alternately in a solution of copperas and lime-water. The protoxide of iron, precipitated on the fibre, soon passes, by absorption of atmospherical oxygen, into the golden-colored deutoxide.

11. Buff. The preceding substances in a more dilute state.

12. Blue vat, in which white spots are left on a blue ground of cloth, is made by applying to these points a paste composed of solution of sulphate of copper and pipe-clay; and, after they are dried, immersing it stretched on frames, for a definite number of minutes, in the yellowish-green vat of one part of indigo, two of copperas, and two of lime, with water.

13. Green. Cloth dyed blue, and well washed, is imbued with the aluminous acetate, dried, and subjected to the quercitron bath.

In the above cases the cloth, after receiving the mordant paste, is dried, and put through a mixture of cow-dung and warm water. It is then put into the dyeing vat or copper

FUGITIVE COLORS.

All the above colors are given by making decoctions of the different coloring woods; and receive the slight degree of fixity they possess, as well as great brilliancy, in consequence of their combination or admixture with the nitro-muriate of tin.

1. Red is frequently made from Brasil and Peachwood.

2. Black. A strong extract of galls, and deuto-nitrate of iron.

3. Purple. Extract of logwood, and the deuto-nitrate.

4. Yellow. Extract of quercitron bark, or French berries, and the tin solution.

5. Blue. Prussian blue and solution of tin.

Fugitive colors are thickened with gum-tragacanth, which leaves the cloth in a softer state than gum-senegal; the goods being sometimes sent to market without being washed.

For the modes of using the different articles used in dyeing, see them under their respective names in the order of the alphabet.

COLORATE, *adj.* } Lat. *coloratus*, *colo-*
COLORATION, *n. s.* } *ro*, *colorificus*. Colored,
COLORIFICK, *adj.* } marked or stained with
some color; the art or practice of coloring; the state of being colored; that which has the power of producing dyes, tints, colors, or hues.

Some bodies have a more departable nature than others, as is evident in *coloration*; for a small quantity of saffron will tinct more than a great quantity of brasil. *Bacon.*

Amongst curiosities I shall place *coloration*, though somewhat better; for beauty in flowers is their pre-eminence. *Id. Natural History.*

In this composition of white, the several rays do not suffer any change in their *colorifick* qualities by acting upon one another; but are only mixed, and by a mixture of their colours produce white.

Newton's Optics.

Had the tunicles and humours of the eye been *co-*

lorate, many rays from visible objects would have been stopt. *Ray.*

COLOSSIS, or *COLOSSE*, in ancient geography, a considerable town of Phrygia Magna, in which the Lycus falls into a gulf, and at the distance of five stadia emerges again, and runs into the Meander. Orosius says, that in Nero's time it was destroyed by an earthquake.

COLOSSUS, } Lat. *colossus*, *colossicus*.
COLOSSAL, *adj.* } A statue of enormous mag-
COLOSSSEAN. } nitude; of the form, height,
and bigness of such a statue; giantlike.

Not to mention the walls and palace of Babylon, the pyramids of Egypt, or *colosse* of Rhodes.

There huge *colossus* rose, with trophies crowned,
And runick characters were graved around. *Pope.*

These general observations may be separately applied to the amphitheatre of Titus, which has obtained

the name of the coliseum, either from its magnitude, or from Nero's *colossal* statue: an edifice, had it been left to time and nature, which might perhaps have claimed an eternal duration. *Gibbon.*

thy mind
Expanded by the genius of the spot,
Has grown *colossal*, and can only find
A fit abode wherein appear enshrined
Thy hopes of immortality.

Byron's Child of Harold.

Colossus, the name of a celebrated statue of Apollo, at Rhodes. The Rhodians having compelled Demetrius of Macedon to raise the siege of their city, were so grateful for the supposed assistance of Apollo, that they resolved to erect an enormous brasen statue in honor of that deity: and Chares, the disciple of Lysippus, was entrusted with the project. But he had scarcely half finished the work when he found that he had expended all the money that he had demanded for the whole, which overwhelmed him so completely with grief and despair, that he hanged himself. Laches, his fellow countryman, finished the work in the space of twelve years, and placed the enormous statue on its pedestal across the entrance of the harbour, its feet placed on two rocks, so that the Rhodian vessels could pass under its legs. Pliny does not mention the latter artist, but gives all the honor to Chares. Scarcely sixty years however had elapsed before this monster of art was thrown from its place by an earthquake which broke it off at the knees. It remained in this situation till the conquest of Rhodes by the Saracens in A. D. 684, when it was beaten to pieces and sold to a Jew merchant, who loaded above 900 camels with its spoils. Its height, according to Strabo, was seventy cubits (about 100 English feet); but according to other writers it amounted to eighty cubits. Pliny relates that few persons could embrace its thumb, whilst its fingers were the size of ordinary statues. There was a winding staircase to go up to the top of it; from whence one might discover Syria, and the ships that went into Egypt. Among more modern works of this nature is the enormous colossus of San Carlo Borromeo at Arona, in the Milanese territory. It is of bronze, sixty feet in height, and has a staircase into its interior for the purpose of occasional repairs and restorations.

COLOSTRUM, the first milk of any animal after bringing forth young, called bestings. This milk is generally cathartic, and purges the mæconium; thus serving both as an aliment and medicine. An emulsion, prepared with turpentine dissolved with the yolk of an egg, is sometimes called by this name.

COLSTON (Edward), an eminent philanthropist, born at Bristol in 1636. His father was engaged in the business of a Spanish merchant, to which he succeeded, and which he carried on very successfully, so that he acquired a large fortune. He disposed of the greatest part of his wealth to charitable institutions; and besides building and endowing several alms-houses and charity schools in his native city, he gave large sums during life, as well as by will at death, to hospitals and other beneficent purposes. He died in 1721, on his birth-day, and was interred

in All Saints' church, Bristol, where a sermon is yearly preached to commemorate him.

COLT, *n. s.* & *v. a.* } Signify the young o.
COLTISH, *adj.* } Any animal. It is commonly used for the male offspring of a horse, it is also applied to a rough, skittish, is foolish fellow. The verb not only signifies to play and frisk like young animals, but partakes, says Thomson, of the Goth. *gailta, kailta*; to wanton, to be lascivious. It is also used by Shakspeare, in the sense of to befool.

And she sprong as a *colt* doth in the trave;
And, with hire hed, she writhed faste away,
And say'd I wal not kisse thee by my fay.

Chaucer's Canterbury Tales.

He was all *coltish*, full of ragerie;

And ful of jergon as a flecked pie. *Id.*

What a plague mean ye, to *colt* me thus?

Shakspeare's Henry IV.

Ay, that's a *colt*, indeed; for he doth nothing but talk of his horse. *Id. Merchant of Venice.*

As soon as they were out of sight by themselves, they shook off their bridles, and began to *colt* anew more licentiously than before.

Spenser's State of Ireland.

The *colt* hath about four years of growth, and so the fawn, and so the calf. *Bacon's Natural History.*

Like *colts* or unmanaged horses, we start at dead bones and lifeless blocks. *Taylor's Holy Living.*

No sports, but what belong to war, they know;

To break the stubborn *colt*, to bend the bow.

Dryden's Æneid.

COLT, in zoology, is peculiarly used for a young male horse; the female being called a filly.

COLTS-FOOT, *n. s.* *Tussilago*; from *colt* and *foot*. It has a radiated flower, whose disk consists of many florets, but the crown composed of many half florets: the embryos are included in a multifold flower-cup, which turns to downy seeds fixed in a bed.

COLTSFOOT. See **CACALIA**

COLTS-TOOTH, *n. s.* From *colt* and *tooth*. An imperfect or superfluous tooth in young horses; a love of youthful pleasure; a disposition to the practices of youth.

Well said, lord Sands;

Your *colts-tooth* is not cast yet?

—No, my lord; nor shall not, while I have a stump.

Shakspeare.

COLTER, *n. s.* Sax. *culter*; Lat. *culter*. The sharp iron of a plough that cuts the ground perpendicularly to the share.

COLUBER, in zoology, a genus of serpents belonging to the class amphibia. The characters are these: they have a number of scuta or hard crusts on the belly; and scutellæ or scales on the tail. Linnæus enumerates ninety-seven species under this name, distinguished solely by the number of scuta and scutellæ, and Gmelin 175. The most remarkable are the following:

1. *C. æstivus*, or the green snake, is all over of a green color. It inhabits Carolina: where it lives among the branches of trees on ties and other insects. It is of a small size, and easily becomes tame and familiar.

2. *C. annulatus*, or the little brown bead snake. is always small, and is seldom found above ground, but commonly dug up, and found twisting about the roots of shrubs and plants. All

Horned Viper.

the back and other parts of the body have transverse spots of brown and white so disposed as to have some resemblance to a string of English beads; whence probably it takes its name. It is quite harmless, and is a native of Virginia and Carolina.

3. *C. aspis*, with 146 scuta and forty-six scutellæ, is a native of France. It is poisonous, and is of a reddish color, with dusky spots on the back.

4. *C. berus*, or the common British viper, is found in many countries of Europe. It abounds in the Hebrides, and in many parts of Britain; particularly in the dry, stony, and chalky counties. According to Pennant, and other naturalists, they are viviparous, but proceed from an internal egg. This viper seldom grows longer than two feet; though Pennant tells us he once saw a female, which is nearly a third larger than the male, nearly three feet long. The ground color of the male is a dirty yellow, that of the female deeper. Its back is marked the whole length with a series of rhomboidal black spots, touching each other at the points; the sides with triangular ones; the belly entirely black. It has 146 scuta and thirty-nine scutellæ. There is a variety wholly black; but the rhomboid marks are very conspicuous, even in this, being of a deeper and more glossy hue than the rest. The head of the viper is inflated, which distinguishes it from the common snake. Catesby says, 'that the difference between the vipers and snakes or other serpents is, that the former have long hollow fangs or tusks, with an opening near the point; the neck is small, the head broad, the cheeks extending wide, scales rough, the body for the most part flat and thick; they are slow of motion; swell the head and neck when irritated, and have a terrible and ugly aspect.' The tongue is forked, the teeth small; the four canine teeth are placed two on each side the upper jaw: these instruments of poison are long, crooked, and movable; capable of being raised or depressed at the pleasure of the animal, and they instil their poison in the same manner. The vipers are said not to arrive at their full growth till they are six or seven years old; but they are capable of engendering at two or three. They copulate in May, and go about three months with their young. Mr. White informs us, in his History of Selborne, that a viper, which he opened, had in it fifteen young ones of the size of earth worms, about seven inches long. They twisted and wriggled about with great alertness; and, when touched, they erected themselves, and gaped very wide, showing immediate tokens of menace and defiance, though no fangs could be perceived, even with the help of glasses: which the author remarks, as an instance among others of that wonderful instinct which impresses young animals with a notion of the situation and use of their natural weapons, even before these weapons are formed. Mr. Pennant tells us that he has been assured of a fact mentioned by Sir Thomas Brown, though denied by the viper-catchers, that the young of the viper, when terrified, will run down the throat of the parent, and seek for shelter in its belly, in the same manner as the young of the opossum retire into the ventral pouch of the old one; whence

some have imagined that the viper is so unnatural as to devour its own young: but the food of these serpents is frogs, toads, lizards, and mice. It is also said that vipers prey on young birds: but whether on such as nestle on the ground, or whether they climb up trees for them, is quite uncertain; the fact, however, is very far from being recent; as Horace mentions it, *Epid. 1.* The viper is capable of supporting very long abstinence; some having been kept in a box six months without food, and yet not abating of their vivacity. They feed only a small part of the year, but never during their confinement; for if mice, their favorite diet, should at that time be thrown into their box, though they will kill, yet they never will eat them. When at liberty, they remain torpid throughout the winter; but, when confined, have never been observed to take their annual repose. The method of catching them is by putting a cleft stick on or near their head; after which they are seized by the tail, and instantly put into a bag. The viper-catchers are very frequently bitten by them in the pursuit of their business, yet we very rarely hear of their bite being fatal. Sallad oil, applied in time, is said to be a certain remedy. The flesh of the British viper has been celebrated as a restorative, as well as that of the foreign kind.

5. *C. chersæa* is a native of Sweden, where it is called *asping*. It is a small reddish serpent, whose bite is said to be mortal.

6. *C. constrictor*, the black snake, is a native of several parts of America. They are very long, sometimes measuring six feet, and all over of a shining black. This species is not only perfectly harmless, but extremely useful in clearing the houses of rats, which it pursues with wonderful agility. In the time of copulation it is extremely bold and fierce, and will attack mankind; but its bite has no dangerous effect. It is so swift that there is no escaping its pursuit. Many ridiculous frights have happened from this innocent reptile. As every one in America is full of the dread of the rattlesnake, men are apt to fly at the sight of any of the serpent kind. This pursues, soon overtakes, and, by twisting round the legs of the fugitive, soon brings him to the ground; but he happily receives no injury.

7. *C. luridus* of Forster, called by Mr. Catesby the brown viper, is a native of Virginia and the Carolinas. It is about two feet long and large in proportion; very slow in its motion, even when threatened with danger. When attacked it defends itself with much fierceness, and its bite is as venomous as any. It preys chiefly upon lizards.

8. *C. naja*, or *cobræ* capello, with 193 scuta and sixty scutellæ, is a native of the East Indies, and is reckoned the most poisonous of all serpents. The root of the *lignum colubinum* (*ophiorrhiza*) is said to have been pointed out to the Indians as an antidote against the bite of this serpent by the *viverra ichneumon*, a creature which fights with this serpent, and cures itself, when wounded, by eating of this plant. The Indians, when bitten, instantly chew it, swallow the juice, and apply the masticated root to the puncture. It is killed by the *ichneumon*. In India it is everywhere exhibited publicly as a

show, being previously deprived of its fangs; and is of course more universally known in that country than any other of the race of reptiles. It is carried about in a covered basket, and so managed by its proprietors as to assume, when exhibited, a kind of dancing motion; raising itself up on its lower part, and alternately moving its head and body from side to side for some minutes, to the sound of some musical instrument which is played during the time.

9. *C. prester* of Linnaeus, the black viper of Catesby, is a native of Carolina and Virginia. It is short and thick, slow of motion, spreads its head surprisingly when irritated, very flat and thick, threatening with a horrid hiss. They are very poisonous; their bite being as deadly as that of the rattlesnake. They frequent the higher lands, and are of a rusty black color.

10. *C. punctatus* of Linnaeus, called by Catesby the water viper, is a native of Carolina. According to Linnaeus it is ash-colored, variegated with yellow spots. Catesby informs us that the head and back of this serpent are brown; the belly marked transversely with yellow, and also the sides of the neck. The neck is small, the head large, and the mouth armed with the destructive fangs of the viper or rattlesnake, next to which it is reckoned the largest serpent in this country. Contrary to what is observed in most other vipers, these are very nimble and active, and very dexterous in catching fish. In summer great numbers are seen lying on the branches of trees hanging over rivers; from which, on the approach of a boat, they drop into the water, and often into the boat on the men's heads. They lie in wait in this manner to surprise either birds or fish: after the latter they plunge with surprising swiftness, and catch some of a large size, which they bring ashore and swallow whole. The tail of this animal is small towards the end, and terminates in a blunt horny point about half an inch long.

11. *C. vipera*, the common viper of the shops, has 118 scuta, and only twenty-two scutellæ. The body is very short and of a pale color, with brownish spots; the head is gibbous and covered with small scales. It is a native of Egypt and other warm countries. It has always been remarkable for its poisonous nature; insomuch that vipers, when numerous, have often been thought the ministers of divine vengeance, like the plague, famine, and other national calamities. A notion also prevailed, among the ancients, that few or none of the parts of a viper were free from poison; for which reason they made no experiments or discoveries concerning the nature of these creatures. It is now, however, proved, by undoubted experiments, that the poison of vipers, as well as of all other serpents whose bite is hurtful, lies in a bag at the bottom of their great teeth or fangs. These teeth are perforated; and, when the creature bites, the compression of the bag forces out a little drop of the poison into the wound, where it produces its mischievous effects. The purpose answered by this poisonous liquor, to the creatures themselves, is probably the destruction of their prey; for, as serpents frequently feed upon animals of very considerable magnitude and strength, they would often undoubtedly make

their escape, did not the poisonous juice instilled into the wounds made by the serpent's teeth almost instantly deprive them of life, or at least of all power to struggle with their enemy. For an account of the symptoms produced by the bites of vipers, and other venomous serpents, in the human body, together with the best methods of cure, see *MEDICINE*. After the viper is deprived of those bags which contain its poison, it is entirely harmless; nay the flesh of it is highly nutritive.

COLUBRINE, *adj.* Lat. *colubrinus*. Relating to a serpent; cunning; crafty.

COLUMBA, in ornithology, the pigeon, a genus belonging to the order of passeræ. The characters of this genus are—the bill is straight, and descends towards the point; the nostrils are oblong, and half covered with a soft tumid membrane; and the tongue is not cloven. There are about eighty species, all natives of different countries. The following are the most remarkable:—

1. *C. coronata*, or great crowned pigeon, a very large species, about the size of a turkey. The bill is black, and two inches long; the irides are red; the head, neck, breast, belly, sides, thighs, and under tail coverts, cinereous blue; the head is crested; the back, rump, scapulars, and upper tail coverts, are of a deep ash-color, with a mixture of purplish chestnut on the upper part of the back and scapulars; the wing-coverts are ash colored within, and purplish chestnut on the outside and tip; quills deep blackish ash-color; tail the same, but of a light ash-color at the tip; the legs are blackish. This species inhabits the Molucca Isles and New Guinea. Its note is cooing and plaintive, like that of other pigeons, only louder in proportion. The mournful notes of these birds alarmed the crew of Bougainville much, when in the neighbourhood of them, thinking they were the cries of the human species. In France they were never observed to lay eggs, nor in Holland, though they were kept for some time; but Scopoli says, that the male approaches the female with the head bent into the breast, making a noise more like lowing than cooing; and that they not only made a nest on trees, in the menagerie where they were kept, but laid eggs. The nest was composed of hay and stalks. The female never sat, but stood upon the eggs; and he supposed it was from this cause alone, that there was no produce. They are said to be kept by some, in the East Indies, in their court-yards, as domestic poultry. The Dutch at the Moluccas call them crown-vogel, *M. Sonnerat*, as well as *Dampier*, found these in plenty at New Guinea; and it is probable that they were originally transported from that place into *fanda*, whence the Dutch chiefly now procure them.

2. *C. Malaccensis*, the Malacca pigeon described by *Sonnerat* is little bigger than the house sparrow. It is a most beautiful species, and the flesh is said to be extremely delicate. It has been transported into the Isle of France, where it has multiplied exceedingly.

3. *C. migratoria*, or pigeon of passage, is about the size of an English wood pigeon; the bill black; iris red; the head of a dusky blue; the

breast and belly of a faint red; above the shoulder of the wing there is a patch of feathers shining like gold; the wing is covered like the head, having some few spots of black (except that the larger feathers are dark brown), with some white on the exterior vanes; the tail is very long, and covered with a black feather, under which the rest are white; the legs and feet are red. They come in prodigious numbers from the north, to winter in Virginia and Carolina. In these countries they roost upon one another's backs in such quantities, that they often break down the twigs of trees which support them, and leave their dung some inches thick below the trees. In Virginia Mr. Catesby has seen them fly in such continued trains, for three days successively, that they were not lost sight of for the least interval of time, but somewhere in the air they were seen continuing their flight southward. They breed in rocks by the sides of rivers and lakes far north of St. Lawrence. They fly to the south only in hard winters, and are never known to return.

4. *C. oenas*, or the domestic pigeon, and all its beautiful varieties, derive their origin from one species, the stock dove; the English name implying its being the stock or stem from whence the other domestic birds spring. These birds, as Varro observes, take their Latin name, *columba*, from their voice of cooing. They were, and still are, to be found in most parts of our island in a state of nature; but probably the Romans first taught the Britons how to construct pigeon houses, and make birds domestic. The characters of the domestic pigeon are these:—it is of a deep bluish ash-color; the breast dashed with a fine changeable green and purple; the sides of the neck with a shining copper color; its wings marked with two black bars, one on the coverts of the wings, the other on the quill feathers; the back white, and the tail barred near the end with black. It weighs fourteen ounces. In the wild state it breeds in holes of rocks and hollows of trees; for which reason, some style it *columba cavernalis*, in opposition to the ring dove, which makes its nest on the boughs of trees. Nature always preserves some agreement in the manners, characters, and colors of birds reclaimed from the wild state. This species of pigeon soon takes to build in artificial cavities, and from the temptation of a ready provision becomes easily domesticated. Multitudes of these wild birds migrate into the south of England: and, while the beech woods were suffered to cover large tracts of ground, they used to haunt them in myriads, reaching a mile in length, as they went out in the morning to feed. They visit Britain the latest of any bird of passage, not appearing till November, and retiring in the spring. Mr. Pennant imagines, that their summer haunts are in Sweden, as Mr. Eckmark makes their retreat thence coincide with their arrival in Britain. Numbers of them, however, breed in cliffs on the coast of Wales, and of the Hebrides. The varieties produced from the domestic breed are numerous, and extremely elegant; they are distinguished by names expressive of their several properties, as tumblers, carriers, jacobines, croppers, pouters, runts, turbites, owls, nuns, &c. The

most celebrated of these is the carrier pigeon. They are gregarious, lay only two eggs, and breed many times in the year. They bill during their courtship; the male and female sit, and also feed their young, by turns: they cast provision out of their craw into the young one's mouth; they drink, not by sipping, like other birds, but by continued draughts, like quadrupeds, and they have plaintive notes.

5. *C. palumbus*, the ring dove, is a native of Europe and Asia. It is the largest pigeon we have, and might be distinguished from all others by its size alone. Its weight is about twenty ounces; its length eighteen inches, and breadth thirty. The head, back, and coverts of the wings are of a bluish ash color; the lower side of the neck and breast are of a purplish red, dashed with ash color: on the hind part of the neck is a semi-circular line of white; above and beneath that, the feathers are glossy, and of changeable colors. This species forms its nest of a few dry sticks in the boughs of trees. Attempts have been made to domesticate them by hatching their eggs under the common pigeon in dove houses; but, as soon as they could fly, they always took to their native haunts. In the beginning of winter they assemble in great flocks, and leave off cooing, which they begin in March when they pair.

6. *C. turtur*, or turtle-dove, is a native of India. The length is twelve inches and a half, its breadth twenty-one; the weight four ounces. The irides are of a fine yellow, and the eye-lids encompassed with a beautiful crimson circle. The chin and forehead are whitish; the top of the head ash-colored mixed with olive. On each side of the neck is a spot of black feathers prettily tipped with white: the back ash-colored, bordered with olive brown; the scapulars and coverts of a reddish brown spotted with black; the breast of a light purplish red, having the verge of each feather yellow: the belly white. The tail is three inches and a half long; the two middle feathers of a dusky brown; the others black, with white tips; the end and exterior side of the outermost feathers wholly white. In the breeding season these birds are found in Buckinghamshire, Gloucestershire, Shropshire, and the west of England. They are very shy and retired, breeding in thick woods, generally of oak; in autumn they migrate into other countries.

COLUMBA (St.), a celebrated saint, sometimes called the Apostle of Scotland, who flourished in the sixth century. He founded a cell of monks in Iona, and the first religious were canons regular, of whom Columba was the first abbot; and his monks, till A. D. 716, differed from those of the church of Rome, but in the observation of Easter, and in the clerical tonsure, Columba led here an exemplary life, and was highly respected for the sanctity of his manners for many years. He is the first on record who had the faculty of the second sight, for he announced the victory of Aidan over the Picts and Saxons on the very instant it happened. He had the honor of burying in his island, Conval and Kinnatell, two kings of Scotland, and of crowning a third. At length, worn out with age, he died in Iona in the arms of his disciples; was interred there, but (as the Irish pretend) in after times

translated to Down; where, according to the epitaph, his remains were deposited with those of St. Bridget and St. Patrick:—

Hi tres in Duno tumulo tumulantur in uno;
Brigida, Patricius, atque Columba pius.

COLUMBA (St.), or the CONGREGATION OF ST. COLUMBA, a society of regular canons, who formerly had ninety-eight abbeys or monasteries in the British isles.

COLUMBANUS, a saint and a poet, born in Ireland, and brought up to a religious life among the disciples of St. Columba. He made great progress in learning, and early in life composed a book of psalms, and a number of moral poems. He is said to have belonged originally to a monastery of the name of Benchor. Columbanus passed from Britain into France, A. D. 589, and founded the monastery of Luxeuille, near Besançon. He had been kindly received and patronised by king Childebert; but he was afterwards expelled France by the tyrannical queen Brunichild, on which he retired to Lombardy, and founded the monastery of Bobio. The *Regula Cœnobialis* and *Penitentialis*, which he established in that monastery, have been published in the *Codex Regularum* compiled by the learned Holstenius.

COLUMBARIA, in ancient geography, an island on the west coast of Sicily, opposite to Drepanum; said by Zonarias to have been taken from the Carthaginians by Numerius Fabius the consul; now called Columbara.

COLUMBARY, *n. s.* Lat. *columbarium*. A dovecot; a pigeon-house.

The earth of *columbaries*, or dove-houses, is much desired in the artifice of saltpetre.

Broune's Vulgar Errors.

COLUMBIA, a county of New York, bounded on the north by Rensselaer, south by Dutchess, east by the state of Massachusetts, and west by Hudson River, which divides it from Albany county. It is thirty-two miles in length, and twenty-two in breadth, and is divided into eight towns, of which Hudson, Claverack, and Kinderhook are the chief. It is said to contain an area of 504 square miles, or 380,160 acres, which gives about fifty-four persons to a square mile, and is one of the most flourishing portions of the United States. Although no part can be called mountainous, the surface is considerably diversified. On the eastern border is a hilly track, and the intermediate country to the Hudson is gently undulated, ranges of small hillocks being interspersed with extensive plains and valleys, and with many tracts of rich alluvial soil. In the southward the soil is a deep warm gravel, diversified with hill and dale, and adapted either for grain or pasture. It contains 3742 senatorial electors.

COLUMBIA RIVER, a river of North America, which, according to Mackenzie, rises in the Rocky Mountains, in about 54° 23' N. lat., and 121° W. long., and falls into the Pacific Ocean in 46° 10' N. lat., and 122° 45' W. long. Its source is not more than a few miles from that of the Unijah or Peace River, whose waters communicate with that great line of rivers and lakes which stretch across this part of the American

continent, and terminate in the St. Lawrence. Although the discovery of this river is claimed by the Spaniards, who call it *Entrada de Ceta*, it was first entered in modern times in 1791, by Mr. Gray, in the *Columbia*, and by this name it has since been called. Lieutenant Broughton, under the orders of Captain Vancouver, afterwards explored it for about 100 miles; and on the land side it was navigated a considerable way from its source by Mackenzie, in his journey across the continent. He found numerous rapids and falls; but as the stream enlarged the navigation was less impeded. Messrs. Lewis and Clarke entered this river at the point where it is joined by Lewis's River, in lat 46° 15' 13" N. and descended the stream to the ocean.

COLUMBIA, a county of Georgia, bounded on the north and east by the savannah, which separates it from the state of South Carolina, north-west of Richmond county. Its shape is very irregular.

COLUMBIA, an extensive territory, in the most central part of the United States, where the new city of Washington, the permanent seat of the general government, since 1800, is now building, in a situation equi-distant from the north and south extremities of the Federal Union, and nearly so from Pittsburgh and the Atlantic Ocean. Mr. Morse styles it 'a commercial territory, probably the richest, and commanding the most extensive internal resources of any in America.'

COLUMBIA, a post town of Virginia, in Goochland county, on the North side of James River, at the mouth of the Rivanni. It lies forty-five miles above Richmond, thirty-five from Charlottesville, and 328 south-west of Philadelphia.

COLUMBIA, a post town of South Carolina, the capital of Kershaw county, and the seat of government in that state. It is situated in Camden district, on the east side of the Congaree, just below the confluence of Saluda and Broad Rivers. The streets are regular, and the town has doubled its population very rapidly. It lies 115 miles N. N. W. of Charleston, thirty-five south-west of Camden, eighty-five from Augusta, in Georgia, and 678 south-west of Philadelphia.

COLUMBIA, a town of Pennsylvania, in Lancaster county, on the north-east bank of the Susquehanna, at Wright's Ferry, ten miles west of Lancaster, and seventy-six west by north of Philadelphia. It was laid out in 1797.

COLUMBIA, a town in the north-western territory, on the north bank of the Ohio, and on the west side of the mouth of Little Miami River, about six miles south-east by east of Fort Washington, eight east by south of Cincinnati, and eighty-seven north by west of Lexington, in Kentucky. Long. 83° 34' W., lat. 49° 20' N.

COLUMBIA, a township in Washington county, and district of Maine, on Pleasant River, adjoining Machias on the north-east. It was incorporated in 1796. It is nine miles from Steuben.

COLUMBIC ACID, in chemistry, a white colored substance, procured from columbium, a peculiar ore, deposited in the British Museum;

and the same with the tantalite of Ekeburgh, discovered by him in the ylbrotantalite of Sweden. Dr. Wollaston's method of separating the acid from the mineral is peculiarly elegant. One part of tantalite, five parts of carbonate of potash, and two parts of borax, are fused together in a platina crucible. The mass, after being softened in water, is acted on by muriatic acid. The iron and manganese dissolve, while the columbic acid remains at the bottom. It is in the form of a white powder, which is insoluble in nitric and sulphuric acids, but partially in muriatic. It forms with barytes an insoluble salt, of which the proportions, according to Berzelius, are 24.4 acid, and 9.75 barytes. By oxidising a portion of the revived tantalum or columbium, Berzelius concludes the composition of the acid to be 100 metal and 5.485 oxygen.

COLUMBIERS, a town of France, in the department of Aveiron, and ci-devant province of Rouergue, in the district of Sauveterre, ten miles west of Rhodéz.

COLUMBINE, *n. s.* Lat. *columbina*. A plant with leaves like the meadow rue.

Columbines are of several sorts and colours. They flower in the end of May, when few other flowers shew. *Mortimer.*

Co'LUMBINE, *n. s.* Lat. *columbinus*. A kind of violet color, or changeable dove color.

COLUMBIUM, the metallic basis of the Columbic acid: the ore first discovered was from Massachusetts. It was of a dark brownish-gray externally, and more inclining to an iron-gray internally; the longitudinal fracture he found lamellated, and the cross fracture had a fine grain. Its lustre was vitreous, slightly inclining, in some parts, to metallic; moderately hard, and very brittle. The color of the streak, or powder, was dark chocolate brown. 'If the oxide of columbium, described under **COLUMBIC ACID**, be mixed with charcoal and exposed to a violent heat in a charcoal crucible, the metal columbium will be obtained. It has a dark gray color, and when newly abraded, the lustre nearly of iron. Its specific gravity, when in agglutinated particles, was found by Dr. Wollaston to be 5.61. These metallic grains scratch glass, and are easily pulverised. Neither nitric, muriatic, nor nitro-muriatic acid, produces any change in this metal, though digested on it for several days. It has been alloyed with iron and tungsten.'

COLUMBO, a town on the western coast of the island of Ceylon, where the Portuguese had a settlement; but which, after a bloody struggle, surrendered to the Dutch in 1656, from whom it was taken by the British in 1796. Columbo is the capital of the island, and the seat of government, although Trincomalee occupies more ground, and, on account of its situation and harbour, is considered of more consequence to this nation. In every other respect Columbo has by far the superiority. The country round Trincomalee is mountainous, wild, and barren; but Columbo is situated in a fertile country, and the rich district depending upon it is much wider, being nearly twenty leagues in length, and ten in breadth. Though the principal har-

bours in the island be at Trincomalee and Point de Galle, at certain seasons of the year they moor securely in the roads of Columbo. The town is built on a regular plan, being nearly divided into four equal quarters by two principal streets, which cross each other, and extend from side to side, with smaller ones running parallel, and connected by lanes between them. The natives live in the old town, without the walls of the new. The fort is much larger than that of Trincomalee; at the foot of the ramparts, on the inside, is a broad street or way, which goes round the whole fort, and communicates with the bastions and soldiers' barracks; and also affords, at the different angles, open spaces for their private parading. The governor's house is a handsome structure. There is here a fine botanical garden, and a school for the propagation of the Christian religion.

Columbo was the first European settlement on the island of Ceylon. The Portuguese arrived here in the year 1505, in the reign of Dermaprakrama-bahoo, king of Candy. The natives, who first saw the strangers, informed the king 'that a new people was arrived, white and beautifully made, who wore iron coats and iron caps, and drank blood and ate stones; who gave a gold coin for a fish, or even a lime; and who had a kind of instrument that could produce thunder and lightning, and balls which, put into these instruments, would fly many miles, and break ramparts, and destroy forts.' The king's brother examined them in disguise, and by his advice the Portuguese were well received, and permitted to trade and establish a settlement here.

'During the remainder of this reign, and the whole of the next, which was a short one,' says Dr. Davy, in his Sketch of the History of Ceylon, 'the Portuguese had very little influence in the country, and they remained in their original capacity of traders. In the next reign, that of Boowanyka-bahoo, in consequence of dissensions in the royal family, they began to gain ground and acquire political power. Engaged in a war with his brother Mitidoony, who refused to acknowledge the king's grandson as his successor, he sent an embassy to Portugal, with a figure of the infant prince in wax, begged protection for the child and his kingdom, and requested aid, which was most readily granted. The young prince was christened Don Juan Derma-pali. Troops were sent to Ceylon, with abundance of ammunition, to make good the promise that had been given. For some time, wherever the Portuguese appeared they were victorious. The king himself was almost one of the first to fall, by the new engines of war introduced; he was shot through the head when going to oppose his brother. He is said, by the native historians, to have ruined his country and religion, by his unnatural policy of having recourse to the Portuguese.

'During the life of his successor the island was in the most disturbed state; but Rajah Singha, of Sittawakka, succeeding, carried on the war with great vigor: he overcame all the native princes who opposed him; took Cotta, and destroyed it; besieged Columbo, and reduced the Portuguese to great straits. After his death the

Portuguese were again successful; they took Avisahavellé, possessed themselves of the whole of the maritime provinces, and of a great part of the Seven Korles, and seemed to have a fair prospect of becoming masters of the whole island. The only obstacle in the way of their ambition, was Maha-Wimmala-derma, a native prince of spirit and abilities, who, in the civil wars of the interior, when very young, had taken refuge at Colombo, from whence he was sent to Goa, and from thence, when the Portuguese were in danger of being driven out of the country by Rajah Singha of Sittawakka, he was sent back to Ceylon, to make a diversion in the high country in favor of his friends. He accomplished this, and more than was desired; he established himself at Singada-galla or Kandy, as an independent monarch, and governed the greater part of the country now included in the Kandyan provinces.

He was succeeded by his brother Sennerat. At this time the greater part of the island had submitted to the Portuguese. But this prince made successful incursions upon the borders, and with the other native princes recovered the whole except Colombo, Galle, Jaffna, and Trincomalee.

To expel the European intruders entirely, the princes, in the middle of the seventeenth century, formed an alliance with the Dutch. Galle surrendered to the Dutch fleet; and, in about sixteen years after (1658), the Portuguese power in Ceylon was annihilated. We have sketched the rest of the history of its European connexion in the article CEYLON, which see.

This place lost its first three British governors within the space of one year. Colonel Petrie and general Doyle died, and colonel Bonnevaux of the Company's service was killed by the upsetting of his carriage. 'The Pettah, or black town of Colombo,' says Mr. Hamilton, 'deserves particular notice on account of its extent and structure. In the street next to the sea is an excellent fish-market, well supplied from the sea, lakes, and rivers in the neighbourhood; fish being a considerable part of the food of the inhabitants. On the rivers in the vicinity of Colombo there are nearly 300 flat-bottomed boats moored, with entire families on board, who reside permanently in them, having no other dwellings. Colombo, for its size, is one of the most populous places in India, being estimated to contain above 50,000 inhabitants, who are a great mixture of almost every race of Asiatics. The language most universally spoken both by Europeans and Asiatics, who resort to Colombo, is the Portuguese of India, a base corrupt dialect, differing much from that spoken in Portugal.'

In the neighbourhood is made a considerable quantity of arrack; and cinnamon and pepper, the staple spices of the island, are largely exported hence to Europe. The imports are grain, cotton, and calico, coarse cloths, stockings, handkerchiefs, China-ware, tin, copper, and toys. About February in every year arrives a ship from Macao with hams, sugar, sweetmeats, teas, silks, velvets, nankeens, earthenware, &c. Accounts are kept in six dollars, a nominal coin, valued at a certain quantity of copper money, equal to about two shillings sterling. At this period cash is plentiful, and the whole town exhibits much of the bustle

of commerce. Beef, fish, pigs, and ducks, are generally both cheap and plentiful at Colombo. Mutton is dear, as no sheep can be reared in the vicinity; of which the abundance of cinnamon trees constitutes a great ornament.

COLUMBO ROOT, in medicine. This root comes to us in circular pieces, from half an inch or an inch to three inches in diameter, and divided into frusta, which measure from two inches to one quarter of an inch. The sides are covered with a thick corrugated bark, of a dark brown hue on its external surface, but internally of a light yellow color. All the thicker pieces have small holes drilled through them, for the convenience of drying. Colombo root has an aromatic smell; but is disagreeably bitter, and slightly pungent to the taste, somewhat resembling mustard seed, when it has lost, by long keeping, part of its essential oil. It appears to be corroborant, antiseptic, and powerfully anti-emetic. In the cholera morbus it alleviates the violent tormino, checks the purging and vomiting, corrects the putrid tendency of the bile, quiets the inordinate motions of the bowels, and recruits the exhausted strength of the patient. Its efficacy has also been observed in the vomitings which attend the bilious cholice; and in such cases, where an emetic is thought necessary, after administering a small dose of ipecacuanha, the stomach may be washed with an infusion of Colombo root.

COLUMBUS (Christopher), the celebrated navigator, and first discoverer of the islands of America, was a native of the republic of Genoa. Neither the time nor place of his birth, however, are known with certainty; except that he was descended of an honorable family, who, by various misfortunes, had been reduced to indigence. His parents were sea-faring people; and Columbus having discovered, in his early youth, an inclination for that mode of life, was encouraged by them to follow the same profession. He went to sea at the age of fourteen: his first voyages being to those ports in the Mediterranean frequented by the Genoese: after which he took a voyage to Iceland; and, proceeding still further north, advanced several degrees within the polar circle. After this Columbus entered into the service of a famous sea captain of his own name and family. This man commanded a small squadron, fitted out at his own expense; and by cruising, sometimes against the Mahomedans and sometimes against the Venetians, the rivals in this country in trade, had acquired both wealth and reputation. With him Columbus continued for several years, no less distinguished for his courage than experience as a sailor. At length, in an obstinate engagement off the coast of Portugal, with some Venetian caravans returning richly laden from the Low Countries, the vessel on board which he served took fire, together with one of the enemies' ships to which it was fast grappled. Columbus threw himself into the sea; laid hold of a floating oar; and by the support of it, and his dexterity in swimming, reached the shore, though about two leagues distant. After this disaster, Columbus repaired to Lisbon, where he married a daughter of Bartholomeu Peres-

trelo, one of the captains employed by prince Henry in his early navigations, and who had discovered and planted the islands of Porto Santo and Madeira. Having obtained possession of the journals and charts of that experienced navigator, Columbus was seized with an irresistible desire to visit unknown countries. He first made a voyage to Madeira, and continued for several years to trade with that island, the Canaries, Azores, the settlements in Guinea, and all the other places which the Portuguese had discovered on the continent of Africa. By the experience acquired in such a number of voyages, Columbus now became one of the most skilful navigators in Europe. At this time, the great object of discovery was a passage by sea to the East Indies. This was attempted, and at last accomplished by the Portuguese, by doubling the Cape of Good Hope. The danger and tediousness of the passage, however, supposing it to be really accomplished, which as yet it was not, set Columbus on considering whether a shorter and more direct passage to these regions might not be found out; and, after long consideration, he became thoroughly convinced, that, by sailing across the Atlantic Ocean, directly towards the west, new countries, which probably formed a part of the vast continent of India, must infallibly be discovered. His conjectures were confirmed by the observations of modern navigators. A Portuguese pilot having stretched farther to the west than usual, took up a piece of timber, artificially carved, floating upon the sea; and as it was driven towards him by a westerly wind, he concluded that it came from some unknown land situated in that quarter. Perestrello had found to the west of the Madeira isles a piece of timber fashioned in the same manner, and brought by the same wind; and had seen also canes of an enormous size floating upon the waves, which resembled those described by Ptolemy, as productions peculiar to the East Indies. After a course of westerly winds, trees torn up by the roots were often driven upon the coast of the Azores; and at one time the dead bodies of two men with singular features, which resembled neither the inhabitants of Europe nor Africa, were cast ashore there. Even the mistakes of ancient geographers, as to the immense extent of India, as well as various other reasons, contributed to persuade Columbus, that the shortest and most direct course to the remote regions of the east, was to be found by sailing due west. Having already given a particular account of this great man's fruitless applications to the senate of Genoa, and the courts of Portugal and Spain, &c. as well as of his ultimate success with the latter, under the article AMERICA, it is only necessary here to mention the chief articles of his treaty with Ferdinand and Isabella; which was signed on the 17th of April, 1492. These were, that Columbus should be constituted high admiral in the seas, islands, and continent he should discover, with the same powers and prerogatives that belonged to the high admiral of Castile within the limits of his jurisdiction. He was also appointed viceroy in all those countries to be discovered; and a tenth of the products accruing from their productions

and commerce was granted to him for ever. All controversies or law-suits with respect to mercantile transactions were to be determined by the sole authority of Columbus, or of judges to be appointed by him. He was also permitted to advance one-eighth part of the expense of the expedition, and of carrying on commerce with the new countries; and was entitled, in return, to an eighth of the profit. But, though the name of Ferdinand was joined with Isabella in this transaction, his distrust of Columbus was still so violent, that he refused to take any part in the enterprise as king of Arragon; and, as the whole expense of the expedition was to be defrayed by the crown of Castile, Isabella reserved for her subjects of that kingdom an exclusive right to all the benefits which might accrue from its success. Not to repeat the account of his long and perilous voyage, already fully narrated under AMERICA, it is sufficient to mention here, that, after obtaining his grand object, the discovery of the New World, he returned to Spain and arrived at the port of Palos, on the 15th of March, 1493. As soon as the ship was discovered approaching, all the inhabitants of Palos, ran eagerly to the shore, where they received the admiral, with royal honors. The court was then at Barcelona, and Columbus immediately acquainted the king and queen of his arrival. They were no less delighted than astonished with the unexpected event. They gave orders for conducting him into the city with all imaginable pomp. They received him clad in their royal robes, and seated on a throne under a magnificent canopy. When he approached, they stood up; and raising him as he knelt to kiss their hands, commanded him to take his seat upon a chair prepared for him, and to give a circumstantial account of his voyage. When he had finished his oration, which he delivered with much modesty and simplicity, the king and queen, kneeling down, offered up solemn thanks to God for the discovery. Every possible mark of honor that could be suggested by gratitude or admiration was conferred on Columbus; the former arrangement was confirmed, his family was ennobled, and a fleet ordered to be equipped, to enable him to go in quest of those more opulent countries which he still confidently expected to find. Notwithstanding all this respect, however, Columbus was no longer regarded than he was successful. The colonists he carried over were to the last degree unreasonable and unmanageable; so that he was obliged to use some severities towards them; and malicious complaints were made to the court of Spain against him for cruelty. On this, Francis de Bovadilla, a knight of Calatrava, was appointed to enquire into the conduct of Columbus; with orders, in case he found the charge of maladministration proved, to supersede him, and assume the office of governor of Hispaniola. The consequence of this was, Columbus was sent to Spain in chains, which he indignantly wore in the royal presence, and ordered that they should be buried with him. Notwithstanding his great services, and the solemnity of the agreement between him and Ferdinand, Columbus never could obtain the fulfilment of any

part of that treaty; so that disgusted with the ingratitude of a monarch, whom he had served with so much fidelity and success, and exhausted with fatigue, he ended his active and useful life at Valladolid, on the 20th of May, 1506, in the fifty-ninth year of his age. He was grave, though courteous in his deportment, circumspect in his words and actions, irreprouchable in his morals, and exemplary in his religious duties. The following anecdote, which is related of him, will give some idea of his sagacity. While his vessels lay off Hispaniola, the Indians neglected to bring the provisions he had agreed for; on which he sent for the chiefs, and informed them that the God of the Christians was angry at their breach of faith, and as a proof of it, the following night the moon would rise with a threatening and bloody aspect. He knew that there would be an eclipse that night; but the Indians made light of the prediction till they saw it verified; on which, in great terror, they supplicated his forgiveness, and ever after brought the stipulated supplies regularly. Ferdinand, notwithstanding his ingratitude during his life, buried him magnificently in the Cathedral of Seville, and erected a tomb over him with this inscription, 'A Castilia y a Leon Nuevo Mundo dio Colon;' Columbus has given a New World to Castile and Leon.

COLUMBUS (Bartholemew), brother to Christopher, famous for his marine charts and spheres, which he presented to Henry VII. of England. See AMERICA. He died in 1514.

COLUMBUS (Don Ferdinand), the son of Christopher, and writer of his life. He entered into orders; and founded a library which he bequeathed to the church of Seville, to this day called the Columbine library. He died in 1560.

COLUMELLA (Lucius Junius Moderatus), a Roman philosopher, was a native of Cadiz, and lived under the emperor Claudius about A.D. 42. He wrote a book on agriculture, entitled *De Re Rustica*, and another *De Arboribus*.

COLUMELLA, in botany, a genus of plants of the order polygamia superflua, class syngenesia. Receptaculum, naked and cellular: CAL. cylindrical and imbricated; florets undivided: SEED crowned with a toothed margin. Species one only; a native of the Cape, having fine yellow flowers.

COLUMN, *n. s.* Lat. *columna*. A round pillar.

Some of the old Greek *columns* and altars, were brought from the ruins of Apollo's temple, at Delos.

Peacham.

Round broken *columns* clasping ivy twined. *Pope.*

Where famed St. Giles's ancient limits spread,
An irrailed *column* rears its lofty head,
An here to seven streets seven dials count the day,
And from each other catch the circling ray. *Gay.*

Of many a statue the place was marked by an empty pedestal; of many a *column*, the size was determined by a broken capital. *Gibbon.*

Tully was not so eloquent as thou,
Thou nameless *column* with the buried base.

Byron's Childe Harold.

Any body of certain dimensions pressing vertically upon its base.

The whole weight of any *column* of the atmosphere, and likewise the specific gravity of its basis, are certainly known by many experiments. *Bentley.*

In the military art. The long file or row of troops, or of baggage, of an army in its march; an army marches in one, two, three, or more columns, according as the ground will allow.

With printers, a column is half a page, when divided into two equal parts by a line passing through the middle, from the top to the bottom; and, by several parallel lines, pages are often divided into three or more columns.

COLUMN. See ARCHITECTURE.

COLUMN, ASTRONOMICAL, a kind of observatory, in form of a very high tower built hollow, and with a spiral ascent to an armillary sphere placed a-top for observing the motions of the heavenly bodies. Such is that of the Doric order erected at the Hotel de Soissons at Paris by Catherine de Medicis, for the observations of Orontius Fineus a celebrated astronomer of that time.

COLUMN, CHRONOLOGICAL, that which bears some historical inscription digested according to the order of time; as by lustris, olympiads, fasti, epochas, annals, &c. At Athens there were columns of this kind, whereon were inscribed the whole history of Greece digested into olympiads.

COLUMN, FUNERAL, that which bears an urn, wherein are supposed to be enclosed the ashes of some deceased hero; and whose shaft is sometimes overspread with tears and flames, which are symbols of grief and of immortality.

COLUMN, GNOMONIC, a cylinder whereon the hour of the day is represented by the shadow of a stile. See DIAL.

COLUMN, HISTORICAL, is that whose shaft is adorned with a basso-relievo, running in a spiral line its whole length, and containing the history of some great personage: such are the Trajan and Antonine columns at Rome.

COLUMN, HOLLOW, that which has a spiral staircase withinside, for the convenience of ascending to the top; as the Trajan column, the staircase whereof consists of 185 steps, and is illuminated by forty-three little windows, each of which is divided by tambours of white marble. The monument, or fire-column, at London, has also a stair-case, but it does not reach to the top. These kinds of columns are also called *columnæ coelidæ*, or *cochlidæ*.

COLUMN, INDICATIVE, that which serves to show the tides, &c. along the sea-coasts. Of this kind there is one at Grand Cairo of marble, whereon the overflowings of the Nile are expressed; by this they form a judgment of the succeeding season; when the water, for instance, ascends to twenty-three feet, it is a sign of great fertility in Egypt. See NILOMETER.

COLUMN, INSTRUCTIVE, that raised, according to Josephus, lib. i. cap. 3, by the sons of Adam, whereon were engraven the principles of arts and sciences. Baudelot tells us, that the son of Pisistratus raised another of this kind, of stone, containing the rules and precepts of agriculture.

COLUMN, JUBILEARY, a column with several

faces, placed in the cross ways in large roads; serving to show the different routes by inscriptions thereon.

COLUMN, LACTARY, at Rome, according to Festus, was a column erected in the herb-market, now the place Montanara, which had a cavity in its pedestal, wherein young children abandoned by their parents, out of poverty or inhumanity, were exposed, to be brought up at the public expense.

COLUMN, LEGAL. Among the Lacedemonians there were columns raised in public places, whereon were engraven the fundamental laws of the state.

COLUMN, LIMITROPHOUS, or BOUNDARY, that which shows the limits of a kingdom or country conquered. Such was that which Pliny says Alexander the Great erected at the extremity of the Indies.

COLUMN, MANUBIARY, from *manubia*, Latin, spoils of the enemy; a column adorned with trophies built in imitation of trees, whereon the spoils of enemies were anciently hung. See **TROPHY**.

COLUMN, MEMORIAL, one raised on occasion of any remarkable event; as the monument of London, built to perpetuate the memory of the burning of the city in 1666. It is of the Doric order, fluted, hollow, with a winding staircase; and terminated at top with waving flames. There is also another of this kind, in form of an obelisk, on the banks of the Rhine, in the Palatinate, in memory of the famous passage of that river by the great Gustavus Adolphus and his army.

COLUMN, MENIAN, any column which supports a meniana or balcony. The origin of this kind of column, Suetonius and Ascanius refer to one Menias; who, having sold his house to Cato and Flaccus, consuls, to be converted into a public edifice, reserved to himself the right of raising a column without-side, to bear a balcony, whence he might see the shows.

COLUMN, MILITARY, among the Romans, a column whereon was engraven a list of the forces in the Roman army, ranged by legions, in their order; to preserve the memory of the number of soldiers, and of the order observed in any military expedition. They had another kind of military column, which they called *columna bellica*, standing before the temple of Janus; at the foot of which the consul declared war, by throwing a javelin towards the enemy's country.

COLUMN, MILITARY, was a column of marble, raised by order of Augustus, in the middle of the Roman forum; from whence, as a centre, the distances of the several cities, &c. of the empire were reckoned, by other military columns disposed at equal distances on all the grand roads. It was of white marble, the same with that which is now seen on the balustrade of the perron of the capitol at Rome. Its proportion is massive, being in a short cylinder, the symbol of the globe of the earth. It was called *militarium aureum*, as having been gilt, at least the bail, by order of Augustus. It was restored by the emperors Vespasian and Adrian, as appears by the inscriptions.

COLUMN, SEPULCHRAL, anciently was a co-

lumn erected on a tomb or sepulchre, with an inscription on its base. Those over the tombs of persons of distinction were very large; those for the common people small: these last are called *stelæ* and *cippi*.

COLUMN, STATUARY, that which supports a statue. Such was that erected by pope Paul V., on a pedestal before the church of St. Maria, at Rome, to support a statue of the virgin, which is of gilt brass. This column was dug up in the temple of Peace; its shaft is a single block of white marble, forty-nine feet and a-half high, and five feet eight inches diameter, of the Corinthian order. The term may also be applied to Caryatides, Persians, termini, and other human figures, which do the office of columns, and which Vitruvius call *telamones* and *atlantes*. See **ARCHITECTURE, Index**.

COLUMN, TRIUMPHAL, a column erected among the ancients in honor of a hero; the joints of the stones, or courses of which were covered with as many crowns as he had made different military expeditions. Each crown had its particular name, as *vallis*, which was beset with pikes in memory of having forced a pallisade; *muralis*, adorned with little turrets or battlements, for having mounted an assault; *navalis*, of prows and beaks of vessels, for having overcome at sea; *obsidionalis*, or *graminalis*, of grass, for having raised a siege; *ovans*, of myrtle, which expressed an ovation, or little triumph; and *triumphalis*, of laurel, for a grand triumph. See **CROWN**.

COLUMNA, a town of Russia, in the government of Moscow, with an archbishop's see fifty miles south-east of Moscow.

COLUMNAR, adj. From column. Form-
COLUMNARIAN, adj. Used in columns.

White *columnar* spar, out of a stone-pit. *Woodward*.

COLUMNARIUM, in Roman antiquity, a heavy tribute, demanded for every pillar of a house. It was first laid on by Julius Cæsar, to put a stop to the extravagant expenses laid out on sumptuous buildings.

COLUMNIA, in botany, a genus of the class didynamia, order angiosperma: *cal.* quinque-partitè: *cor.* upper lip arched, and entire gibbous, antheræ convex: *caps.* bilocular. Species four, natives of the West Indies.

COLORS, n. s. Lat. *colori*; *κόλορες*.

Two great circles supposed to pass through the poles of the world: one through the equinoctial points, Aries and Libra; the other through the solstitial points, Cancer and Capricorn. They are called the equinoctial and solstitial *colors*, and divide the ecliptick into four equal parts. The points where they intersect the ecliptick are called the cardinal points. *Harrie*.

Thrice the equinoctial line

He circled; four times crossed the ear of night

From pole to pole, traversing each *color*. *Milton*.

COLURI, or COLOURI, a small island in the gulph of Engia, in the Archipelago, formerly Salamis.

COLURI, the capital of the above island, seated on the south side, at the bottom of the harbour, which is one of the finest in the world. The famous Grecian hero Ajax, was king of this island, and it is famous in ancient history for the defeat

of the fleet of Xerxes, by that of the Greeks, under Themistocles, in the strait. It is now, however, but a small place; its commodities consist of wheat, barley, tar, rosin, pit-coal, sponges, and pot-ashes, which they carry to Athens. It is seven miles south from Athens, and is separated from the continent by a strait about a mile over.

COLUTEA, bladder senna, in botany; a genus of the decandria order, and diadelphia class of plants; natural order thirty-second, papilionaceæ; CAL. quinquefid; legumes inflated, opening at the upper part of the base. There are thirteen species, all deciduous flowering shrubs, adorned with many lobed leaves, and butterfly-shaped flowers, of a deep yellow or red color. They are propagated both by seeds and layers, and are hardy plants, though they sometimes require a little shelter when the weather is very cold.

COLYBA, or **COLYBES**, in the Greek liturgy, an offering of corn and boiled pulse, made in honor of the saints and for the dead. The Greeks boil a quantity of wheat, and lay it in little heaps on a plate, separated from each other by leaves of parsley, adding beaten peas, nuts cut small, and grape stones. A little heap of wheat, thus seasoned, they call *κολυβα*. They have a particular formula for the benediction of the *colybae*. Balsamon refers the institution of this superstition to St. Athanasius; but the Greek Synaxary to the time of Julian the Apostate.

COLYMBUS, in ornithology, a genus belonging to the order of anseres. The bill has no teeth, subulated, straight, and sharp-pointed; the teeth are in the throat; the nostrils are linear, and at the base of the bill; and the legs are unfit for walking. This genus includes the divers, guillemots, and grebes, of which the following are the most remarkable species:—

1. *C. arcticus*, or the black-throated diver, weighs about three pounds, and measures more than two feet to the end of the tail, and about three feet and a-half in breadth. The bill and the front are black; the hind part of the head and neck cinereous; the sides of the neck marked with black and white lines pointing downwards; the fore part of a glossy variable black, purple, and green. The back, scapulars, and coverts of the wings are black, marked, the two first with square, the last with round spots of white; the quill-feathers dusky; the breast and belly white; the tail short and black, legs partly dusky and partly reddish. This species is found in England, but is not common. It abounds in the northern parts of Europe, Norway, Sweden, and Denmark; in the inland lakes of Siberia; in Iceland, Greenland, the Ferroe Isles; and at Hudson's Bay. The Swedes dress their skins, which, like those of all this genus, are exceedingly tough, and use them for gun-cases and facings for winter caps.

2. *C. auritus*, the eared grebe, or dib-chick, is in length one foot to the rump; the extent is twenty-two inches; the bill black, slender, and slightly recurved; the irides crimson; the head and neck are black; the throat spotted with white; the whole upper side a blackish-brown, except the ridge of the wing about the first joint, and the secondary feathers, which are white; the

breast, belly, and inner coverts of the wings are white; the sub-axillary feathers, and some on the side of the rump, ferruginous. Behind the eyes, on each side, is a tuft of long, loose, rust-colored feathers hanging backwards; the legs are of a dusky-green. They inhabit the fens near Spalding, where they breed. No external difference is to be observed between the male and the female of this species.

3. *C. cornutus*, the horned grebe, is about the size of a teal; weight, one pound; length, one foot; breadth, sixteen inches. Bill, one inch, dusky; head very full of feathers, and of a glossy deep green, nearly black; through each eye is a streak of yellow feathers, elongated into a tuft as it passes to the hind head: the upper part of the neck and back is dusky-brown: the fore part of the neck and breast dark orange-red; the lesser wing-coverts, cinereous; the greater wing and quills, black; middle ones, white; belly, glossy-white; legs, cinereous blue before, pale behind. It inhabits Hudson's Bay; and first appears in May, about the fresh waters. It lays from two to four white eggs in June, among the aquatic plants; and is said to cover them when abroad. It retires south in autumn; appears then at New York, staying till spring, when it returns to the north. For its vast quickness in diving, it is called the water-witch. At Hudson's Bay it is known by the name of seekoop.

4. *C. cristatus*, the crested diver, or cargoose, weighs two pounds and a half. Its length is twenty-one inches, the breadth thirty; the bill is two inches and a quarter long, red at the base and black at the point; between the bill and the eye is a stripe of black naked skin; the irides are a fine pale red; the tongue is a third part shorter than the bill, slender, hard at the end, and a little divided; on the head is a large dusky crest, separated in the middle. The cheeks and throat are surrounded with a long pendent ruff, of a bright tawny color, edged with black; the chin is white; from the bill to the eye is a black line, above that a white one; the hind part of the neck and back are of a sooty hue; the rump, for it wants its tail, is covered with a long soft down. The covert feathers on the second and third joints of the wing, and the under coverts are white; all the other wing feathers, except the secondaries, are dusky, those being white: the breast and belly are of a most beautiful silvery white, glossy as satin: the outside of the legs and the bottom of the feet are dusky; the inside of the legs and the toes a pale green. These birds frequent the meres of Shropshire and Cheshire, where they breed; and the great fen of Lincolnshire, where they are called gaunts. Their skins are made into tippets, and sold at as high a price as those which come from Geneva. This species lay four eggs of a white color, and the same size with those of a pigeon. The nest is formed of the roots of bugbane, stalks of water lily, pond weed, and water violet, floating among the reeds and flags; the water penetrates it, and the bird sits and hatches the eggs in that wet condition; the nest is sometimes blown from among the flags into the middle of the water. It is a careful nurse of its young, and feeds them most assiduously.

duously, commonly with small eels. When the infant brood are tired, the parent will carry them either on its back or under its wings. It preys on fish, and is almost perpetually diving; it does not show much more than the head above water; and is very difficult to be shot, as it darts down on the least appearance of danger. It is never seen on land; and though disturbed ever so often, will not fly farther than the end of the lake. Its skin is out of season about February, losing then its bright color; and in the breeding time its breast is almost dark. The flesh is excessively rank.

5. *C. glacialis*, or northern diver, is three feet five inches in length; the breadth four feet eight inches; the bill to the corner of the mouth four inches long, black and strongly made. The head and neck are of a deep black; the hind part of the latter is marked with a large semilunar white band; immediately under the throat is another; both marked with oblong strokes pointing down; the lower part of the neck is a deep black, glossed with a rich purple; the whole under side of the body is white; the sides of the breast marked with black lines; the back, coverts of the wings, and scapulars, are black marked with white spots; those on the scapulars are very large, and square shaped; two at the end of each feather. The tail is very short, and almost concealed by the coverts, which are dusky, spotted with white; the legs are black. This species inhabits several parts of the north of Europe, but is not very frequent on our shores; nor ever seen southward except in very severe winters. It is seldom met with on land, being for the most part on the open sea, diving for fish, which it does with great agility, and flies high and well. It is common in Iceland and Greenland, where it breeds, and at the time frequents the fresh waters. It is plentiful in Norway, and all along the arctic coasts, as far as the river Ob, in the Russian dominions. The Barabrinzians tau the breasts of this and other water fowls, whose skins the women prepare in such a manner as to preserve the down upon them; and sewing a number of them together, their husbands sell them, to make pellises, caps, &c. Garments made of these are very warm, never imbibing the least moisture; and are more lasting than could be imagined. They are also met with in the lakes of Hudson's Bay. The natives of Greenland use the skins for clothing. The Indians about Hudson's Bay adorn their heads with circlets of their feathers, and call the birds *athinue moqua*. As they are seldom seen on the sea-coasts, but chiefly among the lakes, they are called by the Indians inland loons.

6. *C. immer*, or the ember goose, is superior in to a common goose. The head is dusky; the back, coverts of the wings, and tail, clouded with lighter and darker shades of the same. The primaries and tail are black; the under side of the neck spotted with dusky spots; the breast and belly silvery; the legs black. They inhabit the seas about the Orkneys; but in severe winters visit the southern parts of Great Britain. They are also found in Iceland, and most parts of northern Europe, in Kamtschatka, and Switzerland, particularly on the lake Constance,

where it is known by the name of fluder. It is said to dive well, and to rise at an amazing distance from the place where it plunged. The female makes her nest among the reeds and flags, and places it in the water; so that it is continually wet. They are difficult to be taken, either on land or swimming on the water; but are often caught under the water, by a hook baited with small fish, its usual food.

7. *C. niger*, the grylle, or black guillemot, is in length fourteen inches, in breadth twenty-two; the bill is an inch and a half long, strait, slender, and black; the inside of the mouth red; on each wing is a large bed of white, which in young birds is spotted; the tips of the lesser quill-feathers, and the coverts of the wings, are white; the rest of the plumage is black. In winter it is said to change to white; and a variety spotted with black and white is not uncommon in Scotland. The tail consists of twelve feathers; the legs are red. These birds are found on the Bass Isle in Scotland; in the island of St. Kilda; on the rocks of Llandidno, in Caernarvonshire, and, as Mr. Ray imagines, in the Farn Islands off the coast of Northumberland. Except in breeding time they keep always at sea; and are not easily shot, diving at the flash of the pan. The Welsh call this bird *cascan longur*, or 'the sailor's hatred,' from a notion that its appearance forbodes a storm. It visits St. Kilda in March; makes its nest far under the ground; and lays a gray egg, or, as Stellar says, whitish and spotted with rust, and speckled with ash-color.

8. *C. sinensis*, the Chinese diver, described by Mr. Latham. The size is uncertain, but in the drawing the length was fourteen inches. The bill is dusky; irides ash color: the upper parts of the head, neck, body, wings, and tail, dusky greenish brown; the middle of the feathers much darker: the fore part of the neck the same, but considerably paler: chin pale rufous: breast and under parts of the body pale rufous white, marked with dusky rufous spots: the quills and tail are plain brown; the last short: legs ash-color.

9. *C. stellatus*, the speckled divers, a species less than the Chinese, weighs two pounds and a half, and is twenty-seven inches in length, and three feet nine inches in breadth. The bill is three inches long, bending upwards; and is of a pale horn color; the top of the upper mandible dusky; the head is dusky, dotted with gray: hind part of the neck plain dusky; the sides under the eye, the chin, and throat, white; fore part of the neck very pale ash-color; back dusky, marked with oval spots of white; sides of the breast and body of the same, but smaller; the spots on the tail and rump minute; breast and under part white; quills dusky; legs brown; webs and claws pale. This bird is pretty frequent in England, on the Thames, where it is called by the fishermen sprat loon, being often seen in vast numbers among the shoals of that fish, diving after them, and often approaching very near the boats while fishing. It is common about the Baltic, the White Sea, and Kamtschatka. It lays two eggs in the grass, on the borders of lakes near the sea. They are exactly oval, the size of those of a goose, dusky, marked with a few black spots. These birds are also frequent about the

fish ponds of France. They visit New York in winter, but return very far north to breed.

9. *C. troilus*, the troile, or foolish guillemot, weighs twenty-four ounces; its length is seventeen inches, the breadth twenty-seven and a half; the bill is three inches long, black, straight, and a harp pointed; near the end of the lower mandible is a small process; the inside of the mouth yellow; the feathers on the upper part of the tail are short and soft, like velvet; from the eye to the hind part of the head is a small division of the feathers. The head, neck, back, wings, and tail, are of a deep mouse-color; the tips of the lesser quill-feathers white; the whole under part of the body is pure white; the sides under the wings marked with dusky lines. Immediately above the thighs are some long feathers that curl over them. The legs are dusky. They are found in amazing numbers on the high cliffs of the British coasts, and appear at the same time with the auk. Though they are shot at, and see their companions killed, they will not quit the rock. They lay only one egg, which is very large; some are of a fine pale blue; others are white, spotted or elegantly streaked with lines crossing each other. They continue about the Orkneys the whole winter. The chief places they breed in are the isle of Priestholm, near Anglesey; on a rock called Godreve, near St. Ives; the Farn isles, and the cliffs about Scarborough. They are also found in most of the northern parts of Europe, at Spitsbergen, the coast of Lapland, and along the icy sea quite to Kamtschatka.

COMA, *n. s.* } Κῶμα. A morbid dispo-

COMATOSE, *adj.* } sition to sleep; a lethargy; lethargic; sleepy to a disease.

Our best castor is from Russia; the great principal use whereof, is in hysterical and *comatose* cases. *Grew.*

COMA BERENICES, Berenice's hair, in astronomy a constellation of the northern hemisphere, composed of unformed stars between the Lion's tail and Bootes. This constellation is said to have been formed by Conon, an astronomer, to console Berenice, the queen of Ptolemy Evergetes for the loss of a lock of her hair, which had been stolen out of the temple of Venus, where she had dedicated it on account of a victory obtained by her husband.

COMA SOMNOLENTUM, is when the patient continues in a profound sleep; and, when awaked, immediately relapses, without being able to open his eyes.

COMACCHIO, or COMACHIO, a town of Italy, in the ci-devant duchy of Ferrara, and territory of the church, afterwards included in the Italian republic, and department of the lower Po. It is situated in a marshy country called the Valley of Comachio, the see of a bishop, suffragan of Ravenna. It is twenty-seven miles south-east of Ferrara, forty south of Venice, and fourteen north of Ravenna.

COMART, *n. s.* This word, which we have only met with in one place, seems to signify treaty; article; from *con* and *mart*, or market.

By the same *comart*,

And carriage of the articles designed,

His fell to Hamlet. *Shakspeare. Hamlet.*

COMARUM, marsh-cinquefoil, a genus of the polyginia order, and icosandria class of plants, natural order thirty-fifth, senticosæ: *cal.* decemfid; the petals five, less than the calyx: receptacle of the seeds ovate, spongy, and persisting. There is but one species, a native of Britain. It rises about two feet high, and bears fruit somewhat like that of the strawberry. It grows naturally in bogs, and the root dyes a dirty red. The Irish rub their milking pails with it, and it makes the milk appear richer and thicker. Goats eat the herb; cows and sheep are not fond of it; horses and swine refuse it.

COMATE, *n. s.* Con and mate. Companion.

My *comates* and brothers in exile.

Shakspeare. As You Like It.

COMB in the end, and COMP in the beginning, of names, seem to be derived from the British *kum*, which signifies a low situation.

COMB, in Cornish, signifies a valley, and had the same meaning anciently in the French tongue.

COMB, *n. s.* Ang.-Sax. *camb*; κόμμη. An instrument to separate and adjust the hair.

———— but well wist I,

It was of Venus (redily)

This temple;—for in priesture

I sawe anone right, hire figure

Naked yfletyng in a se;

And also on hire hedde parde,

Hire rosy garlande white and redde;

And hire *combe* for to *kembe* hire hedde;

Hire doves; and Cupido

Hire blinde sonne; and Vulcano,

That in his face ywas full broune.

Chaucer's House of Fame.

There on a day a noble youthful knight,

Seeking adventures in the salvage wood,

Did by great fortune get of her the sight,

As she sat careless by a cristall ffood

Comb'ing her golden lockes, as seemed her good.

Spenser.

By fair Ligea's golden *comb*,

Wherewith she sits on diamond rocks,

Steeking her soft alluring locks. *Milton.*

I made an instrument in fashion of a *comb*, whose teeth, being in number sixteen, were about an inch and a half broad, and the intervals of the teeth about two inches wide. *Newton.*

The top or crest of a cock, so called from its pectinated indentures.

Cocks have great *combs* and spurs, hens little or none. *Bacon.*

High was his *comb*, and coral-red withal,

With dents embattled like a castle-wall. *Dryden.*

The cavities in which the bees lodge their honey. Perhaps from the same word which makes the termination of towns, and signifies hollow or deep.

What do ye honey-*combe*! sweet Alisoun?

My faire birde! my swete sinamore!

Awaketh lemman min! and speketh to me.

Chaucer's Canterbury Tales.

The pretty bees, with daily paines contrive
Their curious *combes*, and from the flowry fields,
Doe bring that pleasant sweetness to their hive
Which nectar and ambrosiac dainties yield.

Geo. Wickers.

This in affairs of state,

Employed at home, abides within the gate,

To fortify the *combs*, to build the wall,
To prop the ruins, lest the fabric fall.

Dryden's Virgil.

To *Comb*, *v. a.* From the noun. To divide,
and clean, and adjust the hair with a comb.

Her care shall be

To *comb* your noddle with a three-legged stool.

Shakespeare.

Divers with us, that are grown grey, and yet would
appear young, find means to make their hair black, by
combing it, as they say, with a leaden *comb*, or the
like.

She with ribbons tied

His tender neck, and *combed* his silken hide.

Dryden's Æneid.

There was a sort of engine, from which were ex-
tended twenty long poles, wherewith the man-moun-
tain *combs* his head.

Swift.

To lay anything consisting of filaments smooth,
by drawing through narrow interstices; as, to
comb wool.

COMB-BRUSH, *n. s.* Comb and brush. A brush
to clean combs.

COMB-MAKER, *n. s.* Comb and maker. One
whose trade is to make combs.

This wood is of use for the turner, engraver, carver,
and *comb-maker*.

Mortimer's Husbandry.

COMB-MAKING. The common sorts of combs
are generally made of the horns of bullocks, or of
elephants' and sea horses' teeth; some are made
of tortoise-shell; others of box, holly, and other
hard woods.

Bullocks' horns are prepared for being manu-
factured into combs by the tips being sawn off,
after which they are held in the flame of a wood
fire, till they become nearly as soft as leather.
In this state they are split open on one side and
pressed in a machine between two iron plates,
then plunged into a trough of water, whence they
come out hard and flat. When the horn is cut
to the size intended for the required combs,
several pieces are laid upon a pair of tongs,
adapted to the business, over a fire, made chiefly
of joiners' shavings, to soften them. They are
frequently turned, and, when sufficiently soft, are
put into a vice and screwed tight to complete the
flattening. When this process is finished, the
horns are perfectly flat and hard; they are then
given to a man who shaves, planes, or scrapes
off the rough parts with a knife, similar in shape
to one used by coopers, having two handles,
which the comb-maker works from him, across
the grain of the horn, from one end of the in-
tended comb to the other. When both sides are
perfectly smooth, it is delivered to the person
who cuts the teeth.

This workman fastens it with wedges, by that
part meant for the back, into an instrument
called a clam. The clam has a long handle,
which the workman places under him as he sits,
by which means he renders the object of his work
firm and steady, and he has, at the same time,
both hands at liberty to be employed in the
operation. The cutting of the teeth is com-
menced by a double saw, of which each blade is
something like the small one with which joiners
and cabinet-makers cut their fine work: with
this he forms the teeth. As this instrument
leaves the work square, and rather in a rough

state, particularly in the inside edge of each
tooth, it is followed by another about the size
and shape of a case knife, having teeth like a
file, on each flat side. After this, two others of
the same shape, but each finer cut than the other,
follow. One stroke, on each side of the comb, is
then given by a rasping tool, which is used to
take off any roughness that may remain on the
sides of the teeth: it is now delivered to another
operator, who polishes it with rotten-stone and
oil, applying them with a piece of buff leather.

The process used for making ivory combs, is
nearly the same as that just described, excepting
that the ivory is first sawn into thin slices. That
imported from Ceylon is preferred, as being
less liable to turn yellow, by exposure to the
atmosphere. The whiteness which ivory ac-
quires, depends chiefly on the degree of dryness
which it has attained. When yellow, its gelati-
nous matter is altered by the air, and appears
combined with the oxygen of the atmosphere.
Heat cannot be made use of for making ivory
pliant, though it is rendered softer by being ex-
posed to that agent. It is, as we have observed,
divided by the saw, and, for very delicate work,
the operation is sometimes performed under
water, to prevent its being heated or rent by the
action of the tool. It is polished with pumice
stone and tripoli. Ivory has been said to be-
come soft by being placed in mustard, but both
ivory and bone are softened by being immersed
in an alkaline lye made of soda and quick-lime.

We shall now give some account of the meth-
od of cutting combs adopted by Mr. William
Bunday, of Camden town, who obtained his
Majesty's letters patent for the invention. The
term of his exclusive privilege being complete, it
is open to any manufacturer to make what use
he pleases of the discovery. It appears at first
sight to be a singular circumstance, that in a
country famous for its attention to mechanical
processes, the teeth of ivory combs, should be
cut one stroke after the other, by the human
hand, assisted by no other tool than a pair of
saws rudely fastened in a wooden back, and kept
asunder, by means of a small slip of wood.
With these rough implements, however, it is,
that the very delicate superfine ivory combs,
containing from fifty to sixty teeth in an inch,
are manufactured. It may readily be conceived,
that the imaginations of mechanical men must
have been employed in an attempt to solve the
practical problem of constructing a machine,
which, without skill in the agent or first mover,
might perform all that men, converted by prac-
tice into a kind of living machines, are capable
of doing, but with less cost, or greater product,
in proportion as it is easier to maintain the one
than the other. Accordingly it is not difficult
to find traces of attempts of this kind during the
last forty years, in the traditions of our manu-
facturing towns and counties. From what causes
their failure may have arisen, since none of them
have been established to supersede the old prac-
tice, is not easy to discover, but it is certain that
Mr. Bunday's machine is the first and only one
which has yet appeared at the patent office. Its
construction is as follows:—

An iron fly-wheel of three feet in diameter, is

moved by a crank and treadle, or by any other power or means of application. On the same axis is a wheel or pulley, of fifteen inches diameter, which, by a gut, drives another pulley of nine inches attached to a puppet head above, and shears resembling those of a common foot lathe. An arbor is driven by this upper wheel, in the same manner as work is thrown round between centres before the mandrell in the common lathe. On the arbor are fixed a number of circular cutters, about two inches diameter, corresponding to the notches intended to be cut in the combs. These cutters are all of a thickness, and have brass washers between them, and also from another arbor in a frame there are steel pieces, called guiders, which stand between the cutters, and keep them regularly asunder, just above the place where the comb enters.

The comb is held, by a plate and two screws, upon the top of a block or carriage, which runs off and on by means of a platform, and dovetail upon the lathe bed. The comb moves in its own plane, right onward, to the centre or axis of the cutters, and the carriage is driven by a screw of ten threads in the inch, into which a knife edge from the carriage falls, instead of a nut. On the extremity or tail of the screw is fixed a spur wheel of thirty teeth driven by an endless screw, the arbor of which last is of course parallel to the arbor of the cutters. It is driven by a pulley of six inches concentric with the cutting arbor, and itself has a pulley of three.

Hence if the great wheel be moved once round, per second, the arbor will revolve $\frac{1}{5}$ times and the endless screw arbor $\frac{3}{5}$ times but from the dimensions of the screw, thirty revolutions of the endless screw make $\frac{1}{5}$ inch of the tooth, or 150 revolutions make $\frac{1}{2}$ inch. With this length of tooth, the great wheel will revolve forty-five times, and the cutting arbor seventy-five times. One side of the comb will therefore be cut in three quarters of a minute. The combs are pointed by applying them to an arbor, clothed with cutters, with chamfered edges and teeth $\frac{1}{20}$ inch deep: they are so applied by the hand. This arbor is driven by a wheel on the crank axis. The cutters are made of tempered steel, as are also the guides, the teeth of the cutters are set so as to clear the back or following part from the friction in the cut.

The cutters, the cutter washers, the guides, and the guide washers, are all ground flat and thin, upon a brass plate, in the same manner as optical work is ground; during which operation the piece is retained again on an upper movable plate, of its own size, by means of a circular rim or edge which is adjustable by screws, so as to form a deeper or shallower cell, as may be required. The guides are one-twentieth part thinner than the washers of the cutters, and the guide washers are somewhat thicker than the cutters, and there are grooves in the sides of the guides that the teeth of the cutters may pass clear, notwithstanding their side sets.

The writer had an opportunity of examining one of the cutters of this artist, which had been given by him to a friend. It was beautifully wrought, very uniform in its thickness, which was about the $\frac{1}{100}$ of an inch, and the sets of the

teeth, which seemed to have been affected by the blow of a punch on every other tooth, was extremely accurate: it was not perfectly flat, but had that kind of flexure which workman call a buckle. He also saw an ivory comb of forty teeth in the inch, which was very uniform, and equal to the best work done by hand, except that the cut seemed too wide.

It appears to be placed beyond a doubt, that combs may really be cut in this way; but whether to advantage must depend on the cast and durability of the cutters, which, it is to be feared, may be bended and spoiled in a course of work, by their incessant friction between the guides. It may also be remarked, that they cannot be taken off the arbor to sharpen or repair, and be put on again without changing the degree of fineness in the comb they will cut. For if we suppose an error of one-thousandth of an inch in grinding or callipering the cutters and washers, or in the different force of screwing them together on the arbor; this will make a difference of one-third of an inch, or the breadth of seventeen teeth in a superfine comb, No. 6, which if coarser would bring it more than half way to the sort called dandriff, or, if finer, would equal the box-comb. Besides which a much less difference would totally destroy the agreement or fitting between cutting and pointing. A more particular account of the patent invention, with engravings, may be found in the *Repertory of Arts* for the year 1796.

Tortoise-shell combs, as they are called, are very much used. It has, however, been properly observed, that the hard strong covering which encloses tortoises, and which is used on these occasions, is improperly denominated a shell; being of a bony contexture, but covered on the outside with scales, or rather plates of a horny substance. There are two general kinds of tortoises, viz. the land and the sea tortoise; the latter is divided into many distinct species, but the *testudo-imblicata* of Linnaeus alone furnishes that beautiful shell so much admired in European countries. This consists of thirteen leaves or scales, eight of them flat, and five bent. The best tortoise-shell is thick, clear, transparent, of the color of antimony, sprinkled with brown and white.

Tortoise-shell, like horn, becomes soft in a moderate heat, as that of boiling water, so as to be pressed in a mould, into any form, the shell being previously cut into plates of a proper size. Two plates may likewise be united into one by heat and pressure, the edges being thoroughly cleaned, and made to fit close to one another. The tortoise-shell is conveniently heated for this purpose by applying a hot iron above and beneath the juncture, with the interposition of a wet cloth, to prevent the shell from being scorched by the irons; these irons should be pretty thick that they may not lose their heat before the union is effected.

Tortoise-shell being in so much request, many methods have been invented for the purpose of staining horn so as to imitate tortoise-shell; of which the following is one:—The horn to be dyed, being first pressed into a flat form, is to be spread over with a kind of paste made of two

parts of quick lime and one of litharge, brought into a proper degree of consistency with soap-lee. This paste must be put over all the parts of the horn except such as are intended to be left transparent, to give it a nearer resemblance to tortoise-shell; the horn must remain in this state till the paste be quite dry, when it is to be rubbed off. It requires a considerable share of taste and judgment to dispose the paste in such a manner as to form a variety of transparent parts, of different magnitudes and figures, to look like nature. Some parts are, by a neat process, rendered semi-transparent, which is effected by mixing whitening with a part of the paste, to weaken its operation in particular places; by this means spots of a reddish-brown will be produced, so as greatly to increase the beauty of the work. Horn thus dyed is manufactured into combs, which are frequently sold for real tortoise-shell: we shall now add two or three other directions on subjects connected with this business.

To make horn soft.—Take wood-ashes and quick lime; of these make a strong lee, and filter it clear, boil the shavings or chips of horn therein, and they will soon be reduced to a paste, this may be colored, and cast into any form required.

To prepare horn leaves in imitation of tortoise-shell.—Take of quick lime one pound, and litharge of silver eight ounces, mix them into a paste with urine, and make spots with it, in what form or shape you please, on both sides of the horn; when dry, rub off the powder, and repeat this as many times as necessary. Then take vermilion, prepared with size, lay it all over one side of the horn, as also on the wood to which you intend to fasten it. For raised work, form the horn in a mould of any shape, and when dry give it color with the aforesaid paste and vermilion; then lay clear glue, both on the horn and the wood on which it is to be fixed, and close it together. This work is to be done in rather a warm place: it is then to stand all night; the roughnesses are to be cut or filed off; and the horn polished with tripoli and linseed oil. Work finished in this manner is well adapted for ladies' combs.

Another method of imitating tortoise-shell with horns.—Take of nitrous acid two ounces, and of fine silver one drachm; let the silver be dissolved, and, having spotted or marbled your horn with wax, strike the solution over it; let it dry of itself, and the horn will be, in those places which are free from wax, of a brown or black color.

To dye ivory green, to be used as combs.—A green dye may be given to ivory, by steeping it in nitrous acid, tinged with copper or verdigris, or in two parts of verdigris and one of sal ammoniac, ground well together, with strong white wine vinegar poured on them; and by converting the nitrous acid into aqua regia, by dissolving a fourth part of its weight of sal ammoniac in it, ivory may be stained of a fine purple color.

To dye ivory, &c. with other colors.—Ivory, bone, horn, and other substances, adapted to the manufacture of combs may be stained yellow, by boiling them first in a solution of one pound of alum in two quarts of water, and then boiling

them in a solution of turmeric root. Ivory &c. may be stained blue, by first staining it green, and then dipping it in a solution of pearl-ashes, made strong, and boiling hot. It may be accomplished also by boiling in the tincture of indigo, prepared by the dyers, and afterwards in a solution of tartar, made by dissolving three ounces of white tartar, or cream of tartar in a quart of water.

Combs are sometimes set with brilliant stones, pearls, and even diamonds; and some are studded with cut steel. They are of various shapes, and are used to fasten up the hair, when ladies dress without caps. Of course combs may be had of all prices from a few pence to almost any sum. Journeymen comb-makers will earn from 25s. to two guineas per week.

COMBAT, *v. n., v. a. & n. s.* } Fr. *combat-*
CO'MBATANT, *n. s.* } *tre; combat-*
To fight, generally in a duel or hand to hand, but sometimes used for battle; it is also employed, figuratively, in the same sense with regard to matters of opinion. It is not strictly synonymous with to oppose; it is true one always opposes in combating, but not vice versa; a person's positions are combated, his interests are opposed.

But ere they could procede unto the place

Where he abode, themselves at discord fell,
With cruel combat joynd in middle space,
With horrible assault, and fury fell

They heaped huge strokes the scorned life to quell.

Spenser.

The noble *combat* that, 'twixt joy and sorrow, was fought in Paulina! She had one eye declined for the loss of her husband, another elevated that the oracle was fulfilled.

Shakespeare.

Pardon me, I will not *combat* in my shirt. *Id.*

So frowned the mighty *combatants*, that he'll

Grew darker at their frown. *Milton's Paradise Lost.*

Two planets rushing from aspect malign

Of fiercest opposition in mid sky,

Should *combat*, and their jarring spheres confound.

Id.

Who, single *combatant*,

Duelled their armies ranked in proud array.

Himself an army.

Id. Agonistes.

Old Waller trumpet-general swore he'd write

This *combat* truer than the naval fight. *Marvell.*

He with his sword unsheathed, on pain of life.

Commands both *combatants* to cease their strife.

Dryden.

The *combat* now by courage must be tried. *Id.*

Their oppressors have changed the scene, and *combated* the opinions in their true shape.

Decay of Piety.

Love yields at last, thus *combated* by pride,

And she submits to be the Roman's bride.

Granville.

But now so variously the *combat* bleeds

That Fame, though all her tongues should give them breath,

Could not express the bold and warlike deeds

Of warriors ranging through this field of death. *Gay.*

The trials by single *combat* gradually obtained superior credit and authority, among a warlike people, who could not believe, that a brave man deserved to suffer, or that a coward deserved to live.

Gibbon.

The mariner not vainly brave

Combats the storm, and rides the wave,

To rest at last on shore.

Beattie.

To *combat* may be glorious, and success
Perhaps may crown us, but to fly is safe. *Cowper*.

COMBAT, in our ancient law, was a formal trial of some doubtful cause or quarrel, by the swords or bastions of two champions. The last trial of this kind in England was between Donald lord Ray appellant, and David Ramsay, esq. defendant, when, after many formalities, the matter was referred to the king's pleasure. See BATTLE.

COMBER, *n. s.* From comb. He whose trade it is to disentangle wool, and lay it smooth for the spinner.

COMBER (Thomas), a learned English divine, born at Shermaunbury, in Sussex, in 1575. He was the twelfth child of an ancient family, and, surviving all his elder brothers, inherited the estate. He was educated at Horsham school, from whence he removed to Trinity College Cambridge, where he made a great progress in all kinds of learning, particularly in the Oriental Languages. In 1596 he became a fellow of his college, and in 1598 took his master's degree. In 1607 he obtained leave to travel, and resided three years in France, where he contracted an intimacy with the learned Dr. Moulin. He took the degree of D. D. in 1616, and about the same time became chaplain to the king. Charles I. sent him to Scotland to confer with some of the presbyterian divines about the form of church government, and, in 1630, he was promoted to the deanery of Carlisle, and the year following appointed master of Trinity College; at which time he also served the office of vice-chancellor. As master of his college he acquired a great and deserved reputation; but, soon after the commencement of the rebellion, he was deprived of that and of his deanery. He was also imprisoned for his loyalty and otherwise ill-treated, but bore all his sufferings with calm resignation. He died in 1654, and was buried in the church of St. Botolph, Cambridge.

COMBER (Thomas), an eminent divine of the same family with the preceding, born at Westerham in Kent in 1645, educated at Cambridge; created D. D. and after several preferments in the church made dean of Durham. He was chaplain to Anne princess of Denmark, and to king William and queen Mary. He wrote 1. A Scholastical History of the Primitive and General use of Liturgies. 2. A Companion to the Altar. 3. A brief Discourse upon the offices of Baptism, Catechism, and Confirmation. He died in 1699, aged fifty-five.

COMBINE, *v. a. & v. n.* } Lat. *con* and
COMBINATE, *adj.* } *binus*, signifies ty-

COMBINATION, *n. s.* } ing two into one.
Fr. *combiner*. The first idea therefore is union of bodies, or qualities; commixture; conjunction: the next is copulation of ideas in the mind. As a term of science, combination is used in mathematics to denote the variation or alteration of any number of quantities, letters, sounds or the like, in all the different manners possible. Thus the number of possible changes or combinations of the twenty-four letters of the alphabet, taken first two by two, then three by three, &c. amount to 1,391,724,288,887,252,999,425,128,493,402,200. Its general applications are the following: to a union or league of private

persons for some certain purpose; it is now used in an ill sense, in those associations which respect the interests of the few to the injury of the many. When applied to things combination is an arbitrary action. Thus it differs from association. Association is a natural union, but combinations are formed either by design or accident; nothing will associate but what harmonises; things the most opposite in their nature are combined together. The verb signifies to join together; to keep in union; to agree; to accord; to settle by compact; to join words or ideas together; the opposite of analyse.

These natures, from the moment of their first combination, have been and are for ever inseparable.

Hooker.

This cunning cardinal

The articles of the combination drew.

As himself pleased. *Shakspeare. Henry VIII.*

God, the best maker of all marriages,

Combine your hearts in one, your realms in one.

Id.

Honour and policy, like unsevered friends

I th' war, do grow together: grant that, and tell me

In peace what each of them by th' other loses,

That they combine not there? *Id. Coriolanus.*

She lost a noble brother; with him the sinew of her fortune, her marriage dowry: with both her combine husband, this well-seeming Angelo.

Id. Measure for Measure.

My heart's dear love is set on his fair daughter;

As mine on hers, so hers is set on mine,

And all combined, save what thou must combine

By holy marriage. *Id. Romeo and Juliet.*

Combine together 'gainst the enemy;

For these domestic and particular broils

Are not the question here. *Id. King Lear.*

They aim to get all to their own will and power, under the disguises of holy combinations.

King Charles.

Let us not then suspect our happy state,

As not secure to single or combined.

Milton's Paradise Lost.

Ingratitude is always in combination with pride and hard-heartedness.

South.

Friendship is the cement which really combines mankind.

Government of the Tongue.

You with your foes combine,

And seem your own destruction to design.

Dryden's Aurengzebe.

They never suffer any ideas to be joined in their understandings, in any other or stronger combination than what their own nature and correspondence give them.

Locke.

Resolution of compound bodies by fire, does not so much enrich mankind as it divides the bodies; as upon the score of its making new compounds by new combinations.

Boyle.

Where the tall oak his spreading arms entwines,
And with the beech a mutual shade combines.

Gay.

'Tis infamy to serve a nag,

Cats are thought imps, her broom a nag,

And boys against our lives combine

Because 'tis said your cats have nine. *Id.*

Wise, beauteous, good! O every grace combined

That charms the eye, and captivates the mind!

Beattie.

The cry of the people in cities, and towns though unfortunately (from a fear of their multitude and combination), the most regarded, ought in fact to be the least regarded, on the subject of monopoly. *Burke*

Before the time of Dryden those happy combinations of words which distinguish poetry from prose, had been rarely attempted. *Johnson.*

COMBINATION, in chemistry, signifies the union of two bodies of different natures, from which a new compound body results. For example, when an acid is united with an alkali, we say that a combination betwixt these two saline substances takes place; because from this union a neutral salt results, which is composed of an acid and an alkali.

COMBINATIONS, in the mathematics, I. In all combinations, if from an arithmetical decreasing series, whose first term is the number out of which the combinations are to be formed, and whose common difference is 1, there be taken as many terms as there are quotients to be combined, and those terms be multiplied into each other: and if from the series 1, 2, 3, 4, &c. there be taken the same number of terms, and they be multiplied into each other, and the first product be divided by the second, the quotient will be the number of combinations required. Therefore, if you would know how many ways four quantities can be combined in seven, multiply the first four terms of the series, 7, 6, 5, 4, &c. together, and divide the product, which will be 840, by the product of the first four terms of the series, 1, 2, 3, 4, &c. which is 24, and the quotient 35 will be the combination of 4 in 7.

II. In all permutations, if the series 1, 2, 3, 4, &c. be continued to as many terms as there are quantities to be changed, and those terms be multiplied into each other, the product will be the number of permutations sought. Thus, if you would know how many permutations can be formed with five quantities, multiply the terms 1, 2, 3, 4, 5, together, and the product 120 will be the number of all the permutations.

COMBINATIONS, PROBLEMS IN. I. To find the number of changes that may be rung on twelve bells. It appears by the second aphorism, that nothing more is necessary here than to multiply the numbers from 1 to 12 continually into each other, and the last product will be the number sought, viz. 479,001,600. II. Suppose the whole twenty-four letters of the alphabet to be written so small, that no one of them shall take up more space than the hundredth part of a square inch: to find how many square yards it would require to write all the permutations of the twenty-four letters in that size? By following the same method as in the last problem, the number of permutations of the twenty-four letters will be found to be

62,044,840,173,323,943,936,000.

Now the inches in a square yard being 1296, that number multiplied by 100 gives 129,600, which is the number of letters each square yard will contain; therefore if we divide

62,044,840,173,323,943, 936,000

by 129,600, the quotient, which is

478,741, 050,720,092,160

will be the number of yards required to contain the above-mentioned number of permutations. But, as all the twenty-four letters are contained in every permutation, it will require a space twenty-four times as large; that is,

11,489,785,217,282,211,840.

Now the number of square yards contained on the surface of the whole earth is but

617,197,435,008,000,

therefore it would require a surface 18,620 times as large as that of the earth to write all the permutations of the twenty-four letters in the size above mentioned. III. To find how many different ways the eldest hand at piquet may take in his five cards. The eldest hand having twelve cards dealt him, there remain twenty cards, any five of which may be in those he takes in, consequently, we are here to find how many ways five cards may be taken out of twenty. Therefore, by aphorism I. if we multiply 20, 19, 18, 17, 16, into each other, which will make 1860480, and that number be divided by 1, 2, 3, 4, 5, multiplied into each other, which make 120, the quotient, which is 15504, will be the number of ways five cards may be taken out of twenty. From hence it follows that it is 15,503 to 1, that the eldest hand does not take in any five certain cards. IV. To find out the number of deals a person may play at the game of whist, without ever holding the same cards twice. The number of cards played with at whist being 52, and the number dealt to each person being 13, it follows, that by taking the same method as in the last experiment, that is, by multiplying 52 by 51, 50, &c. so on to 41, which will make

3,954,242,643,911,239,680,000,

and then dividing that sum by 1, 2, 4, &c. to 13, which will make 6,227,020,100, the quotient, which is 635,013,559,600 will be the number of different ways thirteen cards may be taken out of fifty-two, and consequently the number sought. We add the following table of combinations, or the arithmetical triangle.

A

1 Rank	1	B																						
2		2.	1																					
3			3.	3.	1																			
4				4.	6.	4.	1																	
5					5.	10.	10.	5.	1															
6						6.	15.	20.	15.	6.	1													
7							7.	21.	35.	35.	21.	7.	1											
8								8.	28.	56.	70.	56.	28.	8.	1									
9									9.	36.	84.	126.	126.	84.	36.	9.	1							
10										10.	45.	120.	210.	252.	210.	120.	55.	10.	1					
11											11.	55.	165.	380.	462.	462.	330.	165.	45.	11.	1			
12												12.	66.	220.	495.	792.	924.	702.	495.	220.	66.	12.	1	b

The construction of this table is very simple. The line *Aa* consists of the first twelve numbers. The line *Ab* consists everywhere of units; and second term 3, of the line *Bc*, is composed of the two terms 1 and 2 in the preceding rank: the third term 6, in that line, is formed of the two terms 3 and 3 in the preceding rank: and so of the rest; every term, after the first, being composed of the two next terms in the preceding rank: and by the same method it may be continued to any number of ranks. To find by this table how often any number of things can be combined in another number under thirteen, as suppose five cards out of eight; in the eighth rank look for the fifth term, which is 56, and that is the number required. Though we have shown in the foregoing problems the manner of finding the combination of all numbers whatever, yet as this table answers the same purpose for small numbers, by inspection only it will be found useful on many occasions; as will appear by the following examples. I. To find how many different sounds may be produced by striking on a harpsichord two or more of the seven natural notes at the same time.

1. The combinations of two in seven, by the foregoing triangle, are . . . 21
2. The combinations of 3 in 7 are . . . 35
3. The combinations of 4 in 7 are . . . 35
4. The combinations of 5 are . . . 21
5. The combinations of 6 are . . . 7
6. The seven notes all together once . . . 1

Therefore the number of all the sounds will be . . . 120

II. Take four square pieces of pasteboard of the same dimension, and divide them diagonally, that is, by drawing a line from two opposite angles, as in the diagram, into eight triangles;

paint seven of these triangles with the primitive colors; red, orange, yellow, green, blue, indigo, violet, and let the eighth be white. To find how many chequers or regular four-sided figures, different either in form or color, may be made out of those eight triangles. First, by combining two of those triangles, there may be formed either the triangular square A, or the inclined square B called a rhomb. Secondly, by combining four of the triangles, the large square C may be formed; or the long square D, called a parallelogram. The first two squares consisting of two parts out of eight, each of them may, by the eighth rank of the triangle, be taken twenty-eight different ways, which makes fifty-nine. And the last two squares, consisting of four parts,

may each be taken by the same rank of the triangle seventy times, which makes . . . 140
To which add the foregoing number . . . 56

And the number of the different squares that may be formed of the eight triangles, will be . . . 196

III. A man has twelve different sorts of flowers, and a large number of each sort. He is desirous of setting them in beds or flourishes in his parterre. Six flowers in some, seven in others, and eight in others, so as to have the greatest variety possible; the flowers in no two beds to be the same. To find how many beds he must have:

1. The combinations of 6 in 12, by the last rank of the triangle, are . . . 924
2. The combinations of 7 in 12 are . . . 792
3. The combinations of 8 in 12 are . . . 495

Therefore the number of beds must be 2211

IV. To find the number of chances that may be thrown on two dice. As each die has six faces, and as every face of one die may be combined with all the faces of the other, it follows that 6 multiplied by 6, that is 36, will be the number of all the chances; as is also evident from the following table:

Points.	No. of Chances.	No. of Points.
2 1-1	1	2
3 2-1 1-2	2	6
4 2-2 3-1 1-3	3	12
5 4-1 1-4 3-2 2-3	4	20
6 3-3 5-1 1-5 4-2 2-4	5	30
7 6-1 1-6 5-2 2-5 4-3 3-4	6	42
8 4-4 6-2 2-6 5-3 3-5	5	40
9 6-3 3-6 5-4 4-5	4	36
10 5-5 6-4 4-6	3	30
11 6-5 5-6	2	22
12 6-6	1	12
	36	252

It appears by this table, 1. That the number of chances for each point continually increases to the point of 7, and then continually decreases till 12; therefore, if two points are proposed to be thrown, the equality, or the advantage of one over the other, is clearly visible. It is easy from hence to determine whether a bett proposed at hazard, or any other game with the dice, be advantageous or not; if the dice be true, which, by the way, is rarely the case for any long time together, as it is so easy for those that are possessed of a dexterity of hand to change the true dice for false. 2. The whole number of chances on the dice being 252, if that number be divided by 36, the number of different throws on the dice, the quotient is 7: it follows, therefore, that at every throw there is an equal chance of bringing seven points. 3. As there are thirty-six chances on the dice, and only six of them doublets, it is five to one, at any one throw,

against throwing a doublet. By the same method the number of chances upon any number of dice may be found; for if 36 be multiplied by 6, that product, which is 216, will be the chances on three dice; and if that number be multiplied by 6, the product will be the chances on four dice, &c. Among the different purposes to which the doctrine of combination may be applied, those of writing in cipher, and deciphering, hold a principal place. See the article CIPHER. And, upon the same principle, those who have ingenuity and leisure, may amuse themselves and their friends, by cards previously marked with letters or words; which, after shuffling and dealing in seeming confusion, and apparently by chance, surprise the company by producing a sublime sentiment, or paying a polite compliment to each person present.

COMBLESS, *adj.* From *comb.* Wanting a comb or crest.

What, is your crest a coxcomb?—

—A *combless* cock, so Kate will be my head.

Shakspeare.

COMB-MARTIN, a town in Devonshire, seated on the Bristol Channel, at the mouth of the Severn, from which it has an inlet that runs through the town, with a cove for landing boats. There are lead-mines near it, which formerly produced some silver ore. It has a market on Saturday, and a fair on Whitsun-Monday. It is seven miles east of Ilfracomb, and 202 west of London.

COMBOOCONAM, a neat town of the province of Tanjore, Hindostan, twenty miles N.N.E. from the city of Tanjore. It was formerly the capital of the Cholas, one of the most ancient of the Hindoo dynasties, from which, in latter times, the whole coast of Cholanundul (Coromandel) has taken its name: it contains many vestiges of its ancient splendor, and is chiefly, at present, inhabited by brahmins. Some of the tanks and pagodas are very fine, and the surrounding country is fertile and well cultivated.

COMBUST, *adj.*

Lat. comburo,

COMBUSTIBLE, *adj.*

combustum. The

COMBUSTIBLENESS, *n. s.*

first adjective is

COMBUSTION, *n. s.*

used in astronomy

and in astrology, but in what sense it is rather difficult to say. Milton alludes to planets that are combust, in the sense of their being obscured and out of sight by the brightness of the sun; and Chaucer represents it as synonymous with a bad aspect, or concealment from view. The general application is the same with the other derivatives, namely, having the quality of catching fire; susceptible of fire, aptness to take fire. Combustion is conflagration and consumption by fire. It is also used metaphorically for tumult, hurry, hubbub, bustle, hurly burly.

When a planet is not above eight degrees and a half distant from the sun, either before or after him, it is said to be *combust*, or in *combustion*. *Harris.*

And if I had, O Venus ful of mirth!

Aspects badde of Mars or of Saturne;

Or thou *combuste*; or let were in my birth;

Thy father pray—al thilke harm disturne,

Of grace, and that I glad ain maie tume,

For love of him thou lovedest in the shawe,

I mene Aden that with the bore was slawe.

Chaucer. Troilus and Cresside.

We boast our light; but if we look not wisely on the sun itself, it smites us into darkness. Who can discern those planets that are oft *combust*, and those stars of brightest magnitude that rise and set with the sun, until the opposite motions of those orbs bring them to such a place in the firmament where they may be seen evening and morning? *Milton.*

Mutual *combustions*, bloodsheds, and wastes may enforce them, through very faintness, after the experience of so endless miseries. *Hooker.*

Propheying with accents terrible,

Of dire *combustion*, and confused events,

New-hatched to the woeful time.

Shakspere. Macbeth.

Those cruel wars between the houses of York and Lancaster, brought all England into an horrible *combustion*. *Raleigh.*

Charcoals made out of the wood of oxycedar, are white, because their vapours are rather sulphureous than of any other *combustible* substance.

Browne's Vulgar Errors.

How much more of power,

Army against army, numberless to raise

Dreadful *combustion* warring, and disturb,

Though not destroy, their happy aactive seat!

Milton.

Sin is to the soul like fire to *combustible* matter; it assimilates before it destroys it. *South.*

They are but strowed over with a little penitential ashes; and will, as soon as they meet with *combustible* matter, flame out. *Deeuy of Piety.*

The future *combustion* of the earth is to be ushered in and accompanied with violent impressions upon nature. *Burnet.*

The flame shall still remain;

Nor, till the fuel perish, can decay,

By nature formed, on things *combustible* to prey.

Dryden.

But say, from whence this new *combustion* springs?

Id.

The comet moves in an inconceivable fury and *combustion*, and at the same time with an exact regularity. *Addison's Guardian.*

COMBUSTIO PECUNIE, the ancient way of trying mixed and corrupt money, by melting it down upon payments into the exchequer. In the time of king Henry II. a constitution was made, called the trial by combustion; the practice of which differed little or nothing from the present method of assaying silver. But whether this examination of money by combustion was to reduce an equation of money only to sterling, viz. a due proportion of alloy with copper, or to reduce it to pure fine silver, does not appear. On making the constitution of trial it was considered, that though the money did answer in number and weight, it might be deficient in value, because mixed with copper or brass, &c.

COMBUSTION, in phisic, has been defined, the operation of fire upon any inflammable substance, by which it smokes, flames, and is reduced to ashes. Dr. Ure describes it as the disengagement of heat and light which accompanies chemical combination. 'It is frequently,' he says, 'made to be synonymous with inflammation, a term which might be restricted, however, to that peculiar species of combustion in which gaseous matter is burned. Ignition is the incandescence of a body, produced by extrinsic means, without change of its chemical constitution.' There is no phenomenon in nature by which the attention

of philosophers has been more engaged, nor which has perplexed them more to account for, than this very common operation. To explain it, the most opposite and contradictory theories have been espoused; and, till very lately, science did not afford data sufficient to explain it in a rational manner. By former chemists it was supposed, that the parts of the combustible body itself were converted into fire. Accordingly, Sir Isaac Newton proposes it as a query, whether gross bodies and light are not convertible into one another! And many chemists of modern date, have determined this question in the affirmative, by maintaining that the light of the sun is, or contains, phlogiston. The interference of the air, however, in most cases of combustion known to us, proved a difficulty in this theory almost, if not totally, insurmountable; for if the fire proceed entirely from the combustible body, what occasion is there for any third substance distinct both from the fire and that body to produce combustion? This naturally excited a conjecture, that the fire by which the combustible body is consumed proceeds in reality from the air, and not from the body itself. And hence we see that Mr. Hutchinson's system of fire and air being convertible into one another, might have passed for a rational human theory, if he had not attempted to force it upon mankind as a divine revelation. The modern discoveries in acrology, however, have entirely disproved this hypothesis with regard to our atmosphere considered as a whole, at the same time that they point out the true method, as far as our faculties seem capable of comprehending it, by which this mysterious operation is performed.

It is now almost universally known, that the air we breathe is composed of two kinds of elastic fluids, only one of which contributes to the support of flame, as well as of animal life; and this part is found to be by far the least in quantity of the atmosphere we breathe. This kind of air, since its first discovery by Dr. Priestley, in 1774, has passed by the various names of dephlogisticated, empyreal, vital, and pure air, and is sometimes denominated oxygenous gas. It is computed from good observations, that among the various component parts of our atmosphere, there is about one-fourth, $\frac{2}{3}$ according to Mr. Scheele, or, according to Mr. Cavendish, one-fifth of this pure fluid contained in it; and to this small part alone is owing the combustion of inflammable bodies. Since the establishment of this important fact, several theories of combustion have been formed.

Dr. Crawford endeavours to account for combustion, upon the exploded doctrine of phlogiston. By a great number of ingenious experiments he has endeavoured to show, that bodies, which contain a large portion of phlogiston, possess but a small share of specific heat or fire; on the contrary, that those with a large share of this last, contain but little phlogiston; and lastly, those which are deprived of phlogiston, increase their capacity for specific fire. Thus, when regulus of antimony is deprived of its phlogiston, by calcination, it nearly trebles its specific fire. The same changes take place in crocus martis and in iron. This fact is generally true, whatever be

the nature of the substance; and even the æriiform ones are in the same case, for phlogisticated air has very little specific fire, common air has more of it, and dephlogisticated air shows a most prodigious quantity. From these facts it is clear, that phlogiston and fire are distinct, and incompatible substances; so that when one enters into the composition of any body, the other of course is expelled from it. Thus metals are calcined in consequence of a double attraction, by which the metal imparts its phlogiston to the air, while the air communicates its fire to the metallic calces, which is farther confirmed by the air found in metallic calces, whose increased weight by calcination corresponds to the air expelled from them, by their reduction to a metallic state. All combustible bodies are absolutely in the same case. Thus sulphur when burned contaminates the air, by the phlogiston it throws into it, and the produced vitriolic acid, if any, becomes impregnated with the same. In some cases the most intense heat or sensible fire is produced in the combustion; but in others it is very moderate. This variation generally depends on the quantity and quality of the vapors produced during the combustion; when these are very inconsiderable, and the residuum cannot absorb the fire emitted by the air, the remainder is precipitated or diffused all around, and produces a very sensible heat. On the contrary, if the vapors are capable of absorbing it, very little heat is produced. For instance, the vapor of waters absorbs about 300° of heat beyond that of its boiling state; from whence it follows, that, whenever there is a quantity of watery vapors produced by combustion, very little sensible fire must be felt. So when spirits of wine are fired, the heat then produced by the combustion is very inconsiderable, the greater part being absorbed by the watery vapors that are then produced; but, when the phosphorus of Kunkel is set on fire, the heat is very strong, there being but a small quantity of acid to carry off the specific fire that is set loose. This theory M. Magellan prefers to those of Messrs. Scheele, Fourcroy, and Lavoisier.

Combustible bodies, says M. Fourcroy, are those which have a strong attraction to unite with pure or dephlogisticated air; and combustion is nothing else but the act of that combination. This assertion is founded on the following facts: 1. That no substance can be burnt without air; 2. That the purer this air is the more rapid is the combustion; 3. That in combustion, an absorption or waste of air always takes place; and, 4. That the residuum contains often a very sensible quantity of that pure air which is absorbed, and which may sometimes be extracted from it.

According to this eminent chemist, dephlogisticated air is a compound of two substances, intimately combined; one is called by him the oxygenous principle, and the other specific elementary fire. During the combustion of sulphur, phosphorus, inflammable air, or any other substance of that kind, the oxygenous principle of the dephlogisticated air, combines with these bodies, to which it has a strong attraction, and forms new compounds of salts and other bodies; at the

same time that the elementary fire contained in these is set loose, and becomes sensible, producing heat and flame according to circumstances. Thus the fire produced in combustion does not proceed from the burned body, but from the decomposition of pure air, in which it is contained, in a latent and insensible state; while its oxygenous principle combines with the sulphur, phosphorus, or inflammable air, and forms vitriolic and phosphoric acids, or pure water.

As M. Scheele's theory, like that of Dr. Crawford, is founded on the ideal doctrine of phlogiston we shall give but a brief view of it. He considers heat and light themselves as compound substances. The former, according to him, consists of phlogiston and empyreal air. The calces of gold, reducible by heat alone, in a retort, show that phlogiston is contained in heat; because it combines with the calces to revive them, and the dephlogisticated air is found in the receiver. The precipitate per se of mercury, if revived in this manner, affords, he says, another instance of the truth of his doctrine: 'If phlogiston alone,' says he, 'could pass through the retort, there would not be found the empyreal air in the receiver, and the ignoble metals might be revived in the same manner.' Light, according to him, is a compound, containing phlogiston and heat, from which both may separate themselves in proper circumstances. A solution of silver in nitrous acid mixed with chalk, and exposed to the sun-shine, is revived into a metallic form by the phlogiston of light. Nitrous acid in a glass vessel, receives phlogiston from light, and becomes of an orange color; but if the glass be painted black, the acid receives the heat not the phlogiston. Even the various colored rays of light contain unequal shares of phlogiston; since the violet rays part more easily with their phlogiston to revive metals than any other. When light is not stopped in its passage, no heat is perceived; but if stopped in its course, the opposing body receives heat, and sometimes phlogiston. Light seems, therefore, to be the matter of heat, loaded with a superabundant quantity of phlogiston. That which comes out from a furnace produces heat on the surrounding bodies, which ascends with the rarefied air; proceeds forward in straight lines; and may be reflected from polished surfaces, with this peculiarity, that a concave glass mirror retains the heat, whilst it reflects the light; for although its focus is bright, yet it is not warm. A pane of glass also put before a burning mirror, retains the heat, and allows the light to pass through it. Fire is more or less heated to the luminous state of bodies, by which they are resolved into their constituent parts, and entirely destroyed. Combustion is the action of heat penetrating the pores of bodies, and destroying their cohesion; in this case the body parts with its phlogiston, provided there be a substance present which has a strong attraction for the inflammable principle. If the heating be performed in open air, the empyreal part, on account of its stronger attraction, unites with the inflammable principle, which is thus set at liberty; from which union the heat is compounded; and scarcely is this heat generated, when the combustible body is still more ex-

panded by it, and its phlogiston more laid open. The more the heat is increased, the more minute are the particles into which the combustible body is dissolved. The empyreal air meets more surfaces, comes in contact with more phlogiston, and forms an union with a greater quantity of it, which produces a radiant heat. At this moment the constituent parts of the combustible body are so much disunited by the still increasing heat, that the empyreal air, continuing to pour in upon it in streams, attracts the phlogiston in still greater quantities; and hence the most elastic substance, light, is composed; which, according to the quantity of combustible matter, shows various colors.

All this, however, is so exceedingly contrary to the common notions of mankind, that it can scarcely ever be seriously believed. The pure light of the sun can never be supposed by any mortal to consist principally of a substance as gross as the soot of our chimneys, without a degree of evidence of which the subject is quite incapable. With regard to the theory of Fourcroy, it is evidently deficient in one of the essential requisites to produce combustion, even fire itself; for if combustion depend only on the attraction between combustible bodies and pure air, then it ought to take place on all occasions wherever pure air and combustible bodies are presented to each other. But this is not the case; for though we put a piece of unlighted charcoal into a jar full of dephlogisticated air, no combustion will ensue. To produce this it is necessary that the charcoal be already, in part at least, in a state of combustion, or that fire be applied to it from without. This theory, therefore, instead of explaining the matter, gives not the smallest insight into it; since we are perpetually left to seek for the cause of the fire, which produced that in question; for the combination of a combustible body with air is the effect of combustion, not the cause. And Dr. Crawford's theory appears evidently insufficient from the following considerations: The degree of specific heat contained in bodies cannot be measured by any method yet known to us; that the phrase, quantity of heat, is vague, inaccurate, and improper; as expressing only the degree of sensible heat extricated, produced, generated, or which becomes perceptible in certain circumstances by us, without regard to the real quantity contained in the body itself, either originally, or after it has parted with that in question. Thus all experiments founded on the quantities of specific heat contained in different bodies, must be fallacious and inconclusive. Not to insist, however, on these general arguments, it is contrary to fact, that 'bodies which contain a large portion of phlogiston contain but a small share of specific heat,' and vice versa, as the Doctor asserts; which will appear from the following considerations: 1. The only methods by which we can measure the quantity of any material substance is either by its bulk or weight. 2. Whatever occupies space, and resists the touch, we have a right to call a material substance, whether we can see it, and weigh it, or not. Thus air, which is invisible, and not very easily ponderable, is universally allowed to be a sub-

stance and not a quality. 3. In cases where we cannot conveniently measure the weight of any substance, its quantity must always be judged of by its bulk. Thus the quantity of air contained in a bladder, or in a bellows, is always judged of by the degree of expansion of either. 4. Heat, which is still more subtle than air, is measured in this way, as Dr. Crawford himself acknowledges; for the expansions of mercury are, in an arithmetical progression, expressive of the real degrees of heat. 5. Applying this rule to bodies in general, we must conclude, that the expansions of all bodies will be in proportion to the degrees of heat which they contain. Thus, if a body is expanded by heat to double its bulk, and in this state remains even when the heating cause is withdrawn, we may then say with justice, that this body contains double the quantity of latent or specific heat that it did before, and so on. 6. As the vapor of water absorbs a vast quantity of heat, and likewise becomes prodigiously expanded in comparison with the water from whence it is produced, we may conclude that the quantity of heat absorbed, or of specific heat contained in the steam, is to the specific heat contained in the water as the bulk of the steam is to that of the water. It is difficult indeed to determine how much steam exceeds in bulk the water from which it is derived; but from some experiments, Dr. Black concludes that it is augmented in bulk between 1600 and 1700 times: and from the great quantity of heat emitted by steam during the process of condensation, which in some cases exceeds 1000° of Fahrenheit, we have reason to believe that the quantity of its expansions is proportionable to that of the heat absorbed. 7. As we have thus ascertained, by the great expansion of aqueous vapor, that it has absorbed a vast quantity of heat, it follows, that from the expansion of other substances we ought also to know the quantity of heat absorbed by them. In Dr. Priestley's experiments on the conversion of charcoal into inflammable air, he found that one grain of charcoal, dispersed by the heat of the sun in vacuo, gave six ounce measures of inflammable air. In another experiment, he found that 2½ grains of charcoal gave 15½ ounce measures of the same kind of air. But from a computation of the weight of the air so produced, it appears that at least an equal quantity of water with that of the charcoal goes to the composition of the aerial fluid. In measuring this expansion, therefore, we may allow one-half for that of the water requisite to form the inflammable air; and hence the grain of charcoal, properly speaking, absorbs only three ounce measures of fire. That this expansion was the effect of fire is evident: for there was nothing else present but fire, or the concentrated light of the sun; the experiment being performed by a burning-glass in vacuo. It cannot be a fact then, as Dr. Crawford asserts, that a phlogistic body contains but a small quantity of specific heat; for here so small a quantity as one grain of charcoal was made to contain as much specific fire as is equivalent in bulk to three ounce measures. The quantity of specific fire, therefore, contained in bodies, is not determined by their being combustible or not, or by their containing phlogiston or not. 8. The last

part of the doctor's theory must also be erroneous, viz. that 'In the act of combustion the dephlogisticated air communicates its fire to the combustible body.' For instead of this, when dephlogisticated and inflammable air, mixed together in due proportion, are set on fire, they shrink in a manner into nothing; so that instead of the one communicating its fire to the other, both of them throw out almost all the fire they contain; so that they are no longer air, but water. 9. Dr. Crawford's theory of combustion supersedes the necessity of any external cause to set on fire the combustible bodies. If dephlogisticated air attracts the phlogiston of the combustible body, and the phlogiston in the latter attracts the fire of the dephlogisticated air, the consequence of which is combustion: then, wherever dephlogisticated and inflammable air are mixed, combustion ought immediately to ensue. But this is not the case. A candle, a spark of electricity, or, in a word, some body already in a state of combustion, must be applied before we can produce the effect in question. We must therefore seek for the cause of combustion in the burning body applied, which will be found equally inexplicable: and thus we are not advanced one step in real knowledge, by Dr. Crawford's hypothesis.

The theory of Lavoisier was therefore, until a recent period, the only resort of chemists.

Dr. Robison, in his preface to Black's lectures, after tracing, with perhaps superfluous zeal, the expanded ideas of Lavoisier to the neglected germs of Hooke and Mayow, says, 'This doctrine concerning combustion, the great, the characteristic phenomenon of chemical nature, has at last received almost universal adoption, though not till after considerable hesitation and opposition; and it has made a complete revolution in chemical science.'

'The French theory of chemistry, as it was called,' says Dr. Ure, 'or hypothesis of combustion, as it should have been named, was for some time classed in certainty with the theory of gravitation. Alas! it is vanishing with the luminous phantoms of the day; but the sound logic, the pure candor, the numerical precision of inference, which characterise Lavoisier's Elements, will cause his name to be held in everlasting admiration.'

'It was the rival logic of Sir H. Davy,' continues this writer, 'aided by his unrivalled felicity of investigation, which first recalled chemistry from the pleasing labyrinth of fancy, to the more arduous but far more profitable and progressive career of reason. His researches on combustion and flame, already rich in blessings to mankind, would alone place him in the first rank of scientific genius.'

We copy, by permission, Dr. Ure's able digest of these researches:—'If Bacon were to revisit the earth,' it has been well said by another writer, 'this is exactly such a case as we should choose to place before him, in order to give him, in a small compass, an idea of the advancement which philosophy has made since the time when he had pointed out to her the route which she ought to pursue.'

'The phenomena of combustion may be con-

veniently considered under six heads;—1st. The temperature necessary to inflame different bodies. 2d. The nature of flame, and the relation between the light and heat which compose it. 3d. The heat disengaged by different combustibles in burning. 4th. The causes which modify and extinguish combustion, and of the safe-lamp. 5th. Invisible combustion. 6th. Practical inferences.

1st. Of the temperature necessary to inflame different bodies. 1st. A simple experiment shows the successive combustibilities of the different bodies. Into a long bottle with a narrow neck, introduce a lighted taper, and let it burn till it is extinguished. Carefully stop the bottle, and introduce another lighted taper. It will be extinguished before it reaches the bottom of the neck. Then introduce a small tube, containing zinc, and dilute sulphuric acid, at the aperture of which the hydrogen is inflamed. The hydrogen will be found to burn in whatever part of the bottle the tube is placed. After the hydrogen is extinguished, introduce lighted sulphur. This will burn for some time; and after its extinction phosphorus will be as luminous as in the air, and, if heated in the bottle, will produce a pale yellow flame of considerable density. Phosphorus is said to take fire when heated to 150° , and sulphur to 550° . Hydrogen inflames with chlorine at a lower temperature than with oxygen. By exposing oxygen and hydrogen, confined in glass tubes, to a very dull red (about 800° F.) they explode. When the heat was about 700° F. they combined rapidly with a species of silent combustion. A mixture of common air and hydrogen was introduced into a small copper tube, having a stopper not quite tight; the copper tube was placed in a charcoal fire; before it became visibly red-hot, an explosion took place, and the stopper was driven out. We see, therefore, that the inflaming temperature is independent of compression or rarefaction.

The ratio of the combustibility of the different gaseous matters is likewise, to a certain extent, as the masses of heated matters required to inflame them. Thus, an iron-wire $\frac{1}{40}$ th of an inch, heated cherry-red, will not inflame olefiant gas, but it will inflame hydrogen gas. A wire of $\frac{1}{8}$ th, heated to the same degree, will inflame olefiant gas. But a wire $\frac{1}{50}$ th of an inch must be heated to whiteness, to inflame hydrogen, though at a low red heat it will inflame biphosphureted gas. Yet wire of $\frac{1}{40}$ th, heated even to whiteness, will not inflame mixtures of fire-damp. Carbonic oxide inflames in the atmosphere when brought into contact with an iron wire heated to dull redness; whereas carbureted hydrogen is not inflammable, unless the iron is heated to whiteness, so as to burn with sparks. These circumstances will explain why a mesh of wire, so much finer or smaller, is required to prevent the explosion from hydrogen and oxygen from passing; and why so coarse a texture and wire are sufficient to prevent the explosion of the fire-damp, fortunately the least combustible of all the inflammable gases known. The flame of sulphur, which kindles at so low a temperature, will exist under refrigerating processes, which extinguish the flame of hydrogen and all carbureted gases. Let the smallest possible flame be made by a

single thread of cotton immersed in oil, and burning immediately upon the surface of the oil. It will be found to yield a flame about $\frac{1}{30}$ th of an inch in diameter. Let a fine iron wire of $\frac{1}{50}$ th of an inch, made into a ring of $\frac{1}{10}$ th of an inch diameter, be brought over the flame. Though at such a distance, it will instantly extinguish the flame, if it be cold; but if it be held above the flame, so as to be slightly heated, the flame may be passed through it without being extinguished. That the effect depends entirely on the power of the metal to abstract the heat of flame, is shown by bringing a glass capillary ring of the same diameter and size over the flame. This being a much worse conductor of heat, will not, even when cold, extinguish it. If its size, however, be made greater, and its circumference smaller, it will act like the metallic wire, and require to be heated to prevent it from extinguishing the flame. Now, a flame of sulphur may be made much smaller than that of hydrogen; one of hydrogen may be made much smaller than that of a wick fed with oil; and that of a wick fed with oil smaller than that of carbureted hydrogen. A ring of cool wire, which instantly extinguishes the flame of carbureted hydrogen, diminishes but slightly the size of a flame of sulphur of the same dimensions. By the following simple contrivance, we may determine the relative facility of burning, among different combustibles. Prepare a series of metallic globules of different sizes, by fusion at the end of iron wires, and light a series of very minute flames of different bodies all of one size. If a globule $\frac{1}{20}$ th of an inch diameter be brought near an oil flame of $\frac{1}{30}$ th in diameter, it will extinguish it, when cold, at the distance of a diameter. The size of the spherule adequate to the extinction of the particular flame, will be a measure of its combustibility. If the globule be heated, however, the distance will diminish at which it produces extinction. At a white heat, the globule, in the above instance, does not extinguish it by actual contact, though at a dull red heat it immediately produces the effect.

2d. Of the nature of flame, and of the relation between the light and the heat which compose it. The flame of combustible bodies may, in all cases, be considered as the combustion of an explosive mixture of inflammable gas, or vapor, with air. It cannot be regarded as a mere combustion, at the surface of contact, of the inflammable matter. This fact is proved by holding a taper, or a piece of burning phosphorus, within a large flame made by the combustion of alcohol. The flame of the taper, or of the phosphorus, will appear in the centre of the other flame, proving that there is oxygen even in its interior part. When a wire-gauche safe-lamp is made to burn, in a very explosive mixture of coal gas and air, the light is feeble, and of a pale color. Whereas the flame of a current of coal gas burnt in the atmosphere, as is well known by the phenomena of the gas-lights, is extremely brilliant. It becomes, therefore, a problem of some interest, "Why the combustion of explosive mixtures, under different circumstances, should produce such different appearances?" In reflecting on the circumstances of these two species of combustion,

Sir H. Davy was led to imagine that the cause of the superiority of the light of the stream of coal-gas, might be owing to the decomposition of a part of the gas, towards the interior of the flame, where the air was in the smallest quantity, and the deposition of solid charcoal, which first by its ignition, and afterwards by its combustion, increased in a high degree the intensity of the light. The following experiments show that this is the true solution of the problem:—

‘If we hold a piece of wire-gause of about 900 apertures to the square inch, over a stream of coal-gas issuing from a small pipe, and if we inflame the gas above the wire-gause, left almost in contact with the orifice of the pipe, it burns with its usual bright light. On raising the wire-gause so as to cause the gas to be mixed with more air before it inflames, the light becomes feebler, and at a certain distance the flame assumes the precise character of that of an explosive mixture burning within the lamp. But though the light is so feeble in this case, the heat is greater than when the light is much more vivid. A piece of wire of platina, held in this feeble blue flame, becomes instantly white-hot. On reversing the experiment, by inflaming a stream of coal gas, and passing a piece of wire-gause gradually from the summit of the flame to the orifice of the pipe, the result is still more instructive. It is found that the apex of the flame, intercepted by the wire-gause, affords no solid charcoal; but, in passing it downwards, solid charcoal is given off in considerable quantities, and prevented from burning by the cooling agency of the wire-gause. At the bottom of the flame, where the gas burned blue, in its immediate contact with the atmosphere, charcoal ceased to be deposited in visible quantities.

‘The principle of the increase of the brilliancy and density of flame, by the production and ignition of solid matter, appears to admit of many applications. Thus, olefiant gas gives the most brilliant white light of all combustible gases, because, as we learn from Berthollet’s experiments, related under carbureted hydrogen, at a very high temperature it deposits a very large quantity of solid carbon. Phosphorus, which rises in vapor at common temperatures, and the vapor of which combines with oxygen at those temperatures, is always luminous; for each particle of acid formed, must, there is every reason to believe, be white-hot. So few of these particles, however, exist in a given space, that they scarcely raise the temperature of a solid body exposed to them, though, as in the rapid combustion of phosphorus, where immense numbers are existing in a small space, they produce a most intense heat. The above principle readily explains the appearances of the different parts of the flame of burning bodies, and of flame urged by the blow-pipe. The point of the inner blue flame, where the heat is greatest, is the point where the whole of the charcoal is burned in its gaseous combinations, without previous deposition.

‘It explains also the intensity of the light of those flames in which fixed solid matter is produced in combustion, such as the flame of phosphorus and of zinc in oxygen, &c. and of

potassium in chlorine, and the feebleness of the light of those flames in which gaseous and volatile matter alone is produced, such as those of hydrogen and of sulphur in oxygen, phosphorus in chlorine, &c. It offers means of increasing the light of certain burning substances, by placing in their flames even incombustible substances. Thus the intensity of the light of burning sulphur, hydrogen, carbonic oxide, &c. is wonderfully increased by throwing into them oxide of zinc, or by placing in them very fine amianthus or metallic gause. It leads to deductions concerning the chemical nature of bodies, and various phenomena of their decomposition. Thus ether burns with a flame, which seems to indicate the presence of olefiant gas in that substance. Alcohol burns with a flame similar to that of a mixture of carbonic oxide and hydrogen. Hence the first is probably a binary compound of olefiant gas and water, and the second of carbonic oxide and hydrogen. When protochloride of copper is introduced into the flame of a candle or lamp, it affords a peculiar dense and brilliant red light, tinged with green and blue towards the edges, which seems to depend upon the chlorine being separated from the copper by the hydrogen, and the ignition and combustion of the solid copper and charcoal.

‘Similar explanations may be given of the phenomena presented by the action of other combinations of chlorine on flame; and it is probable, in many of those cases, when the color of flame is changed by the introduction of incombustible compounds, that the effect depends on the production, and subsequent ignition or combustion, of inflammable matter from them. Thus the rose-colored light given to flame by the compounds of strontium and calcium, and the yellow color given by those of barium, and the green by those of boron, may depend upon a temporary production of these bases, by the inflammable matter of the flame. Dr. Clarke’s experiments on the reduction of barytes, by the hydroxygen lamp, is favorable to this idea. Nor should any supposed inadequacy of heat in ordinary flame prevent us from adopting this conclusion. Flame, or gaseous matter, heated so highly as to be luminous, possesses a temperature beyond the white heat of solid bodies, as is shown by the circumstance, that air not luminous will communicate this degree of heat. This is proved by a simple experiment. Hold a fine wire of platinum about 1-20th of an inch from the exterior of the middle of the flame of a spirit-lamp, and conceal the flame by an opaque body. The wire will become white-hot in a space where there is no visible light. The real temperature of visible flame is perhaps as high as any we are acquainted with. Mr. Tennant used to illustrate this position by fusing a small filament of platinum in the flame of a common candle. These views will probably offer illustrations of electrical light. The voltaic arc of flame from the great battery differs in color and intensity, according to the substances employed in the circuit, and is infinitely more brilliant and dense with charcoal than with any other substance. May not this depend, says Sir H. Davy, upon particles of the substances separated by

the electrical attractions? And the particles of charcoal being the lightest among solid bodies, as their prime equivalent shows, and the least coherent, would be separated in the largest quantities. The heat of flames may be actually diminished by increasing their light, at least the heat communicable to other matter, and vice versâ. The flame from combustion, which produces the most intense heat amongst those which have been examined, is that of a mixture of oxygen and hydrogen compressed in Newmann's blow-pipe apparatus. This flame is hardly visible in bright day-light; yet it instantly fuses the most refractory bodies; and the light from solid bodies ignited in it is so vivid as to be painful to the eye. This application certainly originated from Sir H. Davy's discovery, that the explosion from oxygen and hydrogen would

not communicate through very small apertures, and he himself first tried the experiment with a fine glass capillary tube. The flame was not visible at the end of this tube, being overpowered by the brilliant star of the glass, ignited at the aperture.

3. 'Of the heat disengaged by different combustibles in the act of burning.—Lavoisier, Crawford, Dalton, and Rumford, in succession, made experiments to determine the quantity of heat evolved in the combustion of various bodies. The apparatus used by the last was perfectly simple, and perhaps the most precise of the whole. The heat was conducted by flattened pipes of metal into the heart of a body of water, and was measured by the temperature imparted. The following is a general table of results:—

Substances burned, 1 lb.	Oxygen consumed in lbs.	Ice melted in lbs.			
		Lavoisier.	Crawford.	Dalton.	Rumford.
Hydrogen	7.5	295.6	480	320	
Carbureted hydrogen	4			85	
Olefiant gas	3.50			88	
Carbonic oxide	0.58			25	
Olive oil	3.00	149	89	104	94.07
Rape oil	3.0				124.10
Wax	3.0	133	97	104	126.24
Tallow	3.0	96		104	111.58
Oil of turpentine				60	
Alcohol	2.0 ?			58	67.47
Ether, sulphuric	3			62	107.03
Naphtha					97.83
Phosphorus	1.3	100		60	
Charcoal	2.66	96.5	69	40	
Sulphur	1.00			20	
Camphor				70	
Caoutchouc				42	

'The discrepancies in the preceding table are sufficient to show the necessity of new experiments on the subject. Count Rumford made a series of experiments on the heat given out during the combustion of different woods. He found that one pound of wood by burning, produced as much heat as would have melted from about thirty-four to fifty-four pounds of ice. The average quantity is about forty. MM. Clement and Desormes find that woods give out heat in the ratio of their respective quantities of carbon; which they state to be equal to one-half of their total weight. Hence they assign forty-eight pounds as the quantity of ice melted, in burning one of wood. In treating of acetic acid and carbon, I have already taken occasion to state, that they appear probably to overrate the proportion of carbon in woods.

'The preceding table is incorrectly given in several respects by our systematic writers; Dr. Thomson, for example, states, that one pound of hydrogen consumes only six pounds of oxygen, though the saturating proportion assigned by him is eight pounds. The proportions of oxygen consumed by olive oil, phosphorus, charcoal, and sulphur, are all in like manner erroneous. In vol. i. p. 184, of Dr. Black's Lectures, we

have the following notes: 'One hundred pounds weight of the best Newcastle coal, when applied by the most judiciously constructed furnace, will convert about 1½ wine hogsheads of water into steam, that supports the pressure of the atmosphere.' 1½ hogsheads of water weigh about 790 pounds. Hence one part of coal will convert nearly eight parts of water into steam. Count Rumford says, that the heat generated in the combustion of one pound of pit-coal, would make 36½ pounds of ice-cold water boil. But we know that it requires fully 5½ times as much heat to convert the boiling water into steam.

Therefore, $\frac{36.3}{5.5} = 6\frac{3}{5}$, is the weight of water that would be converted into steam by one pound of coal. Mr. Watt found that it requires eight feet surface of boiler to be exposed to fire to boil off one cubic foot of water per hour, and that a bushel, or eighty-four pounds of Newcastle coal, so applied, will boil off from eight to twelve cubic feet. He rated the heat, expended in boiling off a cubic foot of water, to be about six times as much as would bring it to a boiling heat from the medium temperature, 55°, in this climate. The mean quantity is ten cubic feet, which weigh 625 pounds. Hence one pound of coal

burnt is equivalent to boil off in steam nearly $7\frac{1}{2}$ pounds of water, at the temperature of 55° . In situations where wood was employed for fuel to Mr. Watt's engines, he allowed three times the weight of it, that he did of Newcastle coal. The cubical coal of the Glasgow coal district, is reckoned to have only three-fourths the calorific power of the Newcastle coal; and the small coal or culin requires to be used in double weight, to produce an equal heat with the larger pieces. A bushel of Newcastle coal is equivalent to a hundred weight of the Glasgow.

I shall now describe the experiments recently made on this subject by Sir. H. Davy, subscriber to his researches on the nature of flame. A mercurial gas-holder, furnished with a system of stop-cocks, terminated in a strong tube of platinum, having a minute aperture. Above this was fixed a copper cup filled with olive oil, in which a thermometer was placed. The oil was heated to 212° , to prevent any difference in the communication of heat, by the condensation of aqueous vapor: the pressure was the same for the different gases; and they were consumed as nearly as possible in the same time, and the flame applied to the same point of the copper cup, the bottom of which was wiped after each experiment. The results were as follows:—

Substances.	Rise of ther from 212° to	Oxygen consumed.	Ratios of heat.
Olefiant gas,	270°	6·0	9·66
Hydrogen,	238	1·0	26·0
Sulph. hydrogen,	232	3·0	6·66
Coal gas,	236	4·0	6·00
Carbonic oxide,	218	1·0	6·00

The data on which Sir. H. calculates the ratios of heat, are the elevations of temperature and the quantities of oxygen consumed conjointly. We see that hydrogen produces more heat in combustion than any of its compounds, a fact accordant with Mr. Dalton's results in the former table; only Sir H. Davy's ratio is more than double that of Mr. Dalton's, as to hydrogen, and carbureted hydrogen. On this point, however, Sir H. with his usual sagacity remarks, that it will be useless to reason upon the ratios as exact, for charcoal was deposited from both the olefiant gas and coal gas during the experiment, and much sulphur was deposited from the sulphureted hydrogen. It confirms, however, the general conclusions, and proves that hydrogen stands at the head of the scale, and carbonic oxide at the bottom. It might at first view be imagined, that, according to this scale, the flame of carbonic oxide ought to be extinguished by rarefaction at the same degree as that of carbureted hydrogen; but it must be remembered, as has been already shown, that carbonic oxide is a much more easily kindled, a more ascensible gas.

4. Of the causes which modify or extinguish combustion or flame. The earlier experimenters upon the Boylean vacuum observed, that flame

ceased in highly rarefied air; but the degree of rarefaction necessary for this effect has been differently stated. On this point, Sir H. Davy's investigations are peculiarly beautiful and instructive. When hydrogen gas, slowly produced from a proper mixture, was inflamed at a fine orifice of a glass tube, as in Priestley's philosophical candle, so as to make a jet of flame of about 1-6th of an inch in height, and introduced under the receiver of an air-pump, containing from 200 to 300 cubical inches of air, the flame enlarged as the receiver became exhausted; and when the gauge indicated a pressure between four and five times less than that of the atmosphere, was at its maximum of size; it then gradually diminished below, but burned above, till its pressure was between seven and eight times less; when it became extinguished.

To ascertain whether the effect depended upon the deficiency of oxygen, he used a larger jet with the same apparatus, when the flame, to his surprise, burned longer; even when the atmosphere was rarefied ten times; and this in repeated trials. When the larger jet was used, the point of the glass tube became white-hot, and continued red-hot till the flame was extinguished. It immediately occurred to him, that the heat communicated to the gas by this tube, was the cause that the combustion continued longer in the last trials when the larger flame was used; and the following experiments confirmed the conclusion. A piece of wire of platinum was coiled round the top of the tube, so as to reach into and above the flame. The jet of gas of 1-6th of an inch in height was lighted, and the exhaustion made. The wire of platinum soon became white-hot in the centre of the flame, and a small point of wire near the top fused. It continued white-hot till the pressure was six times less. When it was ten times it continued red-hot at the upper part, and, as long as it was dull red, the gas, though certainly extinguished below, continued to burn in contact with the hot wire; and the combustion did not cease until the pressure was reduced thirteen times. It appears from this result, that the flame of hydrogen is extinguished in rarefied atmospheres, only when the heat it produces is insufficient to keep up the combustion; which appears to be when it is incapable of communicating visible ignition to metal; and as this is the temperature required for the inflammation of hydrogen (see section 1), at common pressure, it appears that its combustibility is neither diminished nor increased by rarefaction from the removal of pressure.

According to this view, with respect to hydrogen, it should follow, that those amongst other combustible bodies which require less heat for their ascension, ought to burn in more rarefied air than those that require more heat; and those which produce much heat in their combustion ought to burn, other circumstances being the same, in more rarefied air than those that produce little heat. Every experiment since made confirms these conclusions. Thus olefiant gas, which approaches nearly to hydrogen, in the temperature produced by its combustion, and which does not require a much higher temperature for its ascension, when its flame was made

by a jet of gas from a bladder connected with a small tube, furnished with a wire of platinum, under the same circumstances as hydrogen, ceased to burn when the pressure was diminished between ten and eleven times. And the flames of alcohol and of the wax taper, which require a greater consumption of caloric for the volatilisation and decomposition of their combustible matter, were extinguished when the pressure was five or six times less without the wire of platinum, and seven or eight times less when the wire was kept in the flame. Light carbureted hydrogen, which produces, as we have seen, less heat in combustion than any of the common combustible gases, except carbonic oxide, and which requires a higher temperature for its ascension than any other, has its flame extinguished, even though the tube was furnished with the wire when the pressure was below 1-4th. The flame of carbonic oxide, which, though it produces little heat in combustion, is as ascensible as hydrogen, burned when the wire was used, the pressure being 1-6th. The flame of sulphureted hydrogen, the heat of which is in some measure carried off by the sulphur produced by its decomposition during its combustion in rare air, when burned in the same apparatus as the olefiant and other gases, was extinguished when the pressure was 1-7th. Sulphur, which requires a lower temperature for its ascension than any common inflammable substance, except phosphorus, burned with a very feeble blue flame in air rarefied fifteen times; and at this pressure the flame heated a wire of platinum to dull redness; nor was it extinguished till the pressure was reduced to 1-20th. From the preceding experimental facts we may infer, that the taper would be extinguished at a height of between nine and ten miles, hydrogen between twelve and thirteen, and sulphur between fifteen and sixteen. Phosphorus, as has been shown by M. Van Marum, burns in an atmosphere rarefied sixty times. Sir H. Davy found, that phosphureted hydrogen produced a flash of light when admitted into the best vacuum that could be made by an excellent pump of Nairne's construction. Chlorine and hydrogen inflame at a much lower temperature than oxygen and hydrogen. Hence the former mixture explodes when rarefied twenty-four times; the latter ceases to explode when rarefied eighteen times. Heat extrinsically applied, carries on combustion, when it would otherwise be extinguished. Camphor in a thick metallic tube, which disperses the heat, ceases to burn in air rarefied six times; in a glass tube which becomes ignited, the flame of camphor exists under a ninefold rarefaction. Contact with a red-hot iron makes naphtha glow with a lambent flame at a rarefaction of thirty times; though, without foreign heat, its flame dies at an atmospheric rarefaction of six. If the mixture of oxygen and hydrogen, expanded to its non-explosive tenuity, be exposed to the ignition of a glass tube, the electric spark will then cause an explosion, at least in the heated portion of the gases.

‘We shall now detail briefly the effects of rarefaction by heat on combustion and explosion. We know that air, by being heated from 32° to

212° expands 3-8ths, or eight parts become eleven. Sir H. Davy justly estimates the temperature corresponding to an increase of one volume of air at 212°, into two volumes and a half, (which took place when the enclosing glass tube began to soften with ignition), at 1035° Fahrenheit. Sir H. introduced into a small glass tube, over well boiled mercury, a mixture of two parts of hydrogen and one of oxygen, and heated the tube by a spirit-lamp, till the volume of the gas was increased from 1 to 2·5. By means of a blow-pipe and another lamp, he made the upper part of the tube red-hot, when an explosion instantly took place. This experiment refutes the notions of M. de Grotthus, on the non-explosiveness of that mixture, when expanded by heat. He introduced into a bladder a mixture of oxygen and hydrogen, and connected this bladder with a thick glass tube of about 1-6th of an inch in diameter, and three feet long, curved so that it could be gradually heated in a charcoal furnace: two spirit-lamps were placed under the tube, where it entered the charcoal fire, and the mixture was very slowly passed through. An explosion took place before the tube was red-hot. This fine experiment shows, that expansion by heat, instead of diminishing the accendibility of gases, enables them, on the contrary, to explode apparently at a lower temperature; which seems perfectly reasonable, as a part of the heat communicated by any ignited body, must be lost in gradually raising the temperature. M. de Grotthus has stated, that if a glowing coal be brought into contact with a mixture of oxygen and hydrogen, it only rarefies them, but does not explode them. This depends on the degree of heat communicated by the coal. If it is red in day-light, and free from ashes, it uniformly explodes the mixture. If its redness be barely visible in the shade, it will not explode them, but cause their slow combination. The general phenomenon is wholly unconnected with rarefaction, as is shown by the following circumstance: when the heat is greatest, and before the invisible combination is completed, if an iron wire, heated to whiteness, be placed upon the coal within the vessel, the mixture instantly explodes.

‘Subcarbureted hydrogen, or fire-damp, as has been shown, requires a very strong heat for its inflammation. It therefore offered a good substance for an experiment on the effect of high degrees of rarefaction, by heat, on combustion. One part of this gas, and eight of air, were mixed together, and introduced into a bladder furnished with a capillary tube. This tube was heated till it began to melt. The mixture was then passed through it into the flame of a spirit-lamp, when it took fire, and burned with its own peculiar explosive light, beyond the flame of the lamp; and when withdrawn, though the aperture was quite white-hot, it continued to burn vividly. That the compression in one part of an explosive mixture, produced by the sudden expansion of another part by heat, or the electric spark, is not the cause of combustion, as has been supposed by Mr. Higgins, M. Bertholiet, and others, appears to be evident from what has been stated, and is rendered still more so by the following facts:—A mixture of biphosphureted hydrogen

gas and oxygen, which explode at a heat a little above that of boiling water, was confined by mercury, and very gradually heated on a sand bath. When the temperature of the mercury was 242° , the mixture exploded. A similar mixture was placed in a receiver communicating with a condensing syringe, and condensed over mercury till it occupied only one-fifth of its original volume. No explosion took place, and no chemical change had occurred; for, when its volume was restored, it was instantly exploded by the spirit-lamp. It would appear then that *the heat* given out by the compression of gases, is the real cause of the combustion which it produces; and that at certain elevations of temperature, whether in rarefied or compressed atmospheres, explosion or combustion occurs; that is, bodies combine with the production of heat and light. Since it appears that gaseous matter acquires a double, triple, quadruple, &c., bulk, by the successive increments of 480° Fahrenheit, $2 \times 480^{\circ}$, $3 \times 480^{\circ}$, &c., we may gain approximations to the temperature of flame, by measuring the expansion of a gaseous mixture at the instant of explosion, provided the resulting compound gas occupy, after cooling, the same bulk as the sum of its constituents. Now this is the case with chlorine and hydrogen, and with prussine and oxygen. The latter detonated in the proportion of one to two, in a tube of about two-fifths of an inch diameter, displaced a quantity of water, which demonstrated an expansion of fifteen times their original bulk. Hence $15 \times 480^{\circ} = 7200^{\circ}$ of Fahrenheit; and the real temperature is probably

much higher, for heat must be lost by communication to the tube and the water. The heat of the gaseous carbon in combustion in this gas, appears more intense than that of hydrogen; for it was found that a filament of platinum was fused by a flame of prussine (cyanogen) in the air, which was not fused by a similar flame of hydrogen. We have thus detailed the modifications produced in combustion by rarefaction, mechanical and calorific. It remains on this head to state the effects of the mixture of different gases, and those of different cooling orifices, on flame.

‘In Sir H. Davy’s first paper on the fire-damp of coal mines, he mentioned that carbonic acid had a greater influence in destroying the explosive power of mixtures of fire-damp and air, than azote; and he supposed the cause to be its greater density and capacity for heat, in consequence of which it might exert a greater cooling agency, and thus prevent the temperature of the mixture from being raised to that degree necessary for combustion. He subsequently made a series of experiments with the view of determining how far this idea is correct, and for the purpose of ascertaining the general phenomena of the effects of the mixture of gaseous substances upon explosion and combustion. He took given volumes of a mixture of two parts of hydrogen and one part of oxygen by measure, and, diluting them with various quantities of different elastic fluids, he ascertained at what degree of dilution the power of inflammation by a strong spark from a Leyden phial was destroyed. He found that for one of the mixture, inflammation was

	Prevented by.	Permitted with.	Cooling power, air, = 1.
Of hydrogen	8	6	2.66
Oxygen	9	7	1.12
Nitrous oxide	11	10	0.75 (the mean)
Subcarbureted hydrogen	1	$\frac{2}{3}$	2.18 (coal gas)
Sulphureted hydrogen	2	$1\frac{1}{2}$	
Olefiant gas	$\frac{1}{2}$	$\frac{1}{3}$	1.6
Muriatic acid gas	2	$1\frac{1}{2}$	
Chlorine			0.66
Silicated fluoric gas	$1\frac{1}{2}$	$\frac{1}{2}$	
Azote			1.33
Carbonic acid			0.727

The first column of the preceding table shows that other causes, besides density and capacity for heat, interfere with the phenomena. Thus nitrous oxide, which is nearly one-third denser than oxygen, and which, according to Delaroché and Berard, has a greater capacity for heat, in the ratio of 1.3503 to 0.9765 by volume, has lower powers of preventing explosion. Hydrogen also, which is fifteen times lighter than oxygen, and which in equal volumes has a smaller capacity for heat, certainly has a higher power of preventing explosion; and olefiant gas exceeds all other gaseous substances, in a much higher ratio than could have been expected from its density and capacity.

‘I have deduced the third column from Sir H. Davy’s experiments on the relative times in which a thermometer, heated to 160° , when

plunged into a volume of twenty-one cubic inches of the respective gases at 52° , took to cool down to 106° . Where an elastic fluid exerts a cooling influence on a solid surface, the effect must depend principally upon the rapidity with which its particles change their places; but where the cooling particles are mixed throughout a mass with other gaseous particles, their effect must depend principally upon the power they possess of rapidly abstracting heat from the contiguous particles; and this will depend probably upon two causes, the simple abstracting power by which they become quickly heated, and their capacity for heat, which is great in proportion as their temperatures are less raised by this abstraction. The power of elastic fluids to abstract heat from solids, appears from the above experiments to be in some inverse ratio to their density; and there

seems to be something in the constitution of the light gases, which enables them to carry off heat from solid surfaces in a different manner from that in which they would abstract it in gaseous mixtures, depending probably on the mobility of their parts. Those particles which are lightest must be conceived most capable of changing place, and would therefore cool solid surfaces most rapidly: in the cooling of gaseous mixtures the mobility of the particles can be of little consequence.

Whatever be the cause of the different cooling powers of the different elastic fluids in preventing inflammation, very simple experiments show that they operate uniformly with respect to the different species of combustion; and that those explosive mixtures, or inflammable bodies, which require least heat for their combustion, require larger quantities of the different gases to prevent the effect, and vice versa. Thus one of chlorine, and one of hydrogen, still inflame when mixed with eighteen times their bulk of oxygen; whereas a mixture of carbureted hydrogen and oxygen, in the proper proportions (one and two) for combination, have their inflammation prevented by less than three times their volume of oxygen. A wax taper was instantly extinguished in air mixed with one-tenth of silicated fluoric acid, and in air mixed with one-sixth of muriatic acid gas; but the flame of hydrogen burned readily in those mixtures; and in mixtures which extinguished the flame of hydrogen, the flame of sulphur burned. In cases, however, in which the heat required for chemical union is very small, as in the instance of hydrogen and chlorine, a mixture which prevents inflammation will not prevent combination; that is, the gases will combine without any flash. If two volumes of carbureted hydrogen be added to a mixture of one of chlorine with one of hydrogen, muriatic acid is formed throughout the mixture, and heat produced, as was evident from the expansion when the spark passed, and the rapid contraction afterwards; but the heat was so rapidly carried off by the quantity of carbureted hydrogen, that no flash was visible.

Experiments on combustion in condensed air, to see if the cooling power was much increased thereby, show that, as rarefaction does not diminish considerably the heat of flame in atmospheric air, so neither does condensation considerably increase it; a circumstance of great importance in the constitution of our atmosphere, which at all heights or depths, at which man can exist, still preserves the same relations to combustion. It may be concluded from the general law, that, at high temperatures, gases not concerned in combustion will have less power of preventing that operation, and likewise that steam and vapors, which require a considerable heat for their formation, will have less effect in preventing combustion, particularly of those bodies requiring low temperatures, than gases at the usual heat of the atmosphere. Thus a very large quantity of steam is required to prevent sulphur from burning. A mixture of oxygen and hydrogen will explode by the electric spark, though diluted with five times its volume of steam; and even a mixture of air and carbureted hydrogen gas, the

least explosive of all mixtures, requires a third of steam to prevent its explosion, whereas one-fifth of azote will produce that effect. These trials were made over mercury. Heat was applied to water over the mercury, and 37.5 for 100 parts = $\frac{3}{8}$, was regarded as the correction for the expansion of the gases.

We shall now treat of the effects of cooling orifices on flame. The knowledge of the cooling power of elastic media, in preventing the explosion of the fire-damp, led the illustrious English chemist to those practical researches which terminated in his grand discovery of the wire-gause safe-lamp. The general investigation of the relation and extent of those powers, serves to elucidate the operation of wire-gause, and other tissues or systems of apertures permeable to light and air, in intercepting flame, and confirms the views originally given of this marvellous phenomenon. We have seen that flame is gaseous matter, heated so highly as to be luminous, and that to a degree of temperature beyond the white heat of solid bodies; for air not luminous will communicate this degree of heat. When an attempt is made to pass flame through a very fine mesh of wire-gause of the common temperature, the gause cools each portion of the elastic matter that passes through it, so as to reduce its temperature below that degree at which it is luminous. This diminution of temperature is proportional to the smallness of the mesh, and to the mass of the metal. The power of a metallic or other tissue to prevent explosion, will depend upon the heat required to produce the combustion, as compared with that acquired by the tissue. Hence, the flame of the most inflammable substances, and of those that produce most heat in combustion, will pass through a metallic tissue, that will interrupt the flame of less inflammable substances, or those that produce little heat in combustion. Or, the tissue being the same, and impermeable to all flames at common temperatures, the flames of the most combustible substances, and of those which produce most heat, will most readily pass through it when it is heated, and each will pass through it at a different degree of temperature. In short, all the circumstances which apply to the effect of cooling mixtures upon flame, will apply to cooling perforated surfaces. Thus, the flame of phosphureted hydrogen, at common temperatures, will pass through a tissue sufficiently large, not to be immediately choked up by the phosphoric acid formed, and the phosphorus deposited. If a tissue, containing above 700 apertures to the square inch, be held over the flame of phosphorus or phosphureted hydrogen, it does not transmit the flame till it is sufficiently heated to enable the phosphorus to pass through it in vapor. Phosphureted hydrogen is decomposed by flame, and acts exactly like phosphorus. In like manner, a tissue of 100 apertures to the square inch, made of a wire of one-sixtieth, will at common temperatures, intercept the flame of a spirit-lamp, but not that of hydrogen. But when strongly heated, it no longer arrests the flame of alcohol. A tissue which will not interrupt the flame of hydrogen when red-hot, will still intercept that of olefant gas; and a heated tissue, which would

communicate explosion from a mixture of olefiant gas and air, will stop an explosion from a mixture of fire-damp, or carburated hydrogen. The latter gas requires a considerable mass of heated metal to inflame it, or contact with an extensive heated surface. An iron-wire of one-twentieth of an inch, and eight inches long, red-hot, when held perpendicularly in a stream of coal gas, did not inflame it; nor did a short wire of one-sixth of an inch produce the effect, when held horizontally. But wire of the latter size, when six inches of it were red-hot, and when it was held perpendicularly in a bottle containing an explosive mixture, so that heat was communicated successively to portions of the gas, produced its explosion.

‘The scale of gaseous accension, given in the first section, explains why so fine a mesh of wire is required to hinder the explosion from hydrogen and oxygen to pass; and why so coarse a texture and wire control the explosion of fire-damp. The general doctrine, indeed, of the operation of wire-gause, cannot be better elucidated, than in its effects upon the flame of sulphur. When wire-gause of 600 or 700 apertures to the square inch, is held over the flame, fumes of condensed sulphur immediately come through it, and the flame is intercepted. The fumes continue for some instants, but on the increase of the heat they diminish; and at the moment when they disappear, which is long before the gause becomes red-hot, the flame passes; the temperature at which sulphur burns being that at which it is gaseous. Where rapid currents of explosive mixtures, however, are made to act upon wire-gause, it is of course much more rapidly heated; and therefore, the same mesh which arrests the flames of explosive mixtures at rest, will suffer them to pass when in rapid motion. But, by increasing the cooling surface, by diminishing the apertures in size, or increasing their depth, all flames, however rapid their motion, may be arrested. Precisely the same law applies to explosions acting in close vessels. Very minute apertures, when they are only few in number, will permit explosions to pass, which are arrested by much larger apertures when they fill a whole surface. A small aperture was drilled at the bottom of a wire-gause lamp, in the cylindrical ring, which confines the gause. This, though less than one-eighteenth of an inch in diameter, transmitted the flame, and fired the external atmosphere, in consequence of the whole force of the explosion of the thin stratum of the mixture included within the cylinder, driving the flame through the aperture. Had the whole ring, however, been composed of such apertures separated by wires, it would have been perfectly safe.

‘Nothing can demonstrate more decidedly, than these simple facts and observations, that the interruption of flame, by solid tissues, permeable to light and air, depends upon no recondite or mysterious cause, but on their cooling powers, simply considered as such. When a light, included in a cage of wire-gause, is introduced into an explosive atmosphere of fire-damp at rest, the maximum of heat is soon obtained: the radiating power of the wire, and the cooling effect of the atmosphere, more efficient from the ad-

mixture of inflammable air, prevent it from ever arriving at a temperature equal to that of dull redness. In rapid currents of explosive mixtures of fire-damp, which heat common gause to a higher temperature, twilled-gause, in which the radiating surface is considerably greater, and the circulation of air less, preserves an equable temperature. Indeed, the heat communicated to the wire by combustion of the fire-damp in wire-gause lamps, is completely in the power of the manufacturer. By diminishing the apertures, and increasing the mass of metal, or the radiating surface, it may be diminished to any extent. Thick twilled gause, made of wires one-fortieth, sixteen to the warp, and thirty to the weft, rivetted to the screw to prevent the possibility of displacement, forms a lamp cage, which, from its flexibility, cannot be broken, and from its strength cannot be crushed, except by a very violent blow. The lamp which has been found most convenient for the miner, is that composed of a cylinder of strong wire-gause, fastened round the flame by a screw, and in which the wick is trimmed by a wire passing through a safe aperture. Such have now been used for many years, in the most dangerous mines of England, without any accident. Whatever explosive disasters have happened since, may be imputed to the neglect, or gross and culpable mismanagement, of that infallible protector. See COAL.

‘5. We have now arrived at the most curious of all Sir H.’s discoveries relative to fire, namely, invisible combustion. On passing mixtures of hydrogen and oxygen through tubes heated below redness, steam appeared to be formed without any combustion. This led him to expose mixtures of oxygen and hydrogen to heat, in tubes, in which they were confined by fluid fusible metal. He found, that by carefully applying a heat between the boiling point of mercury, which is not sufficient for the effect, and a heat approaching to the greatest heat that can be given without making glass luminous in darkness, the combination was effected without any violence, and without any light; and commencing with 212, the volume of steam formed at the point of combination appeared exactly equal to that of the original gases. So that the first effect, in experiments of this kind, is an expansion, afterwards a contraction, and then the restoration of the primitive volume. When this change is going on, if the heat be quickly raised to redness, an explosion takes place, with small quantities of gas, the invisible combustion is completed in less than a minute. It is probable that the slow combination without combustion, long ago observed with respect to hydrogen chlorine, oxygen and metals, will happen at certain temperatures with most substances that unite by heat. On trying charcoal, he found, that at a temperature which appeared to be a little above the boiling point of quicksilver, it converted oxygen pretty rapidly into carbonic acid, without any luminous appearance; and at a dull red heat, the elements of olefiant gas combined in a similar manner with oxygen slowly and without explosion. The effect of the slow combination of oxygen and hydrogen is not connected with their rarefaction by heat

for it took place when the gases were confined in a tube by fusible metal, rendered solid at its upper surface; and certainly as rapidly, and without any appearance of light. As the temperature of flame has been shown to be infinitely higher than that necessary for the ignition of solid bodies, it appeared probable that, in these silent combinations of gaseous bodies, when the increase of temperature may not be sufficient to render the gaseous matters themselves luminous, yet it still might be adequate to ignite solid matters exposed to them.

‘Sir H. Davy had devised several experiments on this subject. He had intended to expose fine wires to oxygen and olefiant gas, and to oxygen and hydrogen, during their slow combination under different circumstances, when he was led, accidentally, to the knowledge of the *fact*, and at the same time to the discovery, of a new and curious series of phenomena. He was making experiments on the increase of the limits of the combustibility of gaseous mixtures of coal gas and air, by increase of temperature. For this purpose a small wire-gause safe-lamp, with some fine wire of platinum fixed above the flame, was introduced into a combustible mixture, containing the maximum of coal gas. When the inflammation had taken place in the wire-gause cylinder he threw in more coal gas, expecting that the heat acquired by the mixed gas, in passing through the wire-gause, would prevent the excess from extinguishing the flame. The flame continued for two or three seconds after the coal gas was introduced; and, when it was extinguished, that part of the wire of platinum which had been hottest remained ignited, and continued so for many minutes. When it was removed into a dark room it was evident that there was no flame in the cylinder. It was immediately obvious that this was the result which he had hoped to attain by other methods, and the oxygen and coal gas in contact with the hot wire combined without flame, and yet produced heat enough to preserve the wire ignited and keep up their own secret combustion. The truth of this conclusion was proved by introducing a heated wire of platinum into a similar mixture. It immediately became ignited nearly to whiteness, as if it had been in actual combustion itself, and continued glowing for a long while. When it was extinguished the inflammability of the mixture was found to be entirely destroyed. A temperature much below ignition only was necessary for producing this curious phenomenon, and the wire was repeatedly taken out and cooled in the atmosphere till it ceased to be visibly red; yet, when admitted again, it instantly became red-hot. The same phenomena were produced with mixtures of olefiant gas and air, carbonic oxide, prussic gas, and hydrogen; and in this last case with a rapid production of water. The degree of heat could be regulated by the thickness of the wire. When of the same thickness, the wire became more ignited in hydrogen than in mixtures of olefiant gas, and more in mixtures of olefiant gas than in those of gaseous oxide of carbon.

‘When the wire was very fine, as 1-80th of an inch in diameter, its heat increased in very combustible mixtures, so as to explode them.

The same wire, in less combustible mixtures, continued merely bright red, or dull red, according to the nature of the mixture. In mixtures not explosive by flame within certain limits, these curious phenomena took place, whether the air or the inflammable gas was in excess. The same circumstances occurred with certain inflammable vapors. Those of ether, alcohol, oil of turpentine, naphtha, and camphor, have been tried. There cannot be a better mode of illustrating the fact than by an experiment on the vapor of ether or alcohol, which any person may make in a minute. Let a drop of ether be thrown into a cold glass, or a drop of alcohol into a warm one; let a few coils of wire of platinum, of the 1-60th or 1-70th of an inch, be heated at a hot poker or a candle, and let it be brought into the glass: in some part of the glass it will become glowing, almost white-hot, and will continue so as long as a sufficient quantity of vapor and of air remain in the glass. When the experiment on the slow combustion of ether is made in the dark, a pale phosphorescent light is perceived above the wire, which is, of course, most distinct when the wire ceases to be ignited. This appearance is connected with the formation of a peculiar acid volatile substance, possessed of acid properties. The above experiment has been ingeniously varied by sticking loosely on the wick of a spirit-lamp a coil of fine platinum wire, about $\frac{1}{100}$ of an inch in thickness. There should be about sixteen spiral turns, one-half of which should surround the wick, and the other rise above it. Having lighted the lamp for an instant, on blowing it out the wire will become brightly ignited, and will continue to glow as long as any alcohol remains. A cylinder of camphor may be substituted for both wick and spirit. The ignition is very bright, and exhales an odoriferous vapor. With oil of turpentine the lamp burns, invisibly, without igniting the wire; for a dense column of vapor is perceived to ascend from the wire, diffusing a smell by many thought agreeable. By adding essential oils in small quantities to the alcohol, various aromas may be made to perfume the air of an apartment. But the film of charcoal which in this case collects, on the platina coil, must be removed, by ignition over another spirit flame, otherwise the effect ceases after a certain time. The chemical changes in general, produced by slow combustion, appear worthy of investigation. A wire of platinum introduced, under the usual circumstances, into a mixture of prussic gas (cyanogen), and oxygen in excess, became ignited to whiteness, and the yellow vapors of nitrous acid were observed in the mixture. In a mixture of olefiant gas, non-explosive from the excess of inflammable gas, much carbonic oxide was formed. Platinum and palladium, metals of low conducting powers, and small capacities for heat, alone succeed in producing the above phenomena. A film of carbon or sulphur deprives even these metals of this property. Thin laminæ of the metals, if their form admits of a free circulation of air, answer as well as fine wires; and a large surface of platinum may be made red-hot in the vapor of ether, or in a combustible mixture of coal gas and air.

‘Sir H. Davy made an admirable practical

application of these new facts. By hanging some coils of fine platinum wire, or a fine sheet of platinum or palladium, above the wick of the safe-lamp in the wire-gause cylinder, he has supplied the coal-miner with light in mixtures of fire-damp no longer explosive. Should the flame be extinguished, by the quantity of fire-damp, the glow of the platinum will continue to guide him; and, by placing the lamp in different parts of the gallery, the relative brightness of the wire will show the state of the atmosphere in these parts. Nor can there be any danger, with respect to respiration, wherever the wire continues ignited; for even this phenomenon ceases when the foul air forms about two-fifths of the volume of the atmosphere. Into a wire-gause safe-lamp a small cage of fine wire of platinum, of 1-70th of an inch in thickness, was introduced, and fixed by means of a thick wire of platinum, about two inches above the lighted wick. This apparatus was placed in a large receiver, in which, by means of a gas-holder, the air could be contaminated to any extent with coal gas. As soon as there was a slight admixture of coal gas the platinum became ignited. The ignition continued to increase till the flame of the wick was extinguished, and till the whole cylinder became filled with flame. It then diminished. When the quantity of coal gas was increased, so as to extinguish the flame, the cage of platinum, at the moment of extinction, became white-hot, presenting a most brilliant light. By increasing the quantity of the coal gas still further, the ignition of the platinum became less vivid. When its light was barely sensible small quantities of air were admitted, and it speedily increased. By regulating the admission of coal gas and air it again became white-hot, and soon after lighted the flame in the cylinder, which as usual, by the addition of more atmospheric air, rekindled the flame of the wick.

‘This beautiful experiment has been very often repeated, and always with the same results. When the wire for the support of the cage, whether of platinum, silver, or copper, was very thick it retained sufficient heat to enable the fine platinum wire to rekindle in a proper mixture, half a minute after its light had been entirely destroyed by an atmosphere of pure coal gas. The phenomenon of the ignition of the platinum takes place feebly in a mixture consisting of two of air and one of coal gas; and brilliantly in a mixture consisting of three of air and one of coal gas. The greater the quantity of heat produced, the greater may be the quantity of the coal gas, so that a large tissue of wire made white-hot will burn in a more inflammable mixture (that is containing more inflammable gas) than one made red-hot. If a mixture of three parts of air and one of fire-damp be introduced into a bottle, and inflamed at its point of contact with the atmosphere, it will not explode, but will burn like a pure inflammable substance. If a fine wire of platinum, coiled at its end, be slowly passed through the flame, it will continue ignited in the body of the mixture, and the same gaseous matter will be found to be inflammable, and to be a supporter of combustion. When a large cage of wire of platinum is introduced into a very small

safe-lamp, even explosive mixtures of fire-damp are burned without flame; and, by placing any cage of platinum in the bottom of the lamp round the wick, the wire is prevented from being smoked. Care should be taken, of course, that no filament of the platinum protrude through the wire-gause. It is truly wonderful that a slender tissue of platinum, which does not cost one shilling, and which is imperishable, should afford in the dark and dangerous recesses of a coal-mine, a most brilliant light, perfectly safe in atmospheres in which the flame of the safety-lamp is extinguished; and which glows in every mixture of carburated hydrogen gas that is respirable. When the atmosphere becomes again explosive the flame is relighted. It is no less surprising, that thus also we can burn any inflammable vapor, either with or without flame, at pleasure, and make a slender wire consume it, either with a white or red heat.’

COMBUSTION, SPONTANEOUS. The spontaneous combustion of the human body is a topic of singular interest, and great scientific curiosity. When we reflect on the great quantity of wood or coals required for the burning of a dead human body, and the slowness with which this process is effected, its spontaneous occurrence, and rapid completion in the living body, at a mean temperature, and without the sensible intervention of any ignited material, is a circumstance not lightly to be credited. Nothing, however, is more certain than that such a phenomenon does take place; and, to philosophy, the contemplation of it is highly interesting. Accidents of this kind, indeed, involve many important questions: the character or life of an innocent person may be implicated in their investigation. Hence arises the necessity of acquiring precise knowledge respecting their nature, so that we may not rashly attribute to premeditated crime, the consequences resulting from a very different cause.

This remark is illustrated by the history of a man, whose wife perished at Rheims, in 1725, by the mysterious operation of spontaneous combustion. Her remains were discovered in the kitchen, about a foot and a-half from the fire-place: some parts of the head and lower limbs only, with a few of the joints of the back-bone, had escaped the conflagration. A young and handsome female lived in the house, and horrible suspicions were awakened against the husband, who underwent all the rigor of a criminal prosecution. He appealed from his first sentence; and, in the interval, the woman's death was ascertained to have been occasioned by spontaneous combustion: the unfortunate man, in consequence, was delivered at once from infamy and the scaffold.

It is unnecessary to revert for facts demonstrative of spontaneous combustion, to those remote periods when the mind, credulous from its ignorance of the physical sciences, blindly admitted the reality of appearances the most strange and incredible: later times have exhibited instances of it, sufficiently numerous and authentic to dissipate every doubt respecting its actual occurrence. In attempting to explain these, it is proper to bear in view, that they take place in the living body; and, consequently, that we

must banish all explanations founded exclusively on the physical and chemical laws which regulate inanimate bodies.

From the observations already on record, it appears, that almost all the victims of spontaneous combustion were addicted to the use of strong spirits. Hence, it has been concluded, that the different parts of the bodies of such persons had undergone an alcoholic impregnation, and thus contracted a degree of combustibility sufficient to render them easily inflammable. This opinion seems, at first sight, to be supported by the dissection of persons who have died of intoxication, and whose bodies gave out a spirituous odor. It has been remarked, also, that the flame in these combustions exactly resembles burning spirits; that the individuals to whom this accident happens, were commonly very fat or very thin; and that, in the former case, the fat supports the flame, while in the latter, combustion is supported by the deficiency of moisture. But, on the other hand, can we, in sound physiology, admit the assimilation of any given substance, without its first undergoing certain changes? Vitality, or the living principle, destroys some combinations, and forms others. This faculty may, indeed, be modified by disease; yet it never entirely ceases but with life. We may even regard, as characteristic of vital action, the power it possesses of forming bodies more complicated than the products of inorganic nature. By this action are frequently modified the substances which come to it from the external world; and it then produces bodies, regarded by chemists as incapable of decomposition. Calcareous earth has been obtained from cones of pine growing upon a barren sand, which contained not one atom of that substance; and vegetables yield earthy constituents which form no part of the soil that gives them nourishment. Certain substances, nevertheless, preserve some of their properties after being assimilated, such as color and odor. Madder, when taken into the stomach, reddens the bones; log-wood communicates to the urine a red, and rhubarb a yellow tinge. Agaric, with which the natives of Kamtschatka intoxicate themselves, imparts its inebriating quality to their urine; and, by frictions with garlic, the breath is impregnated with the smell of this vegetable. But, it may be asked, are these substances really in the same state of combination, wherein they existed previously to their being submitted to digestion or absorption? Even on the supposition that alcohol might traverse the animated body, as it soaks a sponge, would not its extreme affinity for water oppose an insurmountable obstacle to its combustion? Do not, moreover, the inflammable eructations sometimes observed in gin-drinkers, show that the spirituous liquor has already undergone some modification in the stomach; since the vapor of ardent spirits is not susceptible of taking fire by simple contact with the atmosphere. Anatomical inspection of dead bodies does not afford inferences more conclusive, provided the gin, taken abundantly a short time before death, has not penetrated their structure, when that structure could no longer offer any vital resistance to its progress. This last supposition is confirmed by

the dissection of several gin-drinkers of both sexes, in whom no alcoholic odor, but inflammation of the stomach, could be detected. No weight, in fine, can be allowed to the resemblance of the flame, in human combustions, to that of burning alcohol, since it is common also to other inflammable substances, as hydrogen gas, and its combinations with carbon and sulphur. To these objections, may be added the fact, that intemperance cannot be imputed to all those persons, without exception, who have perished from spontaneous combustion. As to the state of corpulence or emaciation, it will be invariably found that the fat of the body is never sufficiently deprived of its aqueous part, and the wasting never sufficiently decided, to admit the supposition of a degree of dryness favorable to rapid conflagration.

When the different cases of spontaneous human combustion have been classified, for the purpose of deducing general conditions from them, it will be found, 1. That women are much more subject to it than men; now, it is evident, that the skin and cellular membrane of females are more tender and lax than those of man, and that women are more disposed to corpulence. 2. That spontaneous combustion has commonly occurred in aged persons, almost all those who have perished from it being past their sixtieth year. 3. That, independently of the state of debility proper to such age, these persons had suffered from particular debilitating affections, 4. That their debility must still further have been augmented by the circumstances of an inactive life. 5. That many among them were corpulent: now, corpulence, at an advanced age, almost invariably implies a relaxed state, particularly of the system called lymphatic; hence dropsy and constitutional infirmity are very common in such persons. 6. That the greater number of the victims of spontaneous combustion, were addicted to the use of ardent spirits, 7. That, near the place of the catastrophe, has almost constantly been found an ignited body of some kind, however small, as a lamp, or burning coals. 8. That the conflagration has been exceedingly rapid, and gained every part of the body ere succour could arrive. 9. That the flame was very light and unsteady, difficult of extinction by water; and only attacked the combustible substances around, when remaining for a considerable time in contact with them. 10. That the place where the combustion happened, exhaled a strong empyreumatic odor; and that the walls, ashes, and cinders, were covered with a fetid moisture and with fat. 11. That the trunk of the body, with the exception of a few bones, was commonly consumed; and that there remained, in most cases, a portion of the head and extremities, more or less considerable: and, 12. That, in the majority of these instances, the accident has taken place at a low temperature of the atmosphere, consequently in winter.

For a correct explanation of the singular appearances now under consideration, it will be necessary, first of all, to distinguish the combustibility from the combustion itself, or, in other words, the cause exciting it. The combustibility of the human body becomes here, as we may

suppose, a peculiar condition; since, in the healthy state, it ranks in the class of substances most difficultly combustible. This combustibility, then, is determined by the debility consequent upon age, diseases, bodily inactivity, and intemperance. The abuse of strong liquors, especially gin, debilitates the absorbent system in a signal degree; and this state may give rise, in certain cases, to the formation of a mass of substance, alike inflammable and susceptible of accumulating, in greater or less quantity, in different parts of the body, according to their different structure. The combustible substance ought, therefore, to possess the property of penetrating easily into the interstices of the body, and of losing nothing of its combustibility by contact with liquids. These conditions are, in no class of substances, better combined than in the inflammable gases; nor, independently of them, can the fact now claiming attention, be well explained. It is necessary, therefore, for the production of the spontaneous combustion, that an inflammable gas accumulate in the cells of the cellular membrane, as the fluid of dropsy is accumulated; and, without admitting the pre-existence of the whole quantity of gas requisite for the completion of the process, it may reasonably be supposed that it terminates in giving rise to a fresh extrication of gas from those parts of the burning body surcharged with hydrogen. By this theory is obviated the objection which the absence of a previously emphysematous state in the victims of spontaneous combustion has suggested; with some among them, however, this state seems really to have existed.

Hydrogen constitutes one of the principal elements of the animal body, and combinations the most various are there formed by it with caloric, carbon, sulphur, and phosphorus: after death, as in life, its presence is unequivocally detected. It may be useful, in this place, to review the different phenomena which, in demonstrating that truth, connect it most intimately with the subject of spontaneous human combustion. A flame was observed to issue from the skin of a pig, at the moment of its being cut into with a knife; and two eminent anatomists saw a vapor exhaling from the stomach of a woman whom they had just opened: it took fire on the approach of a lighted candle. A similar fact also occurred in examining the stomach of another female, who, in the four days preceding her death, had taken no food. In some other cases, the gas inflamed without the intervention of any ignited body, merely by contact with the atmosphere. On the opening of an ox, which had been for some time sick, an explosion took place, and flame bursting from the stomach, to the height of more than five feet, scorched the butcher, as well as a little girl who stood beside him. It lasted several minutes, and gave out a most disgusting odor. The production of hydrogen gas, during life, cannot be doubted. It is known to be daily extricated in the bowels, and observations analogous to these just enumerated are by no means rare. Inflammable eructations frequently occur, particularly in northern regions, where persons, after an immoderate indulgence in gin, have been exposed to a cold

atmosphere. Some years since, an accident of this kind befel a Bohemian peasant: he died in the presence of many witnesses, from a column of air taking fire upon its extrication from the stomach, and baffling all the ordinary means of extinction. In such cases, the decomposition of alcohol, and of animal substance contained in the stomach, has generated a quantity of phosphureted hydrogen, which instantly inflames upon contact with atmospheric air. This process, however, extends no farther; because the other parts of the body do not possess the conditions requisite for a more general conflagration.

Since, then, we cannot deny that the inflammable gases are developed in the human body, it cannot surely be going too far to admit their occasional accumulation in the cellular structure, in quantity proportioned to the laxity of that structure. Hence, it happens that the softest parts, and consequently the trunk, are most subject to these gaseous accumulations. But the human body, thus rendered highly combustible, cannot yet take fire without the intervention of an inflaming spark; for, even admitting that part of the inflammable principle consists of phosphureted hydrogen gas, we are unable to explain adequately, and in all cases, the general conflagration which ensues. By some, the presence of ignited bodies has been considered as the cause of this catastrophe; and others even assert that, strictly speaking, what really originates in accident, cannot be called spontaneous combustion. We are unable, however, from this view of the subject, to conceive how the burning should be so rapid, general, and complete, as it commonly is; and still less, on what part of the body it is first manifested. Instances of human combustion, moreover, have occurred, in which the presence of no ignited body could be suspected. In comparing these various considerations, with the fatal accident detailed in the subsequent history, the mind is led to regard electricity as exerting considerable influence in human combustion, or even as the occasional cause of this extraordinary phenomenon.

No one can doubt, for a moment, the ideoelectricity of many animals; and this state exists, in a very remarkable degree, with many individuals of the human species. Experiments were made, during a severe frost, upon a woman whose ideoelectricity was such, that sparks issued from her hair as often as it was combed: a Leyden phial was even charged, and alcohol inflamed, with these sparks. Sparks of electricity, indeed, have often been emitted from stockings of wool and silk, when being taken off the limbs: examples of this kind might be multiplied to an indefinite extent. Inflammable substances, accumulated in the bodies of those who have perished from spontaneous combustion, must, by their nature, increase the electric state. Warmth will equally favor the explosion of the inflaming sparks. Thus, the proximity of fire or a lighted candle may, in some instances, have aided the process of human combustion: in others, the same effect may have been produced by violent exercise or other causes capable of exciting electricity. The electric spark, thus developed, tra-

verses with extreme rapidity, bodies in any way impregnated with inflammable matter; and the latter, taking fire upon every point, can no longer be quenched by the fluid parts. Thus, the burning usually proceeds with such celerity, that the miserable victim has no time to call for assistance. The flame, as is proved by observation, at first spreads upon the surface of the body; because there, in contact with the air of the atmosphere, it is fitted to support combustion: it is subsequently propagated to the more deep-seated parts. This theory will explain, without difficulty, the following circumstances already alluded to, and which we again detail with their reasons.

I. Women are more subject than men to spontaneous combustion, because their more relaxed structure is favorable to gaseous accumulations.

II. Spontaneous combustion most frequently takes place in aged persons; because such are more addicted than the young to the use of ardent spirits; they employ less exercise; and their vital energy, particularly that of the lymphatic system, is weaker.

III. The characters of the flame, its lightness, mobility, and resistance to the action of water, are those of hydrogen gas. The natural phenomena in the production of which this gas enjoys a principal share, as *ignes fatui* and certain meteors, exhibit similar appearances.

IV. The furniture and other surrounding objects are, on these occasions, little damaged; because hydrogen gas, in combustion, implicates the generality of combustible bodies, only when remaining in intimate contact with them.

V. The moisture which invariably covers the walls where the conflagration takes place, as well as the charred relics of the body, is furnished by the combustion of the hydrogen gas, and also by the evaporation of the liquids of the body itself. The oily appearance of it arises from the fat which the heat has fused; and the fætid odor proceeds from the empyreumatic oil.

VI. The trunk of the body has always suffered more from this kind of combustion than other parts; this circumstance is explained by the size of its cavities, and the looseness of their cellular structure: and,

VII. Winter is the season in which spontaneous human combustion most frequently occurs; because the cold air, which is a bad conductor of electricity, favors the ideo-electric state of the animal body.

This view of its nature is founded on inductions afforded by many (more than 100) well authenticated histories of spontaneous human combustion, recorded by diligent and faithful observers, in very different eras and countries. There would be little propriety, however, in swelling the present article by unnecessary extracts from these: yet there is one which possesses extraordinary interest, as the subject of it, having survived the accident for a time, was enabled to give an account of the various circumstances by which it was preceded and followed. The case was published in one of the Journals of Florence, for October, 1776, by Mr. Battaglia, the surgeon who attended the unfortunate sufferer. It is related nearly in the following terms:—

‘Gio Maria Bertholi, resident priest at Monte Volere, went on business to a neighbouring fair; and, having spent the day in walking about the country, arrived in the evening at Femile, intending to sleep at the house of his brother-in-law. Immediately on his arrival, he was conducted to his chamber at his own request, when he had a handkerchief placed between his shirt and shoulders; and, being now left alone, he betook himself to his devotions. Scarcely had a few minutes elapsed, when an uncommon noise, mingled with cries, was heard issuing from his apartment. The people of the house were alarmed; and rushing in, found the priest stretched upon the floor, and surrounded by a light flame, which receded as they approached, and ultimately vanished. He was instantly placed in bed, and on the following morning visited by the surgeon, who, on examination, found the skin of the right arm and fore-arm detached from the muscles, and hanging loose. From the shoulders to the thighs, the integuments were similarly injured. These detached portions of skin having been altogether removed; and, mortification being perceived on the right hand, which had suffered most severely, the parts were scarified. Notwithstanding this precaution, it had fallen by the next day into a state of complete gangrene. On the third day, all the other scorched parts were discovered to have degenerated into the same condition. The unhappy man complained of unquenchable thirst, and was horribly convulsed. The discharges from his bowels were putrid and bilious, and his strength was exhausted by continual vomitings, accompanied with delirium, and a burning fever. After lying two hours in a state of insensibility, he expired on the fourth day. While he lay in this lethargic sleep, his attendant observed, with astonishment, that putrefaction had made considerable progress, so that the body exhaled an intolerable odor: worms crawled from it on the bed, and the nails were spontaneously detached from the fingers of the left hand.

‘This unfortunate man informed the surgeon that first of all he had felt a blow, like that inflicted by a cudgel, upon the right arm; and that, at the same moment, he saw a light blue flame attach itself to his shirt, which was instantaneously reduced to ashes; yet his wrist-bands, at the same time, remained utterly untouched. The handkerchief, which, as formerly mentioned, had been introduced between his shoulders and shirt, was entire and free from every trace of burning. His drawers and breeches had equally escaped; but his cap was entirely consumed, although not a hair of his head had suffered from the flame. That this flame, says Mr. Battaglia, dispersed under the form of elementary fire, had destroyed the skin, and reduced the shirt and cap to ashes, without implicating the hair of the head, is a fact which I most confidently assert. Moreover, all the symptoms of the disease were those of a severe burn. The night of the accident was calm; the atmosphere very clear; no empyreumatic or bituminous smell; no appearance of smoke was perceived in the chamber; but the lamp, before full of oil, was become dry, and its wick reduced to a cinder.’ Such is the outline of this very

singular history, the chief incidents of which seem quite irreconcilable with the pre-conceived views of mankind. By minds peculiarly constructed, or habituated to peculiar modes of reflecting, it will consequently be regarded as needing a more than ordinary degree of testimony for its support. But it ought to be remembered that we have no more pre-conceived cause for doubting or believing the spontaneous combustion of the materials composing the human body, than of any other substances, simple or compound, in the material world around us. The reality of its occurrence, therefore, must be determined by the evidence of facts alone, and not by pre-conceived views: this, as well as all cases of the same kind have, with some minute shades of difference, been attended with the same characteristic appearances,—a fact which, independently of all other testimony, should be admitted as affording internal evidence of their authenticity.

COME, *v. n.*, pret. came; participle, come. Sax. *coman*; Dutch, *comen*; German *kommen*. Opposed to go, to remove from a distant to a near place; to draw near, to advance towards, to move in any manner towards another; implying the idea of being received by another, or of tending towards another. The word always respects the place to which the motion tends, not that place which it leaves; yet this meaning is sometimes almost evanescent and imperceptible. To advance from one stage or condition to another. After giving no fewer than sixty varieties of meaning or applications of this word, Dr. Johnson remarks:—Come is a word of which the use is various and extensive, but the radical signification of tendency hitherward is uniformly preserved. When we say he came from a place, the idea is that of returning, or arriving, or becoming nearer; when we say, he went from a place, we conceive simply departure, or removal to a greater distance. The butter comes; it is passing from its former state to that which is desired; it is advancing towards us. As far as each of these varieties is distinct and definite, we now present them in their proper order, with the illustrations annexed:

And troubled blood through his pale face was seen,
To come and go, with tidings from the heart.

Fairie Queene.

Cæsar will come forth to-day.

Shakspeare. Julius Cæsar.

Coming to look on you, thinking you dead,
I speak unto the crown as having sense.

Id. Henry IV.

The colour of the king doth come and go,
Between his purpose and his conscience.

Id. King John.

By the pricking of my thumbs,
Something wicked this way comes. *Id. Macbeth.*

Though he would after have turned his teeth upon Spain, yet he was taken order with before it came to that.

Bacon.

Seditious, tumults, and seditious fames, differ no more but as brother and sister; if it come to that, that the best actions of a state are taken in an ill sense and traduced.

Id.

It is reported, that if you lay good store of kernels

of grapes about the root of a vine, it will make the vine come earlier, and prosper better.

Id. Natural History.

Then butter does refuse to come.

And love proves cross and humoursome. *Hudibras.*

To COME, to attain any condition or character.

A serpent ere he comes to be a dragon,

Does eat a bat.

Ben Jonson's Cataline.

He wondered how she came to know

What he had done and meant to do.

Hudibras.

The testimony of conscience, thus informed, comes to be so autentic, and so much to be relied upon.

South.

To become.

So came I a widow;

And never shall have length of life enough

To rain upon remembrance with mine eyes.

Shakspeare. Henry IV.

When he returns from hunting,

I will not speak with him; say I am sick.

If you come slack of former services,

You shall do well.

Id. King Lear.

How came the publican justified, but by a short and humble prayer?

Duupa's Rules for Devotion.

To arrive at some act, or habit, or disposition.

They would quickly come to have a natural abhorrence for that which they found made them slighted.

Locke.

To become present, and no longer future.

But home he goth, he mighte not sojourne.

The day was come that homeward he must turne.

Chaucer's Canterbury Tales.

Learn to be well, or fairly make your will,

You've played, and loved, and ate and drank your fill,

Walk sober off before a sprightlier age

Comes trittering on and shoves you from the stage.

Pope.

In his lair,

Fixed passion holds his breath, until the hour

Which shall atone for years; none need despair:

It came, it cometh, and will come—the power

To punish or forgive—in one we shall be slower.

Byron's Childe Harold.

To become present, and no longer absent.

Come then, come soone, come sweetest death to me,

And take away this long-lent loathed light:

Sharpe be thy wounds, but sweete the medicines be

That long captived souls, from weary thraldom free.

Spenser.

Come after them, for haply in my bower,

Amusement, knowledge, wisdom, thou may'st gain,

If I one soul improve, I have not lived in vain.

Beattie.

Borne on the swift, though silent wings of time,

Old age comes on apace to ravage all the clime. *Id.*

No dread of death, if with us die our foes,

Save that it seems even duller than repose:

Come when it will—we snatch the life of life,

When lost—what reeks it—by disease or strife.

Byron.

To happen; to fall out.

The duke of Cornwall and Regan his duchess, will be here with him this night.—

—How comes that? *Shakspeare. King Lear.*

To befall as an event.

Let me alone that I may speak, and let come on me what will.

Job xiii. 13.

To follow as a consequence.

Those that are akin to the king, never prick their fingers but they say, there is some of the King's blood

split. How comes that? says he, that takes upon him not to conceive; the answer is, I am the king's poor cousin, Sir.
Shakspeare. Henry IV.

To come about. To come to pass; to fall out; to come into being. Probably from the French *venir a bout*.

And let me speak to the yet unknowing world, how these things came about.
Shakspeare.

That cherubim, which now appears as a God to the human soul, knows very well that the period will come about in eternity, when the human soul shall be as perfect as he himself now is.
Addison's Spectator.

To come about. To change; to come round.

The wind came about, and settled in the west for many days.
Bacon's New Atlantis.

On better thoughts, and my urged reasons, They are come about, and won to the true side.

Ben Jonson.

To come again. To return.

There came water therout; and when he had drunk, his spirit came again, and he revived.

Judges, xv. 19.

To come after. To follow.

If any man will come after me, let him deny himself, and take up his cross and follow me.

Matthew, xvi. 24.

To come at. To reach; to get within the reach of; to obtain; to gain.

Neither sword nor sceptre can come at conscience; but it is above and beyond the reach of both.

Suckling.

Cats will eat and destroy your marum, if they can come at it.

Evelyn's Kalendar.

In order to come at a true knowledge of ourselves, we should consider how far we may deserve praise.

Addison.

To come by. To obtain; to gain; to acquire. This seems an irregular and improper use, but has very powerful authorities.

Things most needful to preserve this life, are most prompt and easy for all living creatures to come by.

Hooker.

Love is like a child,

That longs for every thing that he can come by.

Shakspeare.

To come in. To comply; to yield; to hold out no longer.

If the arch-rebel Tyrone, in the time of these wars, should offer to come in and submit himself to her majesty, would you not have him received?

Spenser on Ireland.

To come in. To become modish; to be brought into use.

Then came rich cloaths and graceful action in, Then instruments were taught more moving notes.

Roscommon.

Silken garments did not come in till late, and the use of them in men was often restrained by law.

Arbutnot on Coins.

To come in. To be an ingredient; to make part of a composition.

A generous contempt of that in which too many men place their happiness, must come in to heighten his character.

Atterbury.

To come in. To accrue from an estate, trade, or otherwise, as gain.

I had rather be mad with him that when he had nothing, thought all the ships that came into the harbour his; than with you that, when you have so much coming in, think you have nothing.

Suckling.

To come in. To be gained in abundance.

Sweetheart, we shall be rich ere we depart, If fairings come thus plentifully in.

Shakspeare.

To come in for. To be early enough to obtain; taken from hunting, where the dogs that are slow get nothing.

Shape and beauty, worth and education, wit and understanding, gentle nature and agreeable humour, honor and virtue, were to come in for their share of such contracts.

Temple.

If thinking is essential to matter, stocks and stones will come in for their share of privilege.

Collier on Thought.

One who had in their rear excluded been, And could not for a taste o' th' flesh come in, Licks the solid earth.

Tate's Juvenal.

The rest came in for subsidies, whereof they sunk considerable sums.

Swaift.

To come in to. To join with; to bring help.

They marched to Wells, where the lord Audley with whom their leaders had before secret intelligence, came in to them; and was by them, with great gladness and cries of joy, accepted as their general.

Bacon's Henry VII.

To come into. To comply with; to agree to. The fame of their virtues will make men ready to come into every thing that is done for the public good.

Atterbury.

To come near. To approach; to resemble in excellence; a metaphor from races.

Whom you cannot equal or come near in doing, you would destroy or ruin with evil speaking.

Ben Jonson's Discoveries.

To come of. To proceed, as a descendant from ancestors.

Of Priam's royal race my mother came.

Dryden's Æneid.

Self-love is so natural an infirmity, that it makes us partial even to those that come of us, as well as ourselves.

L'Estrange.

To come of. To proceed as effects from their causes.

Will you please, Sir, be gone;

I told you what would come of this.

Shakspeare. Winter's Tale.

The hicough comes of fullness of meat, especially in children, which causeth an extension of the stomach.

Bacon.

To come off. To deviate; to depart from a rule or direction.

The figure of a bell partaketh of the pyramids, but yet coming off and dilating more suddenly.

Bacon's Natural History.

To come off. To escape; to get free.

I knew the foul enchanter, though disguised; Entered the very lime-twigs of his spells,

And yet came off.

Milton.

How thou wilt here come off, surmounts my reach.

Id.

If, upon such a fair and full trial, he can come off, he is then clear and innocent

South.

To come off. To end an affair; to take good or bad fortune.

Oh, bravely came we off,

When with a volley of our needless shot, After such bloody toil, we bid good night.

Shakspeare. King John.

Ever since Spain and England have had any thing to debate one with the other, the English, upon all encounters, have come off with honor and the better.

Bacon.

To come off from. To leave; to forbear.

To come off from these grave disquisitions, I would clear the point by one instance more.

Felton on the Classics

To come on. To advance; to make progress. Things seem to *come on* apace to their former state.

Bacon.

There was in the camp both strength and victual sufficient for the obtaining of the victory, if they would not protract the war until winter were *come on*.

Knolles's History.

To come on. To advance to combat.

The great ordnance once discharged, the armies *came fast on*, and joined battle.

Knolles's History of the Turks.

Rhymer, *come on*, and do the worst you can; I fear not you, nor yet a better man.

Dryden.

To come on. To thrive; to grow big; to grow.

Come on, poor babe;

Some powerful spirit instruct the kites and ravens
To be thy nurses.

Shakspeare. Winter's Tale.

It should seem by the experiments, both of the malt and of the roses, that they will *come far* faster on in water than in earth; for the nourishment is easier drawn out of water than out of earth.

Bacon's Natural History.

To come over. To revolt.

They are perpetually teasing their friends to *come over* to them.

Addison's Spectator.

A man, in changing his side, not only makes himself hated by those he left, but is seldom heartily esteemed by those he *comes over* to.

Id.

To come over. To rise in distillation.

Perhaps also the phlegmatic liquor, that is wont to *come over* in this analysis, may, at least as to part of it, be produced by the operation of the fire.

Boyle.

To come out. To be made public; to appear upon trial; to be discovered.

Before his book *came out*, I had undertaken the answer of several others.

Stillingfleet.

It is indeed *come out* at last that we are to look on the saints as inferior deities.

Id.

I have been tedious; and, which is worse, it *comes out* from the first draught, and uncorrected.

Dryden.

To come out with. To give a vent to; to let fly.

Those great masters of chymical arcana must be provoked, before they will *come out with* them.

Boyle.

To come to. To consent or yield.

What is this, if my parson will not *come to*?

Swift.

To come to. To amount to.

The emperor imposed so great a custom upon all corn to be transported out of Sicily, that the very customs *came to* as much as both the price of the corn and the freight together.

Knolles's History of the Turks.

You saucily pretend to know

More than your dividend *comes to*.

Hudibras.

Animals either feed upon vegetables immediately, or, which *comes to* the same at last, upon other animals which have fed upon them.

Woodward's Natural History.

He pays not this tax immediately, yet his purse will find it by a greater want of money than that *comes to*.

Locke.

To come to himself. To recover his senses.

He falls into sweet ecstasy of joy, wherein I shall leave him till he *comes to himself*.

Temple.

To come to pass. To be effected; to fall out.

It *cometh*, we grant, many times to *pass*, that the works of men being the same, their drifts and purpose therein are divers.

Hooker.

How *comes it to pass*, that some liquors cannot pierce into or moisten some bodies, which are easily pervious to other liquors?

Boyle's History of Firmness.

To come up. To grow out of the ground.

Over-wet, at sowing-time, with us breedeth much dearth, insomuch as the corn never *cometh up*.

Bacon.

If wars should mow them down never so fast, yet they may be suddenly supplied, and *come up* again.

Id.

Good intentions are the seeds of good actions; and every man ought to sow them, whether they *come up* or no.

Temple.

To come up. To come up into use; as a fashion comes up.

To come up to. To rise; to advance.

Whose ignorant credulity will not
Come up to the truth.

Shakspeare. Winter's Tale.

Considerations there are, that may make us, if not *come up to* the character of those who rejoice in tribulations, yet at least satisfy the duty of being patient.

Wake's Preparation for Death.

To come upon. To invade; to attack.

Three hundred horse, and three thousand foot, English, commanded by Sir John Norris, were charged by Parma, *coming upon* them with seven thousand horse.

Bacon.

When old age *comes upon* him, it comes alone, bringing no other evil with it but itself.

South.

To come. In futurity; not present; to happen hereafter.

It serveth to discover that which is hid, as well as to foretel that which is *to come*.

Bacon's Natural History

In times *to come*,

My waves shall wash the walls of mighty Rome.

Dryden.

COME. Participle of the verb.

Thy words were heard, and I am *come* to thy words.

Daniel.

COME. A participle of exhortation; be quick; make no delay.

Come, let us make our father drink wine.

Genesis xix. 32.

COME. A participle of reconciliation; or incitement to it.

Come, come, at all I laugh he laughs no doubt;

The only difference is, I dare laugh out.

Pope.

COME. A kind of adverbial word for when it shall come; as, come Wednesday, when Wednesday shall come.

Come Candlemas, nine years ago she died.

Gay.

COME, *n. s.* From the verb. A sprout; a cant term.

That the malt is sufficiently well dried, you may know both by the state, and also by the falling off of the *come* or sprout.

Mortimer's Husbandry.

CO'MER, *n. s.* From come. One that comes.

Time is like a fashionable host,

That slightly shakes his parting guest by the hand;

But with his arms outstretched, as he would fly,
Grasps in the *comer*: welcome ever smiles,
And farewell goes out sighing.

Shakspeare. Troilus and Cressida.

COMING, n. s. From to come. The act of coming; approach.

Where art thou, Adam! went with joy to meet
My coming, seen far off? *Milton's Paradise Lost.*

Sweet the coming on
Of grateful evening mild. *Id.*

State of being come; arrival.

May 't please you, noble Madam, to withdraw
Into your private chamber; we shall give you
The full cause of our coming.

Shakespeare. Henry VIII.

Some people in America counted their years by the coming of certain birds amongst them at their certain seasons, and leaving them at others. *Locke.*

COMING-IN, n. s. Revenue; income.

Here's a small trifle of wives; eleven widows, and nine maids is a simple coming-in for one man.

Shakespeare.

What are thy rents? what are thy comings-in?
O ceremony, show me but thy worth?
What is thy toll, O adoration? *Id. Henry V.*

COMING, particip. adj. From come. Fond; forward; ready to come.

Now will I be your Rosalind in a more coming on disposition; and ask me what you will, I will grant it.

Shakespeare.

That very lapidary himself, with a coming stomach, and in the cock's place, would have made the cock's choice.

L'Estrange.

That he had been so affectionate a husband, was no ill argument to the coming dowager.

Dryden.

On morning wings how active springs the mind!
How easy every labour it pursues,
How coming to the poet every muse! *Pope's Horace.*

Future; to come.

Praise of great acts he scatters, as a seed
Which may the like in coming ages breed.

Roscommon.

COMEDY, n. s. Gr. κωμῆα. A dramatic representation; its avowed intention is to exhibit life and manners, and to correct the foibles and follies of mankind by a natural and ridiculous exhibition of them. It is opposed to tragedy. A comedian is a writer of comedies; an actor of comedies; or a player in general of either sex.

Melissarion, pretty honey-bee, when of a comedian she became a wealthy man's wife, would be saluted Madam Pithias, or Prudence. *Camden's Remains.*

Your honour's players

Are come to play a pleasant comedy.

Shakespeare. Taming of the Shrew.

Scaliger willeth us to admire Plautus as a comedian, but Terence as a pure and elegant speaker.

Peachment of Poetry.

A long, exact, and serious comedy;

In every scene some moral let it teach,

And, if it can, at once both please and preach.

Pope.

The whining tragic love she scarce can bear,
But nauseous comedy ne'er shocked her ear. *Gay.*

COMEDY. The Romans made a subdivision of comedy into ancient, middle, and new, according to the various periods of the commonwealth. Among the ancient comedies were reckoned those of Livius Andronicus; among the middle, those of Pacuvius; and among the new ones, those of Terence. They likewise distinguished comedy according to the quality of the persons

represented, and the dress they wore, into togata, prætectata, trabeata, and tabernaria, which last agrees pretty nearly with our farces. Among us comedy is distinguished from farce, as the former represents nature as she is; the other distorts and overcharges her. They both paint from the life, but with different views; the one to make nature known; the other to make her ridiculous. See POETRY.

COMELY, adj. & adv. From become; or

COMELINESS, n. s. From Sax. cpe-man, to please. Graceful; decent; having dignity or grandeur of mein or look. Comeliness seems to be that species of beauty which excites respect rather than pleasure: it signifies something less forcible than beauty, less elegant than grace, and less light than prettiness. Used of things, decent; according to propriety.

To ride comely, to play at all weapons, to dance comely, be very necessary for a courtly gentleman.

Ascham's Schoolmaster.

The service of God hath not such perfection of grace and comeliness, as when the dignity of the place doth concur.

Hooker.

If the principal part of beauty is in decent motion, no marvel though persons in years seen many times more amiable; for no youth can be comely but by pardon, and considering the youth as to make up the comeliness.

Bacon.

Soon after them all dauncing on a row,
The comely virgins come with girlondz dight,
As fresh as flowres in meadow greene doe grow.

When morning deaw upon their leaves doth light;
And in their hands sweet timbrels all upheld on hight.

Spenser.

Where, when the knight arrived, he was right well
Received, as knight of so much worth became
Of second sister, who did far excell
The other two; Medina was her name,
A sober, sad, and comely courteous dame. *Id.*

They skilled not of the goodly ornaments of poetry,
yet were sprinkled with some pretty flowers, which
gave good grace and comeliness. *Id. on Ireland.*

A careless comeliness with comely care. *Sidney.*

Oh, what a world is this, when what is comely
Envenoms him that bears it.

Shakespeare. As You Like It.

This is a happier and more comely time,
Than when these fellows ran about the streets,
Crying confusion. *Id. Coriolanus.*

He that is comely when old and decrepit, surely
was very beautiful when he was young. *South.*

Hardly shall you meet with man or woman so aged
or ill-favoured, but if you will commend them for
comeliness, nay and for youth too, shall take it well. *Id.*

Thou art a comely, young, and valiant knight.

Dryden.

There is great pulchritude and comeliness of proportion in the leaves, flowers, and fruits of plants.

Ray on the Creation.

A horseman's coat shall hide

Thy taper shape, and comeliness of side. *Prior.*

Now each his mistress toasts, by whose bright eye
He's fired; Cosmelia fair, or Dulcibell,
Or Sylvia, comely black with jetty eyes
Piercing, or any Celia, sprightly maid. *Gay.*

COMENIUS (John Amos), a grammarian and Protestant divine, born in Moravia in 1592. He was eminent for his attempt to introduce a new method of teaching languages; for which purpose

he published some essays in 1616, and had prepared others when the Spaniards pillaged his library, after having taken the city of Fulnec, where he was minister and master of the school. Comenius fled to Lesna, in Poland, where he became a teacher of Latin. His *Janua Linguarum Reserata*, published in 1631, gained him great reputation, insomuch that he was offered a commission for regulating all the schools in Poland, and the parliament of England desired his assistance to regulate the English schools. He arrived at London in 1641; and would have been received by a committee to hear his plan, had not the parliament been then engaged on other more important subjects. He therefore went to Sweden, being invited by a generous patron, who settled a stipend upon him, and he now employed himself wholly in preparing his plans for the instruction of youth. In 1657 he published the different parts of his new method of teaching. He next began to explain the prophecies, the fall of Antichrist, and the commencement of the millennium which he fixed for 1672. He died in 1671 aged eighty.

COMESSAZZO, a town of Italy, in the civedant duchy of Mantua, and department of the Upper Po, two miles and a half north of Sabionetta.

COMET, *n. s.* } Lat. *cometa*. Literally
 Co'METARY, *adj.* } a hairy star. For the
 COME'TIC, *adj.* } scientific description, see
 ASTRONOMY.

And wherefore gaze this goodly company,
 As if they saw some wondrous monument,
 Some comet, or unusual prodigy?

Shakspeare. Taming of the Shrew.

Such his fell glances as the fatal light
 Of staring comets. *Crashaw.*
 I considered a comet, or, in the language of the vulgar, a blazing star, as a sky-rocket discharged by an hand that is almighty. *Addison's Guardian.*

Fierce meteors shoot their arbitrary light,
 And comets march with lawless horrors bright. *Prior.*

Refractions of light are in the planetary and cometary regions, as in our globe, *Cheyne's Phil. Prin.*

Hast thou ne'er seen the comet's flaming flight?
 The illustrious stranger passing, terror sheds
 On gazing nations, from his fiery train
 Of length enormous, takes his ample round
 Through depths of ether; coasts unnumbered worlds
 Of more than solar glory; doubles wide
 Heaven's mighty cape; and then revisits earth,
 From the long travel of the thousand years.

Young's Night Thoughts.

Lo! from the dread immensity of space,
 Returning with accelerated course,
 The rushing comet to the sun descends,
 And as he sinks below the shading earth,
 With awful train projected o'er the heavens
 The guilty nations tremble. *Thomson's Seasons.*

The hour arrived—and it became
 A wandering mass of shapeless flame,
 A pathless comet, and a curse,
 The menace of the universe. *Byron's Manfred.*

COMETS. We have devoted a section of our general article ASTRONOMY to the consideration of the different theories that have been espoused by men of science respecting the nature and orbits of these singular bodies. We know not whether we ought to add to these, the astronomico-theo-

logical reverie of Whiston, who assures us that he has discovered not only the place, but the nature of the punishment of the damned, in these (no longer) heavenly bodies. Whirled from remote regions of the universe into a nearer approach to the sun than other body of the solar system, and then back again into the extremest distance from it, he conceived them to be thus exposed alternately to the most ardent heat and the most benumbing cold. Certainly his conjecture may remind us of the general improbability of such bodies being inhabited by any race of beings like men.

It is remarkable that one of the early conjectures of science respecting these bodies, that they were accidental assemblages of small stars, has been so far revived, or rather perhaps reversed, in modern times, that Dr. Brewster has hazarded an opinion, that the planets Ceres and Pallas, may have derived their immense atmospheres from the explosion of a comet, and fixes upon that of 1770 as having been most probably the comet in question.

This comet was in that year most carefully observed for four months by M. Messier. M. M. Proserpin and Pingré first suspected that its orbit might be elliptical, and M. Lexell of St. Petersburg computed its elements in an elliptical orbit, and found that its period was five years and a half, and its greatest distance from the sun about that of Jupiter. It has, however, never re-appeared. This subject lately attracted the notice of the National Institute of France, at whose request Dr. Burckhardt repeated all the former calculations with great care. 'Here then,' says an able writer in the Encyclopædia of Dr. Brewster, 'is a most singular anomaly in the motion of the comet. While all the other comets which have been observed, move in orbits stretching far beyond the limits of the solar system, and revolve in periods of long duration, the comet of 1770 never wanders beyond the orbit of Saturn, and completes its revolution in the short period of five years and a half. The return of this body, therefore, was confidently expected by astronomers; but though it must now have completed nearly eight revolutions round the sun, and though more observations have been made in the heavens during the last forty years than perhaps during the two preceding centuries, yet the comet of 1770 has never re-appeared. We are consequently entitled to conclude, that the comet of 1770 is lost, which could happen only from its uniting with one of the planets, whose orbits it crossed. Now, if such an union took place, two consequences would obviously flow from it. The planet would suffer a sensible derangement in its motions, and its atmosphere would receive a vast accession of that nebulous matter, of which the comets are often wholly composed. Here, then, we have two distinct criteria to enable us to ascertain the individual planet by which the comet was attracted. The path of the comet intersects the orbits only of Venus, the Earth, Mars, the four new planets, and Jupiter, and therefore it must have united with one of these bodies, or with their satellites. Now, since the year 1770, neither Venus, the Earth, Mars, nor Jupiter, have suffered the smallest derangement of this kind, nor have they

received any visible addition to their atmospheres. We must, therefore, look to the four new planets for some indication of the presence of a comet, and, if they exhibit any phenomena that are unequivocally of this description, we must consider such a coincidence as a strong proof of the theory, or as one of the most wonderful facts in the history of science. Two of the new planets, Ceres and Pallas, exhibit, in the form and position of their orbits, evident marks of some great derangement; they are actually surrounded with atmospheres of an immense size. The atmosphere of Ceres is 675 English miles high, while that of Pallas rises to the height of 468 miles. Now the height of any of these atmospheres is greater than the united heights of the atmospheres of all the other planets, and is above a thousand times higher than they ought to have been, according to the ratio that exists between the globes and atmospheres of the other bodies of our system.' 'Let us enquire,' continues this writer, 'from what other source these atmospheres could be derived, if they were not imparted by the comet of 1770. If the four new planets are the fragments of a larger body, endowed with an extensive atmosphere, each fragment would obviously carry off a portion of atmosphere proportioned to its magnitude; but two of the fragments, Juno and Vesta, have no atmosphere at all, consequently the atmospheres of Ceres and Pallas could not have been derived from the original planet, but must have been communicated to them at a period posterior to the divergency of the fragments.' We leave the reader to form his own judgment of this curious hypothesis; certainly the facts on which this writer reasons are themselves most extraordinary.

It appears that twenty-four comets have passed between the Sun and the orbit of Mercury; thirty-three between the orbits of Mercury and Venus; twenty-one between the orbits of Venus and the Earth; sixteen between the orbits of the Earth and Mars; three between the orbits of Mars and Ceres; and one between the orbits of Ceres and Jupiter: that thirty-two Comets have appeared between the months of April and September, and sixty-six between September and April: that the greater part of the comets have their perihelion nearest to their ascending nodes: that fifty of the comets move from west to east and not in the opposite direction: and that the orbits of the comets are not confined to any particular region of the heavens, like the old planets, but seem to be inclined at every possible angle of the ecliptic.

COMETEAU, or COMMOTAU, a town of Bohemia in the circle of Saatz, with a handsome town-house. It was taken by Zisca, in 1421, and all the inhabitants, men, women, and children, were put to the sword. In 1648 it surrendered to the Swedes at discretion. It is seated in a fertile plain, thirty miles north-west of Prague.

COMETES, in botany, a genus of the monogynia order, and tetrandria class of plants. The involucre is tetracyllous and triflorous: CAL. tetracyllous: CAPS. tricocous. Species one only, a native of Surat.

COMFIT, *n. s.* & *v. a.* } Lat. *bellaria arida*;
 Co'MFITURE, *n. s.* } Dutch *konfit*. It should seem that both are formed by hasty pronunciation from confect. A dry sweetmeat; any kind of fruit or root preserved with sugar, and dried.

From country grass to *confitures* of court,
 Or city's *quelque-choses*, let not report
 My mind transport.

Donne.

The fruit that does so quickly waste,
 Men scarce can see it, much less taste,
 Thou *confitest* in streets to make it last.

Cowley.

By feeding me on beans and pease,
 He crams in nasty crevices,
 And turns to *comfits* by his arts,
 To make me relish for deserts.

Hudibras.

COMFORT, *v. a.* & *n. s.* } Low Lat. *com-*
 Co'MFORTABLE, *adj.* } *forto*. *Salvia com-*
 Co'MFORTABLY, *adv.* } *fortat* *nervos*.—
 Co'MFORTER, *n. s.* } *Schol. Sal.* To
 Co'MFORTLESS, *adj.* } strengthen; to en-

liven; to invigorate; to sooth; to relieve in difficulty by assistance, by support, by consolation. That which mitigates the pressure of calamity, allays sorrow, and diminishes agony by a positive infusion of enjoyment. Comfort is the verbal expression of a thing which, to be understood, must be enjoyed, and it can be enjoyed only in merry England. It is the indigenous plant of our own soil, and cannot be made an exotic. 'Comfort, that genuine English word, describes what England only affords; we may find *pleasure* in every country, but *comfort* is to be found in our own country only; the grand feature in *comfort* is substantiality; in that of *pleasure*, it is warmth. *Pleasure* is quickly succeeded by pain; it is the lot of humanity, that to every *pleasure* there should be an alloy: *comfort* is that portion of pleasure which seems to be exempt from this disadvantage; it is the most durable part of *pleasure*.'—*Crabbe*.

For which, this noble duk, as he we can,
Comforteth and honoureth every man;
 And made revel, all the longe night,
 Unto the strange lords, as was right.

Chaucer's Canterbury Tales.

The evidence of God's own testimony, added unto the natural assent of reason, concerning the certainty of them, doth not a little *comfort* and confirm the same.

Hooper.

Light excelleth in *comforting* the spirits of men: light varied doth the same effect, with more novelty. This is the cause why precious stones *comfort*.

Bacon's Natural History.

He had no brother, which, though it be *comfortable* for kings to have, yet draweth the subjects eyes aside.

Shakspeare. Henry VII.

The heavens have blest you with a goodly son,
 To be a *comforter* when he is gone. *Id.* *Richard III.*

Your children were vexation to your youth,
 But mine shall be a *comfort* to your age. *Id.*

My lord leans wond'rously to discontent;
 His *comfortable* temper has forsook him;
 He is much out of health. *Id.* *Timon.*

I will keep her ignorant of her good,
 To make her heavenly *comforts* of despair,
 When it is least expected.

Id. *Measure for Measure.*

Her soul heaven's queen, whose name she bears,
In *comfort* of her mother's fears,
Hath placed among her virgin train. *Ben Jonson.*

Use need not fear

To pass commodiously this life, sustained
By him with many *comforts*, till we end
In dust, our final rest and native home. *Milton.*

On thy feet thou stood'st at last,

Though *comfortless*, as when a father mourns
His children, all in view destroyed at once. *Id.*

That unsociable *comfortless* deafness had not quite
tired me. *Swift.*

Be *comforted*, relief is near,
For all our friends are in the rear. *Gay.*

Upon view of the sincerity of that performance,
hope *comfortably* and cheerfully for God's performance.
Hammond.

As they have no apprehension of those things, so
they need no *comfort* against them. *Tillotson.*

O false ambition!

Thou lying phantom! whither hast thou lur'd me!
Even to this giddy height; where now I stand
Forsaken, *comfortless*, with not a friend
In whom my soul can trust. *Broten's Barbarossa.*

Fancy from *comfort* wanders still astray;

Ah, Melancholy! how I feel thy power!
Long have I laboured to elude thy sway;
But 'tis enough, for I resist no more. *Beattie.*

Yet lingering *comfortless* in lonesome wild,
Were Echo sleeps 'mid cavern'd vales profound,
The pride of Troy, Dominion's daily child,
Pines while the slow hour stalks its sullen round. *Id.*

For if my desultory strain, with ruth
And indignation, make thine eyes o'erflow,
Alas! what *comfort* could thy anguish soothe,
Shouldst thou the extent of human folly know. *Id.*

COMFORTER, *n. s.* The third person of the
Holy Trinity; the paraclete, paraclete.

They were filled with the Holy Ghost, with spiritual
comfort, spiritual joy and exultation. Instead of
fearing and flying from their enemies, as before at
the apprehension and crucifixion of their Master, they
now boldly faced them, prepared to stand before rulers
to speak of God's testimonies, even 'before kings,
without being ashamed.' They were no longer
grieved or offended at the thought of suffering for the
truth; they rejoiced in tribulation of that sort, and
conceived themselves to have acquired a new dignity,
when 'counted worthy so to suffer.' Such was the
mighty change wrought in their minds, through the
power of 'the Holy Ghost, the Comforter.'

Bishop Horne's Sermons.

COMFORT, POINT, is the most south part of Elizabeth-city county, in Virginia, formed by James River, at its mouth in Chesapeake Bay. It lies nineteen miles west by north of Cape Henry.

COMFREY, *n. s.* Lat. *consolida*; Fr. *com-frie*, a plant.

COMICK, *adj.* } Lat. *comicus*; Fr. }
COMICAL, *adj.* } *comique*. Relating to }
COMICALLY, *adv.* } comedy, as distinguish- }
COMICALNESS, *n. s.* } ed from tragedy.— }
Mirthful, merry, diverting.

Stately triumphs, mirthful *comick* shows,
Such as befit the pleasure. *Shakspeare. Henry VI.*

I never yet the tragick muse essayed,
Deterred by thy inimitable maid;
And when I venture at the *comick* stile,
Thy scornful lady seems to mock my toil.

Waller.

A *comick* subject loves an humble verse
Thyestes scorns a low and *comick* stile;
Yet comedy sometimes may raise her voice.

Roscommon.

Thy tragick muse gives smiles, thy *comick* sleep.
Dryden.

The greatest resemblance of our author is in the
familiar stile and pleasing way of relating *comical* ad-
ventures of that nature. *Id. Fables. Preface.*

Something so *comical* in the voice and gestures,
that a man can hardly forbear being pleased.

Addison on Italy.

That all might appear to be knit up in a *comical*
conclusion, the duke's daughter was afterwards joined
in marriage to the lord Lisle. *Hayward.*

They deny it to be tragical, because its catastrophe
is a wedding, which hath ever been accounted *comical*.
Gay.

For the dame, by her skill in affairs astronomical,
Imagined to live in the clouds was but *comical*. *Id.*

COMINES, a town of France, in the depart-
ment of the North, and ci-devant province of
French Flanders, situated on the river Lis, which
divides it into two parts. It has been much re-
duced since the period in which it gave birth to
the celebrated author below; but has still a po-
pulation of about 2000. It is five miles south-
west of Menin, seven north of Lisle, and
twenty-five south of Bruges.

COMINES (Philp De), an historian, born in
Flanders in 1446; and, although of noble de-
scend, his education was very limited. He lived
first at the court of Charles the Bold, duke of
Burgundy, where he stayed about eight years;
when Louis XI. invited him to France; where
he was highly promoted, and executed several
successful negociations. But on the death of
Louis he was thrown into prison by Charles
VIII.; but on being brought before the parlia-
ment of Paris he was released. Comines was
a man of more natural abilities than learning;
he spoke several living languages, but knew
nothing of the dead. He has left behind him
Memoirs of his own Times that are admired.
It was a saying of Catherine de Medicis, that
Comines made as many heretics in politics, as
Luther had done in religion.

COMINGES, a ci-devant territory of France,
the east division of the late province of Gas-
cony; about fifteen leagues in length, and six
in breadth, which is now included in the depart-
ment of Gers. It is the see of a bishop, whose
residence was at St. Bertrand, the capital.

COMITATUS, in law, a county. Ingulphus
tells us, that England was first divided into
counties by king Alfred; and the counties into
hundreds, and these again into tythings; and
Fortescue says, that regnum Angliæ per comi-
tatus, ut regnum Franciæ per bullivatus distin-
guitur. Sometimes it is taken for a territory or
jurisdiction of a particular place; as in Mat.
Paris, A.D. 1234. See COUNTY.

COMITIA, in Roman antiquity, general as-
semblies of the people, called by a magistrate
for the enjoyment or prohibition of anything
by their votes. They were of three sorts; cu-
riata, centuriata, and tributa; from the three
grand divisions of the city and people into
curiæ, centuriæ, and tribes.

COMITIA CALATA, from *καλεω*, to call, was in early times a common epithet for all the comitia, though it was at last restrained to two sorts of assemblies; those for the creation of priests, and those for the regulation of last wills and testaments.

COMITIA CENTURIATA were instituted by Servius Tullius; who, obliging every one to give a true account of what he was worth, according to those accounts divided the people into six classes, which he subdivided into 193 centuries. The first class, containing the equites and richest citizens, consisted of ninety-eight centuries. The second, taking in the tradesmen and mechanics, consisted of twenty-two centuries; the third of twenty; the fourth of twenty-two; and the fifth of thirty: the sixth, being filled up with the poorer sort, made but one century; and was seldom regarded, or allowed any power in public matters. Hence it is common with the Roman authors, when they speak of the classes, to reckon no more than five, the sixth not being thought worth their notice. This last class was divided into two parts, or orders; the *proletarii* and the *capite censi*. The former, as their name implies, were merely designed to stock the republic with men, as they could supply it with little money; and the latter, who paid the lowest tax of all, were marshalled by their heads. Persons of the first rank, from their pre-eminence, had the name of *classici*; whence the term *classic*. All others were said to be *infra classem*. The assembly of the people by centuries was held for the electing of consuls, censors, and prætors; for the judging of persons accused of what they called *crimen per duellionis*, or actions by which the party had showed himself an enemy to the state, and for the confirmation of all such laws as were proposed by the chief magistrates. The place appointed for their meeting was the *Campus Martius*; because in the primitive times the people, to prevent any sudden assault from their enemies, went armed to these assemblies. But it was afterwards thought sufficient to place a body of soldiers as a guard in the *janiculum*, where an imperial standard was erected, the taking down of which denoted the conclusion of the comitia. By the institution of these comitia, Servius Tullius took the whole power from the commons: for the centuries of the first and richest class being called out first, who were three more in number than all the rest put together, if they all agreed, as they generally did, the business was decided, and the votes of the other classes were needless. Accordingly the three last scarcely ever came to vote. The commons, in the time of the republic, to remedy this disadvantage, obtained, that, before they proceeded to voting at these comitia, that century should give their suffrages first upon whom it fell by lot, with the name of *centuria prerogativa*; the rest being to follow according to the order of their classes. The prerogative century being chosen by lot, the chief magistrates, sitting in a tent in the middle of the *Campus Martius*, ordered that century to come out and give their voices; upon which they separated from the rest, and came into an enclosed apartment, which they termed *septa*, or *ovilia*, passing over the

pontes, or narrow boards, laid for the occasion; on which account, *de ponte dejecti* signifies to be denied the privilege of voting, and persons thus dealt with were called *depontani*. At the hither end of the *pontes* stood the *diribitores*, a sort of under officers, so called from their marshalling the people, and delivered to every man, in the election of magistrates, as many tables as there appeared candidates, one of whose names was written upon every tablet. A proper number of chests were set ready in the *septa*, and every body threw in which tablet he pleased. By the chests were placed some of the public servants, who taking out the tablets of every century, for every tablet, made a point in another tablet which they kept by them. Thus, the business being decided by most points, gave occasion to the phrase *omne tulit punctum*. The same method was observed in the judiciary process at these comitia, and in the confirmation of laws; except that, in both these cases, only two tablets were offered to every person, one marked a and the other u. r. See A. But though in the election of magistrates, and in the ratification of laws, the votes of that century, whose tablets were equally divided, signified nothing; yet in trials of life and death, if the tablets *pro* and *con* were the same in number, the person was acquitted.

COMITIA CURIATA owed their origin to the division which Romulus made of the people into thirty *curiæ*; ten being contained in every tribe. They answered in most respects to our parishes, being not only separated by proper bounds and limits, but distinguished by their different places for public worship, which was performed by priests called *curiones*. The power of calling these assemblies belonged at first only to the kings; but upon the establishment of the democracy, the same privilege was allowed to most of the chief magistrates, and sometimes to the pontifices. The persons who voted, were such Roman citizens as belonged to the *curiæ*: or lived in the city, and conformed to the rites of their *curiæ*; all those being excluded who dwell without the bounds of the city, retaining the ceremonies of their own country, though they had been admitted free citizens of Rome. These, and the other comitia, were held only as business required. The people being met together, and confirmed by the report of good omens from the augurs, the *rogatio*, or business to be proposed, was publicly read; after which the people divided into their proper *curiæ*, and consulted of the matter; and then the *curiæ* being called out, by lot, gave their votes man by man, in ancient times *vivâ voce*, and afterwards by tablets; the most votes in every *curiæ* going for the voice of the whole *curiæ*, and the majority of the *curiæ* for the general consent of the people. In the time of Cicero, the comitia curiata were so neglected, that they were formed only by fifty *hætores* representing the thirty *curiæ*; whence, in his second oration against Rullus, he calls them *comitia adumbrata*.

COMITIA TRIBUTA. The division of the people into tribes was an invention of Romulus, after he had admitted the Sabines into Rome; and though he constituted at that time only three,

yet as the state increased in power, and the city in number, they rose by degrees to thirty-five. For a long time after this institution, a tribe signified only a space of ground with its inhabitants. But at last it was considered as no longer *pars urbis*, but *pars civitatis*; not a quarter of the city, but a company of citizens living where they pleased. This change was chiefly occasioned by the original difference between the tribes in point of honor. For Romulus having committed all mechanic arts to the care of strangers, slaves, and libertines; and reserved the labor of agriculture to the freemen and citizens, who by this active course of life might be prepared for martial service; the *tribus rustice* were for this reason esteemed more honorable than the *tribus urbanae*. And all persons being desirous of getting into the more creditable division, by adoption, by the power of censors, or the like, that rustic tribe which had the most worthy names in its roll, had the preference to all others, though of the same general denomination. Hence all of the same great family, bringing themselves by degrees into the same tribe, gave the name of their family to the tribe they honored; whereas at first the generality of the tribes did not borrow their names from persons but from places. The first assembly of the tribes we meet with, was about A. U. C. 263, convened by Sp. Sicinius, tribune of the commons, upon the trial of Coriolanus. Soon after, the tribunes of the commons were ordered to be elected here; and at last, all the inferior magistrates, and the collegiate priests. The same *comitia* served for the enacting of laws relating to war and peace, and all others proposed by the tribunes and plebeian officers. They were generally convened by the tribunes of the commons; but the same privilege was allowed to all the chief magistrates. They were confined to no place; and therefore sometimes held in the *comitium*, or the capitol. This last sort of the *comitia* only could be held without the consent and approbation of the senate, which was necessary to the convening of the other two.

COMITIAL, *adj.* Lat. *comitia*. An assembly of the Romans. Relating to the assemblies of the people of Rome.

COMITIALIS MORBUS, an appellation given to the epilepsy, as the *comitia* of ancient Rome were dissolved, if any person in the assembly happened to be taken with this distemper.

COMITIUM, in Roman antiquity, a large hall in the forum, which occupied the entire space between the Palatine Hill, the Capitol, and the Via Sacra. It was separated originally from the forum by rows of steps and barriers; and was uncovered till the memorable year that Hannibal first entered Italy, when it was embellished and covered with a roof, supported by lofty and beautiful fluted columns of the Corinthian order. Three of them, with their architrave, are still standing in the ancient forum, near the church of Santa Maria Liberatrice. The capitals are wrought and finished on the side next the forum, but rough on the opposite side. In this hall the *comitia* were usually held.

COMITY, *n. s.* Lat. *comitas*. Courtesy; civility; good breeding.

CO'MMA, *n. s.* *Κόμμα*. The point which notes the distinction of clauses, and order of construction, in the sentence; marked thus (,).

Commas and points they set exactly right. *Pope.*

COMMA, among grammarians, is differently used and defined by different authors. According to F. Bussier, the comma serves to distinguish those members of a period, in each of which is a verb and a nominative; thus, That so many people are pleased with trifles, is owing to a weakness of mind, which makes them love things easy to be comprehended. Besides this, the comma is used to distinguish, in the same member of a period, several nouns substantive, or nouns adjective, or verbs not united by a conjunction; thus, Virtue, wit, knowledge, are the chief advantages of a man. If the words are united in the same phrase with a conjunction, the comma is omitted; thus, the imagination and the judgment do not always agree. The ingenious author of the tract, *De Ratione Interpungendi*, printed with Vossius's *Element. Rhetor.* Lond. 1724, lays down the use of a comma to be, to distinguish the simple members of a period or sentence; i. e. such as only consist of one subject, and one definite verb. But this rule does not hold throughout; the same author instancing many particular cases not yet included herein, where yet the comma is advisable. See **PUNCTUATION**. It is a general rule that a comma ought not to come between a nominative and a verb, or an adjective and substantive, when these are not otherwise disjoined: thus, in the sentence, God ruleth with infinite wisdom, a comma between God and ruleth, or between infinite and wisdom, would be absurd. But to this exceptions may occur; as when not a single word, but a sentence, is the nominative; thus, in the above example, where the sentence, that so many people are pleased with trifles, forms the nominative to the verb is, a comma at trifles is proper, both for the sake of perspicuity, and as coinciding with a slight natural pause.

COMMA, in music. See **INTERVAL**.

COMMA'ND, *v. a. v. n. & n. s.* Lat. *mando*;

COMMA'NDER, *n. s.* } Fr. *command-*

COMMA'NDMENT, *n. s.* } *er.* To exer-

COMMA'NDRESS, *n. s.* } cise the chief authority; to issue mandates; to superintend; to govern: correlative to obey; and contrary to prohibit. The substantives are cognate with the verb, and but echo its various significations, with the exception of commander, which is used technically. A paving beetle, or a very great wooden mallet, with a handle about three feet long, to use in both hands: and likewise an instrument of surgery.

The preest him besith all that ever he can
To don as this Charon, this cursed man,
Commandeth him; and faste bleweth the fire
For to come to the effect of his desire.

Chaucer's Canterbury Tales.

After avarice cometh glotonie, which is expresse
ayenst the *commandement* of God.

Id. The Persones Tale.

The glossocomium, commonly called the *commander*, is of use in the most strong tough bodies, and where the laxation hath been of long continuance.

Wiseman's Surgery.

Fairie Queene of Love! my life thou maist *command*,
Too slender price for all thy former grace,
Which I receive at thy so bounteous hand;
But never dare I speak her name or face. *Spenser.*

Thence she *commanded* me to prison new;
Whereof I glad did not gainesay nor strive,
But suffered that same dwarfe me to her doungeon drive.
Id.

We'll do thee homage, and be ruled by thee;
Love thee as our *commander* and our king. *Shakespeare.*

I thought that all things had been savage here,
And therefore put I on the countenance
Of stern *commandment*. *Id. As you like it.*

Commanded always by the greater gust;
Such is the lightness of you common men.
Id. Henry VI.

Up to the Eastern tower,
Whose height *commands* as subject all the vale,
To see the sight. *Id. Troilus and Cressida.*

Take pity of your town and of your people,
While yet my soldiers are in my *command*.
Id. Henry V.

They plainly require some special *commandment* for
that which is exacted at their hands. *Hooker.*

To prescribe the order of doing in all things, is a
peculiar prerogative, which wisdom hath, as queen of
sovereign *commandress*, over all other virtues. *Id.*

The Romans, when *commanders* in war, spake to
their army, and styled them, My soldiers.
Bacon's Apophthegms.

Whatever hypocrites austereIy talk
Of purity, and place, and innocence,
Defaming as impure what God declares
Pure, and *commands* to some, leaves free to all.
Our Maker bids increase: who bids abstain
But our destroyr, foe to God and man? *Milton.*

His eye might there *command* wherever stood
City, of old or modern fame, the seat
Of mightiest empire. *Id.*

Of this tree we may not taste nor touch;
God so *commanded*, and left that *command*
Sole daughter of his voice. *Id. Paradise Lost.*

As there is no prohibition of it, so no *command* for
it. *Taylor.*

Sir Frederick and Sir Solomon draw lots
For the *command* of politicks and Scots:
Hence fell to words, but quarrels to adjourn,
Their friends agreed they should *command* by turn.
Marvell.

Those two *commanding* powers of the soul, the un-
derstanding and the will. *South.*

The steepy stand,
Which overlooks the vale with wide *command*.
Dryden's Æneid.

Be you *commandress* therefore, princess, queen
Of all our forces, be thy word a law. *Fairfax.*

Command and force may often create, but can never
cure, an aversion; and whatever any one is brought
to by compulsion, he will leave as soon as he can.
Locke on Education.

Should he, who was thy lord, *command* thee now
With a harsh voice, and supercilious brow,
To servile duties. *Dryden's Pers. Sat. 5.*

Charles, Henry, and Francis of France, often ad-
ventured rather as soldiers than as *commanders*.
Hayward.

One side *commands* a view of the finest garden in
the world. *Addison's Guardian.*

As seemed to speak him born for high *command*;
Though now, for many a moon, the sport of Fate,
A willing exile from his native land. *Gay.*

COMMAN'DERY, *n. s.* From *command*.
A body of the knights of Malta, belonging to the
same nation.

COMMAN'DERY, or COMMANDRY, a kind of be-
nefice belonging to a military order, and con-
ferred on ancient knights who had done service
to the order. There are regular commanderies,
obtained by merit: there are others of favor,
conferred by the grand master: there are also
commanderies for the religious, in the orders of
St. Bernard and St. Anthony. The commanderies
of Malta are of different kinds; for knights,
chaplains, and brothers servitor. The knight to
whom one of these is given is called *commander*;
which agrees nearly with the *prepositus* set over
the monks in places at a distance from the mo-
nasters. Thus, the simple commanders of Malta,
are rather farmers of the order than beneficiaries,
paying a certain tribute, called *responsio*, to the
common treasure of the order.

COMMANDINE, or COMMANDINUS (Fred-
eric), born at Urbino in Italy, in the sixteenth
century, and descended from a noble family. To great
skill in mathematics he added a profound know-
ledge of the Greek Tongue. He translated several
of the Greek mathematicians into Latin, as
Archimedes, Apollonius, Euclid, &c. which no
writer till then had attempted.

COMMANOES, one of the small Virgin Isles,
in the West Indies, situated to the N. N. E. of
Tortula. Long. 63° 0' W., lat. 18° 25' N.

COMMANAWANA, a bay on the north
coast of the island of St. Vincent, about a mile
east of Tarrata Point.

COMMATERIAI, *adj.* } Lat. *con* and *ma-*
COMMATERIA'LITY, *n. s.* } *teria*. Resembling
another thing, or consisting of the same matter.

The beaks in birds are *commaterial* with teeth.

Bacon.

The body adjacent and ambient is not *commaterial*,
but merely heterogeneal towards the body to be pre-
served. *Id.*

COMMELIN (John), a celebrated Dutch bo-
tanist, was born at Amsterdam in 1629. He, as
well as his father, was a magistrate of that city,
where he formed a well-managed botanical gar-
den, and died in 1692. His works are, 1. Cata-
logus Plantarum Indigenarum Hollandiæ,
12mo. 2. Catalogus Plantarum, Horti Medici
Amstel. Besides which he assisted in the Hortus
Indicus Malabaricus.

COMMELIN (Gaspar), physician and nephew of
the above, was appointed professor in botany and
director of the garden at Amsterdam. He pub-
lished, 1. Flora Malabarica. 2. Præludia Ana-
tomica, 4to. 3. Præludia Botanica. 4. Icones
Plantarum, præsertim ex Indiis collectarum. 5.
Botanographia Malabarica, folio.

COMMELINA, in botany, a genus of the
monogynia order and triandria class of plants;
natural order sixth, ensate: cor. hexapetalous;
nectaria three, of a cruciform figure, and inserted
into their proper filaments. Species thirteen, all
natives of warm climates. They are herbaceous
plants, rising from two to four feet high, and
adorned with blue or yellow flowers. Their
culture is the same with that of the common
exotics.

COMMEMORATE, *v. a.* } Lat. *con* and
 COMMEMORABLE, *adj.* } *memoro*. To pre-
 COMMEMORATION, *n. s.* } serve in memory
 COMMEMORATIVE, *adj.* } that which is worthy
 to be mentioned with honor, by some public
 act or solemnity, which is the commemoration;
 and whatever tends to preserve the recollection
 is commemorative.

That which is daily offered in the church, is a daily
commemoration of that one sacrifice offered on the cross.

Taylor.

St. Austin believed that the martyrs, when the *com-
 memorations* were made at their own sepulchres, did
 join their prayers with the churches, in behalf of those
 who there put up their supplications to God.

Stillingfleet.

Such is the divine mercy which we now *commemo-
 rate*; and, if we *commemorate* it, we shall rejoice in
 the Lord.

Fiddes.

The annual offering of the Paschal lamb was *commemo-
 rative* of that first Paschal lamb.

Atterbury.

The original use of sacrifice was *commemorative* of
 the original revelation; a sort of daily memorial or
 record of what God declared, and man believed.

Forbes.

But who was she, the lady of the dead,
 Tombed in a palace? was she chaste and fair?
 Worthy a king's—or more—a Roman's bed?
 What race of chiefs and heroes did she bear?
 What daughter of her beauties was the heir?
 How lived—how loved—how died she? Was she not
 So honoured—and conspicuously there,
 Where meaner relics must not dare to rot,
 Placed to *commemorate* a more than mortal lot.

Byron's Child of Harold.

COMMENA (Anna), daughter of Alexius
 Comnenus, emperor of the East; a most accom-
 plished princess, equally eminent for learning
 and virtue. She flourished about the beginning
 of the twelfth century, and wrote The Alexiad, a
 history of the life and actions of her father,
 which is highly esteemed. It is in fifteen books,
 of which the first eight were published by Hes-
 chelius in 1610, and afterwards the whole fifteen
 were printed in the collection of the Byzantine
 historians; with a diffuse and incorrect Latin
 version by the jesuit Possinus, in 1651; but with
 excellent notes by the learned Du Fresne, in
 1670.

COMMENCE, *v. n. & v. a.* } Fr. *commencer*.

COMMENCEMENT, *n. s.* } To begin; to
 take date from, as from the beginning; to make
 a beginning, as to commence a suit.

Most shallowly did you these arms *commence*,
 Fondly brought here, and foolishly sent hence.

Shakspeare.

Man, conscious of his immortality, cannot be with-
 out concern for that state that is to *commence* after this
 life.

Rogers.

If wit so much from ignorance undergo,
 Ah! let not learning too *commence* its foe!

Pope.

The waters were gathered together into one place,
 the third day from the *commencement* of the creation.

Woodward's Natural History.

But if it is probable that the first men might see
 the *commencement* of those species of animals, whose
 formation required longer time than their own, it is
 not impossible, neither, that they might see the *com-
 mencement* of those species, whose formation required
 less time.

Bolinobroke.

COMMEND, *v. a. & n. s.* } Lat. *commendo*.
 COMMENDABLE, *adj.* } compounded of
 COMMENDABLY, *adv.* } *com* and *mendo*;
 COMMENDATION, *n. s.* } to commit to the
 COMMENDATORY, *adj.* } good opinion of
 COMMENDER, *n. s.* } others, and some-

times to their care; to represent as worthy of
 regard or kindness; to suggest to the memory;
 to praise, yet praise may be given either by
 equals or inferiors; but commendation is the
 part of a superior; it is praise coming from one
 above us, as a parent commends his child for an
 act of charity.

Father, into thy hands I *commend* my spirit. *Luke.*

And I it hold vertuose and right *commendabil*,

To have very knowlech of things reprovabil.

Chaucer's Canterbury Tales.

Certes, the *commendation* of the peple is ful false,
 and brotel for to trust; this day they praise, to-morwe
 they blame. Got wote, desire to have *commendation*
 of the peple hath caused deth to many a besy man.

Id.

The charge, which God doth unto me direct,
 Of his deare safety, I to thee *commend*;

Yet will I not forgoe, ne yet forget
 The care thereof, myselfe, unto the end,
 But evermore him succour and defend
 Against his foe and mine.

Spenser.

His fame would not get so sweet and noble an air
 to fly in as in your breath, so could not you find a
 fitter subject of *commendation*.

Sidney.

It doth much add to a man's reputation, and is like
 perpetual letters *commendatory*, to have good forms;
 to attain them, it almost sufficeth not to despise them.

Bacon's Essays.

Who is Silvia? What is she,
 That all our swains *commend* her?
 Holy, fair, and wise is she.

Shakspeare.

Signior Anthonia
Commends him to you.—

—Ere I ope his letter,
 I pray you tell me how my good friend doth.

Id. Merchant of Venice.

Tell her I send to her my kind *commends*:
 Take special care my greetings be delivered.

Id. Richard II.

Hark you Margaret,
 No princely *commendations* to my king!—

—Such *commendations* as become a maid,
 A virgin, and his servant say to him.

Id. Henry VI.

The choice of them should be by the *commendation*
 of the great officers of the kingdom.

Bacon.

Order and decent ceremonies in the church, are
 not only comely, but *commendable*.

Id. Advice to Villiers.

Old men do most exceed in this point of folly,
commending the days of their youth they scarce remem-
 bered, at least well understood not.

Broune's Vulgar Errors.

Among the objects of knowledge, two especially
commend themselves to our contemplation; the know-
 ledge of God, and the knowledge of ourselves.

Hale's Origin of Mankind

She guiltless damsel, fying the mad pursuit
 Of her enraged step dame Guendolez,
Commended her fair innocence to the Lord
 That staid her flight, with his cross-flowing course.

Milton

Some say, (and many men doe these *commend*),
 That all our deeds, and fortunes doe depend
 Upon the motions of celestiall spheres;
 And on the constellations of the starres.

George Withers

Of preachers the shire beholdeth a number, all commendably labouring in their vocation.

Carew's Survey of Cornwall.

Good-nature is the most godlike commendation of a man.

Dryden's Juvenal. Dedication.

Each finding, like a friend.

Something to blame, and something to commend.

Pope.

Whene'er I hear a knave commend,

He bids me shun his worthy friend.

What praise! what mighty commendation!

But 'twas a fox who spoke the' oration

Foxes this government may prize

As gentle, plentiful and wise.

Gay.

Such as a concurrence of two extremes, by most of the same commendators and disprovers.

Wotton.

COMMENDAM, low Lat. *commenda.*

Commendam is a benefice, which, being void, is commended to the charge and care of some sufficient clerk, to be supplied until it be conveniently provided of a pastor.

Cowell.

It had been once mentioned to him, that his peace should be made, if he would resign his bishoprick, and deanery of Westminster; for he had that in commendam.

Clarendon.

COMMENDAM, in the ecclesiastical law, signifies also the administration of the revenue of a benefice, given to a layman, to hold by way of depositum for six months, in order to repairs, &c. Anciently the administration of vacant bishoprics belonged to the nearest neighbouring bishop; thence called commendatory. This custom appears to be very ancient. St. Athanasius says of himself, according to Nicephorus, that there had been given him in commendam, another church besides that of Alexandria, whereof he was stated bishop. When a priest is made bishop his parsonage becomes vacant; but, if the king give him power, he may hold it in commendam. A commendam recipere is to take a benefice de novo in the bishop's own gift, or in the gift of some other patron with his consent.

COMMENDATARY, *n. s.* from commendam. One who holds a living in commendam.

COMMENSALITY, *n. s.* from Lat. *commensalis.* Fellowship of table; the custom of eating together.

They being enjoined and prohibited certain foods, thereby to avoid community with the Gentiles, upon promiscuous commensality.

Browne's Vulgar Errors.

COMMENDATUS, one who lives under the protection of a great man. *Commendatii* homines were persons who, by voluntary homage, put themselves under the protection of any superior lord; for ancient homage was either predial, due for some tenure; or personal, which was by compulsion, as a sign of necessary subjection; or voluntary, with a desire of protection. These last were sometimes called *hominies ejus commendati*, as often occurs in Doomsday book. *Commendati dimidii* were those who depended on two several lords, and paid one-half of their homage to each; and sub-commendati were like sub-tenants under the command of persons who were themselves under the command of some superior lord. There were also *dimidii sub commendati*, who bore a double relation to such depending lords.

COMMENSURATE, *v. a. & adj.* } Latin
 COMMENSURATELY, *adv.* } *commen-*
 COMMENSURABLE, *adj.* } *sus,* or
 COMMENSURABILITY, *n. s.* } *commeti-*
 COMMENSURABLENESS, *n. s.* } *or,* mea-
 COMMENSURATION, *n. s.* } *suring*

in accordance with some other thing, being suitable in measure to something else; that is commensurate which is made to rise to the same measure or degree. Dr. Johnson explains commensurability as the capacity of being compared with another, as to the measure; or of being measured by another. Thus an inch and a yard are commensurable, a yard containing a certain number of inches; the diameter and circumference of a circle are incommensurable, not being reducible to any common measure: proportion.

A body over great, or over small, will not be thrown so far as a body of a middle size; so that, it seemeth, there must be a commensuration or proportion between the body moved and the force, to make it move well.

Bacon's Natural History.

There is no commensurableness between this object and a created understanding, yet there is a congruity and connaturality.

Hale's Origin of Mankind.

Some place the essence thereof in the proportion of parts, conceiving it to consist in a comely commensurability of the whole unto the parts, and the parts between themselves.

Browne.

That division is not natural, but artificial, and by agreement, as the aptest terms to commensurate the longitude of places.

Id. Vulgar Errors.

They permitted no intelligence between them, other than by the mediation of some organ equally commensurate to soul and body.

Government of the Tongue.

All fitness lies in a particular commensuration, or proportion, of one thing to another.

South.

We are constrained to make the day serve to measure the year as well as we can, though not commensurately with each other; but by collecting the fraction of days in several years, till they amount to an even day.

Holder on Time.

Matter and gravity are always commensurate.

Bentley.

Is our knowledge adequately commensurate with the nature of things.

Glanville's Scepasis.

Those who are persuaded that they shall continue for ever, cannot chase but aspire after a happiness commensurate to their duration.

Tillotson.

COMMENSURABLE IN POWER, is said of right lines, when the squares are measured by the same square or superficies.

COMMENSURABLE NUMBERS, whether integers or fractions, are such as can be measured or divided by some other number without any remainder; such are 12 and 18 as being measured by 6 and 3.

COMMENSURABLE SURDS, those that, being reduced to their last terms, become true figurative quantities of their kind; and are therefore as a rational quantity to a rational one.

COMMENT, *v. n. & n. s.* } Lat. *commen-*

COMMENTARY, *n. s.* } *tion,* from *com-*

COMMENTATOR, *n. s.* } *miniscor,* to call

COMMENTER, *n. s.* } to mind; does

not necessarily imply what is written; but commentary is never used of what is spoken. Commentary, says Crabbe, is a species of remark which often loses in good nature what it gives us

seriousness; it is mostly applied to particular persons or cases, and more commonly employed as a vehicle of censure than of commendation. This term, when not employed in personal cases, serves for explanation only. Commentaries are minute and elaborate expositions of the text of any author; but more especially applied to the sacred writings. It is sometimes used in the same sense with memoir, in the modern affectation reminiscences, which serves so many coxcombs as the vehicle of self-gratulation and disgusting vanity.

In such a time as this, it is not meet
That every nice offence should bear its *comment*.

Shakespeare.

Enter his chamber, view his lifeless corpse,
And *comment* then upon his sudden death.

Id. Henry IV.

Forgive the *comment* that my passion made
Upon thy feature; for my rage was blind.

Id. King John.

Were, in a private *commentary* which he wrote of
that service, testified that eight hundred were slain.

Bacon.

A company of stern readers dislike the second of
the *Aeneads*, and Virgil's gravity, for inserting such
amorous passions in an heroic subject; but Servius,
his *commentator*, justly vindicates the poet's worth,
wisdom, and discretion, in doing as he did.

Burton's Anat. Mel.

Silly as any *commentator* goes by
Hard words or sense.

Donne.

Such are thy secrets, which my life makes good,
And *comments* on thee; for in every thing
Thy words do find me out, and parallels bring,
And in another make me understand.

Herbert.

All that is behind will be by way of *comment* on
that part of the church of England's charity.

Hammond's Fundamentals.

In religion, Scripture is the best rule; and the
church's universal practice, the best *commentary*.

King Charles.

All this without a gloss or *comment*,
He could unriddle in a moment,
In proper terms, such as men smatter
When they throw out and miss the matter.

Hudibras.

Adam came into the world a philosopher, which
appeared by his writing the nature of things upon
their names; he could view essences in themselves,
and read forms without the *comment* of their respec-
tive properties.

South's Sermons.

Criticks having first taken a liking to one of these
poets, proceeded to *comment* on him, and illustrate
him.

Dryden's Juvenal. Dedication.

I have made such expositions of my authors, as no
commentator will forgive me.

Dryden.

All the volumes of philosophy,
With all their *comments*, never could invent
So politick an instrument.

Prior

Still, with itself compared, his text peruse;
And let your *comment* be the Mantuan muse.

No *commentator* can more silly pass
O'er a learned unintelligible place.

Id.

They shew still the ruins of Caesar's wall, that
reached eighteen miles in length, as he has declared
it in the first book of his *commentaries*.

Addison on Italy.

Galen's *commentator* tells us, that bitter substances
engender cholera, and burn the blood.

Arbuthnot on Aliments

COMMENTITIOUS, *adj.* Lat. *commenti-
tius*. Invented; fictitious; imaginary.

It is easy to draw a parallelism between that an-
cient and this modern nothing, and make good its re-
semblance to that *commentitious* inanity.

Glanville's Scopsis.

COMMERCE, *n. s. & v. n.* } Lat. *con* and
COMMERCIAL, *adj.* } *merces*. Mer-

chandise; traffic, literally an exchange of com-
modities, and generally interchange or inter-
course. It can subsist only between persons.
'Commerce,' says Crabbe, 'is a species of general
but close intercourse; it may consist either of
frequent meeting and regular co-operation, or in
cohabitation.'

Places of public resort being thus provided, our
repair thither is especially for mutual conference,
and, as it were, *commerce* to be had between God and
us.

Hooker.

How could communities,
Degrees in schools, and brotherhoods in citi
Peaceful *commerce* from dividable shores,
But by degrees stand in authentick place?

Shakespeare. Troilus and Cressida.

Ezekiel, in the description of Tyre, and of the
exceeding trade that it had with the East, as the
only mart town, reciteth both the people with whom
they *commerce*, and also what commodities every
country yieldeth.

Raleigh.

Come, but keep thy wonted state,
With even step and musing gait,
And looks *commerce*ing with the skies,
Thy wrapt soul sitting in thine eyes.

Milton.

When they might not converse or *commerce* with
any civil men; whither should they fly but into
the woods and mountains, and there live in a wild
manner.

Sir J. Davies.

In any country that hath *commerce* with the rest
of the world, it is almost impossible now to be
without the use of silver coin,

Locke.

Instructed ships shall sail to quick *commerce*,
By which remotest regions are allay'd;
Which make one city of the universe,
Where some may gain, and all may be supplied.

Dryden.

These people had not any *commerce* with the other
known parts of the world.

Tillotson.

Now *Commerce*, wealthy goddess, rears her head,
And bids Britannia's fleets their canvass spread.

Gay.

Good-nature, which consists in overlooking of
faults, is to be exercised only in doing ourselves jus-
tice in the ordinary *commerce* and occurrences of life.

Addison.

From the revolution to the death of queen Anne,
however trade and *commerce* might be aided and
encouraged in other respects, they were necessarily
subjected to depredations abroad, and over-loaded by
taxes at home, during the course of two great wars.

Bolingbroke.

I should venture to call politeness benevolence in
trifles, or the preference of others to ourselves, in
little, daily, and hourly occurrences in the *commerce*
of life.

Chatham.

COMMERCE, in the unrestricted sense of the
term, will embrace all the proceedings whereby
an exchange of commodities is effected, whether
by individuals or a nation; and whether for re-
sale or consumption by the purchaser or receiver
of a commodity: while, as a science, it is ob-
viously divisible into its external and internal

branches. Practically, indeed, the word trade has often been used to express the latter. But the history and principles of the entire subject, and its political bearings, have been, until recently, always discussed under the term at the head of this article.

Our views of such a subject in the present paper must be, of course, general: and here the principles of commerce, regarding it only in theory, might seem to require consideration before we enter upon its history. In point of fact, however, the only sound doctrines upon the subject are the fruit of experience. Theories have been continually demolished by the new facts which have been developed in the ever-changing, and, thank heaven, the ever-improving condition of large communities of mankind. In the present age, especially, this science has been, in common with many others, entirely revolutionised and remoulded; in part by the labors of men who have united a knowledge of its practical details with considerable scientific research and original genius, and in part by the peculiar circumstances and extraordinary political revolutions of the last thirty years. Mr. Locke and Dr. Adam Smith led the way, perhaps, to the scientific consideration which the true 'wealth of nations,' has lately received. The late Mr. Ricardo, Mr. Baring, and other practical merchants and traders, have contributed their quota of important information to the incipient system; and we must, on the whole, fully award to the modern science of **POLITICAL ECONOMY** that prominent station that has been claimed for it. It now properly embraces the nature and principles of commercial science; and the reader is referred to that article for every thing that is abstract or systematic in this science. Our present article will be confined to a brief sketch of the history of commerce, generally; the actual state of the commerce of different countries will be treated under their respective names.

There is no doubt but commerce is nearly as ancient as the world itself. It seems, however, pretty evident that the early inhabitants of Arabia were the first who made long voyages. Their country was most happily situated for this purpose; being a peninsula washed on three sides by the famous Arabian, Indian, and Persian seas. That Arabia was very early inhabited is certain; and the first notice we have of any considerable trade refers it to the Ishmaelites, settled in the higher part of that country. To them Joseph was sold by his brethren, when they were going down to Egypt with spicery, balm, and myrrh. Here they appear as inland traders; but the balm and myrrh only were productions of their country. For the spicery they must have had commerce with other nations; and such was this commerce, that, in ancient times, the fame of Arabia for spices led many great authors of antiquity to conclude that spices actually grew there. Indeed there seems little doubt of the extent of this commerce, for in succeeding times Strabo and other authors tell us they were very great traders: they mention particularly what ports they had; the prodigious magazines they kept of the richest kinds of goods; the great wealth they amassed; how magnificently they lived and what extravagant sums of money they

expended in carving, building and statues. It is expressly said they had spices, rich gums, sweet-scented woods, and ivory in abundance. All this not only shows that they had a large and flourishing commerce, but that they traded extensively to the East, for there only were those commodities to be obtained. That the Arabians were the first discoverers of the route to India seems also very probable; they lay nearer and more convenient than any other nation; and, as the situation of their country would naturally incline them to navigation, so with the monsoons they could regularly sail to and from the Indies with great facility. Taking all these things together, there seems good reason to contend that commerce flourished first among the Arabians; and their history exhibits them as, at this early period, both a free and happy people; in consequence.

Egypt is celebrated among the ancient nations for carrying everything to perfection; and it is certain that no pursuit was cultivated there more early, with more assiduity, or with greater success, than commerce. We have seen that the richest commodities were transported thither by land; and it is certain that the most valuable manufactures were invented and perfected in Egypt, long before they were undertaken in other countries: for, as Warburton justly observes, at the time Joseph came into Egypt, the people were not only possessed of all the conveniences of life, but were remarkable for their magnificence, their politeness, and even for their luxury, which argues a long standing traffic. Indeed, the advantages of their country, lying along the Red Sea, and the many benefits arising to them from the Nile, which they emphatically called 'The River,' or 'The River of Egypt,' gave them an opportunity of carrying their inland trade not only to a greater height than any other country then known, but even higher than it has ever been carried by any nation, China excepted; and it has even been thought that the Chinese received, at an early period, some of their institutions and habits from the Egyptians. By such methods, under a wise and well-regulated government, promoting a spirit of industry among the people, the Egyptians became numerous, rich, and powerful; and their country, for large cities, magnificent structures, and continual abundance, the glory and wonder of the old world.

Though the Phœnicians possessed only a narrow slip of the coast of Asia, and were surrounded by powerful and warlike nations, that prevented them from extending themselves on that side, yet they rendered themselves famous by erecting the first naval power that makes any figure in history; in raising which, they availed themselves of all the creeks, harbours, and ports of their territory; and improved them in such a manner that they were no less remarkable for their strength, than for their convenience. Every thing that could contribute to increase their power was attended to; and, while they were admired for their formidable fleets and armies, they were no less so for the advantages they derived from commerce. They were also celebrated by antiquity as the inventors of arithmetic and astro-

romy; and the long voyages they undertook, when no other nation (except the Arabians and Egyptians) could venture farther than their own coasts, shows them to have been considerable proficient in the latter science. It was by these arts that Tyre and Sidon became the most famous marts in the universe; and were the resort both of their neighbours and distant nations, as the storehouses of the world. The two celebrated kings of Israel, David and Solomon, considered their friendship and alliance as of great advantage.

It is not improbable that the latter received from the Phœnicians the first hints of the great advantages that he might derive from the possession of the ports of Elath and Eziongeber, and of the commerce that might from thence be carried on. It is certain that he made use of their assistance in equipping his fleets at these ports; and from thence his vessels, manned chiefly by Phœnicians, sailed to Ophir and Tarsish, bringing into his country various unknown curiosities, and riches in such abundance, that 'He made silver in Jerusalem as stones, and cedar-trees as sycamores that grow in the plains.' If this appear wonderful, let us consider that the return of one voyage only to Ophir produced 450 talents of gold, equal to 51,328 lbs. of our Troy weight, about £2,463,744 sterling, and we cannot doubt of the immense profit arising from this commerce. It also merits notice that the queen of Sheba or Saba, which lies in that part of Arabia before mentioned, having heard, with surprise, the reports that were spread of Solomon's magnificence, made a journey to his court on purpose to satisfy herself; and from the presents she carried with her, 120 talents of gold (£657,650), spices in great abundance, and precious stones, probably the cause of her journey was an opinion that no country was so rich as her own. In confirmation of what is before noticed of the Arabians trading to India, as well as of their having at this time penetrated farther than any others, it is said in this part of Scripture, 'neither were there any such spices as the queen of Sheba gave to king Solomon.' While Solomon reigned he cultivated the arts of peace, kept the wheel of commerce going, and his people employed, thus providing equally for the extension of their happiness and of his own power; while he rendered the land of Israel the glory and wonder of the East. But, under the kings that followed him, the trade of Judea sunk almost as suddenly as it rose; and in a short time they lost those ports on the Red Sea upon which their Indian commerce depended.

The Phœnicians and Egyptians, then became, as it were, heirs of the trade of the world. Egypt monopolised that of the Indies, which, with her corn and manufactures, brought such a great balance of wealth into the country, as enabled her monarchs to accomplish those memorable works, that, in spite of time and the devastations of war, remain the lasting monuments of her power. The Phœnicians drew from Egypt a great part of those rich commodities and manufactures which they exported into all the countries lying between them and the Mediterranean Sea. For the glory and strength of

these governments, as founded on trade, we need only look into the sacred books of Isaiah and Ezekiel, whose accounts are abundantly confirmed by profane history: by comparing these data we behold the industry of the inhabitants of this small country triumphing over all obstacles, and procuring the greatest plenty in a barren soil, and immense riches where, without industry, there must have been the greatest poverty. After the destruction of old Tyre, by Nebuchadnezzar, the spirit of its inhabitants produced a Phœnix, little inferior in beauty to its parent; which soon became mistress of the sea, over which it held supreme dominion till subdued by Alexander the Great.

That this prince's views were far more extended than his conquests, will appear to any one who considers his plan of power; they will behold a greater politician than a conqueror. He framed in his own mind an idea of universal monarchy; and though he was for making use of force to acquire, he very well knew that commerce only could preserve an empire, which was to have no other limits than those which nature had assigned the world. He thought of placing his capital in Arabia; and of disposing things in such a manner, as to have commanded the most distant parts of the Indies, while he maintained a connexion with the most remote countries in Europe. Though he lived scarcely to sketch the outline of his extravagant scheme, the specimen he left in his new city of Alexandria, sufficiently shows how just and how correct his notions were. That city, which it may be said he designed with his own hand, and which was built under his eye, became, in after times, all that he expected, the glory of Egypt, and the centre of commerce.

Tyre, while in her glory as mistress of the sea, founded her noble colony of Carthage, which, whether considered as a capital, a strong fortress, or a commodious port, was admirably situated. On the coast of Africa, equally distant from all the extremities of the Mediterranean, with a fine country behind it, and no power near it capable of restraining its commerce or its growth, its inhabitants rose rapidly to the greatest wealth and power; and their conquests were astonishing: yet these will not bear comparison with their navigation. Westward they stretched as far as Britain; and the Scilly Islands, which are now so inconsiderable, were to them an India, the route to which they carefully concealed. On the other side, they discovered a great part of the African coast, the Canary Islands; and some have thought they even found the way to America. So long as they confined themselves to trade, and the arts connected with it, their power continually increased; but when luxury took the place of industry, and a spirit of ambition banished their old maxims of frugality and labor, their acquisitions ceased, and their destruction soon followed. See CARTHAGE.

In Egypt the Ptolemies, who succeeded Alexander, entered deeply into that monarch's scheme, and they reaped the fruit of his wise establishment. By encouraging trade Ptolemy Philadelphus made his subjects immensely rich, and himself exceedingly powerful. An ancient author

says that he had 120 galleys of war, of a large size, and above 400 other vessels, small and great; which, were it not for the other wonders related of him, would seem incredible. He raised a new city on the coast of the Red Sea; he opened harbours, constructed quays, built inns at proper distances on the roads, and cut a canal from sea to sea. He who comprehended the importance of commerce, so as to dare such expences as these, might have treasures, armies, and fleets, at his pleasure. Under him Alexandria appeared in pomp and splendor; how great this was, we may judge by what we are told was the produce of her customs, which fell little short of two millions of our money annually; and Ptolemy, who understood trade so well, would never cramp it by high duties. If the revenue of the prince from a single port was so great, what must have been the wealth of his subjects?

After Egypt became a Roman province, Alexandria maintained her dignity; and the Romans were struck with the majesty of her appearance. They had hitherto paid little regard to traffic, but they soon comprehended the advantages of such a port and a mart as Alexandria. They confirmed her privileges, protected her inhabitants, and took every possible measure to preserve her commerce; and such was the effect, that she preserved it longer than Rome could preserve her power. She even maintained considerable importance after being made dependent on Constantinople: and under the Arabs recovered no small share of her ancient pre-eminence, as the centre of the trade of the civilised world.

After the Roman empire was overrun by barbarians, and the arts and sciences had nearly perished with that power which cultivated and protected them, commerce was in a manner overwhelmed and lost, and individual merchants either forced by necessity, or led by inclination, took shelter in a few scattered islands lying near the coast of Italy. These would scarcely have been thought to offer a human habitation in time of peace; being divided from each other by narrow channels, so encumbered with shallows, that it was impossible for strangers to navigate them; but here these refugees settled in the sixth century, and finding themselves tolerably safe, they united for improving their condition, and augmenting their security; and became, in the eighth century, a well-settled republic. Such was the rise of the famous and potent state of Venice: her growth was quick, and the increase of her power amazing: she extended her commerce on all sides; and taking advantage of the barbarous maxims of the Mahomedan monarchies, she drew upon herself the profits of the Indian trade, and, in some sense, made Egypt a province, and the Saracens her subjects. While her traffic thus swelled beyond conception, and she became the common mart of all nations, her naval power became also great, and she stretched her conquests not only over Italy, but through the islands of the Archipelago; so as to be at once mistress of the sea, of many fruitful countries, and of part of the great city of Constantinople. But ambition, and the desire of lording it over their neighbours, brought upon them those evils

which produced first a falling off in their commerce, and then of their power.

While commerce raised Venice the Rich on the narrow, marshy, unprofitable, and unwholesome islands in the Adriatic, she erected Genoa the Proud on the inhospitable shores of Liguria; and though surrounded by ambitious and warlike neighbours, in a narrow and unproductive country, and disturbed by perpetual factions and successive revolutions, the trade of Genoa made her rich and great. Her merchants traded to all countries, and acquired wealth by carrying the commodities of the one to the other. Her fleets became formidable, and her conquests important. She subjugated the adjacent island of Corsica, fixed a colony at Caffa, and for some time possessed the coasts on both sides of the Black Sea. The pursuit of commerce beget continual wars between her and Venice; which, though they terminated in leaving the latter mistress of the sea, were fatal to both; but the avarice of the Genoese may be said to have destroyed them, by inducing them to abandon the fair profits of trade for the vile ones of usury.

In another part of the world, about the middle of the thirteenth century, a confederacy of maritime cities was formed, solely regarding commerce, which they extended far and wide. See HANSE TOWNS. When they had become immensely rich and powerful, their behaviour awakened various princes to a more particular view of the dangers that such a league might produce, and the advantages that would naturally flow to their respective states, by recovering their trade, thus in some part made over to others, entirely to themselves. Though from this time the Hanseatic alliance declined, and is now totally dissolved, the cities of Lubeck, Hamburg, and Bremen, sufficiently mark to what splendor and dignity this confederacy arrived.

Portugal and Spain next demand attention; and by subjects of these states, in a space of about fifty years, such discoveries were made as changed the whole face of affairs in the commercial world. The kingdom of Portugal was small, but well cultivated, very populous, and favored with a variety of good ports; which, with a succession of wise princes, who fostered the arts and sciences, encouraged industry, and extended the wealth and happiness of their subjects, prompted some lively spirits among them, about the beginning of the fifteenth century, to attempt discoveries in distant quarters. They were countenanced by a young heroic prince, who pushed on their endeavours with such success, that step by step the coast of Africa, was surveyed, as far as the Cape of Good Hope, which they thus named; and Vasquez de Gama at last happily discovered a new route to the East Indies, the point principally in view. Thus, in a short space of time, Portugal, from an inconsiderable power, grew one of the richest in Europe, gaining a vast accession of territory in Asia and Africa, and raising a naval power superior to any seen for ages preceding.

About the same time Christopher Colon, or Columbus, under the patronage of Isabella queen of Castile, and wife to Ferdinand the Wise, dis-

covered America: and, after Columbus's death, the discovery of a passage to the Spice Islands, which he aimed at, was perfected by Magellan.

The consequences that naturally followed on the discovery of a passage by the Cape of Good Hope, and of a fourth part of the globe in the western hemisphere, were, as before hinted, an entire change in the state of Europe, producing not only in Portugal and Spain, but in most other nations, a desire of visiting these remote parts, of establishing colonies and manufactures; of exporting commodities, and of raising, settling, and protecting, new establishments. Thus Europe in general received a lasting and invaluable benefit; and its potentates made themselves not only formidable, but even terrible, in those parts of the earth where before their fame was scarcely known.

The naval power of Portugal, which, as we have seen, was very great, received an incurable wound by falling under the power of Spain; and this alone, it would naturally be supposed, must have raised the latter to a monopoly of commerce, and the universal dominion of the sea; yet the very pursuit of a design so injurious to the interests of mankind, quickly ruined that power. The haughty temper of the Spaniards, fostered by the boundless ambition of their princes, obliged other nations, in their own defence, to pay more attention to navigation than they otherwise would have done. The English and Dutch, particularly, who had hitherto been blind to the advantages of their situation, were roused by the injuries they received; and the spirit of revenge prompted them to enterprise. In short, the pains taken by Spain to keep all the riches flowing from these discoveries to herself, and the dangerous, detestable, and destructive uses she made of those immense riches, produced effects directly opposite to those she looked for, and her enemies became rich, powerful, and happy, while her commerce dwindled away, and her naval power sunk and crumbled to pieces.

The inhabitants of the Seven Provinces, made poor by her oppression, and driven mad by her severities, shook off her yoke, and became potent and rich. They had learned by distresses the necessity of establishing a moderate and equal government; and the mildness of that government, with the blessings it procured to its subjects, increased their number, and elevated their hopes. The consequences were surprising both to friends and enemies; in a short time every fishing village was improved into a trading town; little towns grew up into large and magnificent cities; inland boroughs were filled with manufactures; and within half a century the oppressed states of Holland became high and mighty. Even amidst the danger and expenses of a war carried on against far superior forces these people attained a degree of political strength and importance which not only enabled them to defy the Spaniards, but made the latter glad to solicit their friendship.

None of the triumphs of commerce, either in ancient or modern history, were of so rapid or so strong a growth as this; and it will admit of no dispute, that the republic of the United Pro-

vinces owed her freedom, her power, and her wealth, entirely to industry and trade. The productions of their country would not support a tenth part of its inhabitants; they were without timber or maritime stores; without coal or lime; and their havens, though commodious, were difficult of entry. Yet these provinces were soon enriched; their store-houses became full of corn; their magazines contained every earthly commodity; their shipping was enormous, and their naval stores abundant. And the increase of their population was equally surprising. Had their land been pleasant and fruitful it would have been nothing strange; but that men should force nature, lay out gardens, raise palaces, dig canals, plant woods, and ransack all quarters of the earth for fruits and flowers, to make a paradise on a dead plain or ungrateful heath, in the midst of fogs and standing lakes, appears almost incredible.

The foreign commerce of BRITAIN, it may easily be conceived, must have been a work of time. The natives would first think of necessities, then of conveniences, and lastly of superfluities. Such tribes as came originally from the continent might have other ideas; but as we can only think of fear or indigence driving them hither, so it is likely that succeeding generations would fall off from the manners of their ancestors; and their circumstances affecting their desires would make them another sort of people. It is clear, however, that the inhabitants of the opposite continent, early maintained a foreign traffic, and came over and bartered their goods for the raw commodities of the Britons, till they gradually taught the latter to improve their leather and wicker boats, and to venture themselves over to Gaul.

Things were in this situation when the Romans invaded Britain, and by falling under that power our ancestors caught the manners and customs of their conquerors. At that time the arts and sciences flourished throughout the empire; with learning the Romans introduced foreign commerce everywhere, made excellent high roads, established colonies, and fixed standing camps and fortresses in proper places. These improvements were soon extended to Britain. They were also careful with regard to marts or emporiums for the conveniency of traders, of which they left many, and among the rest London, not more famous for her present extensive trade, than venerable for her antiquity. The abandonment of this island by the Romans was followed by a new deluge of barbarity: the Saxons effaced almost all the improvements of our civilised conquerors, and, upon the establishment as it were of a new people, things were to begin anew. Yet that they were inclined to, and made some advances in, foreign commerce, is sufficiently evident: Alfred the Great formed projects of vast discoveries to the north, and actually sent persons of great prudence and abilities into the east, who brought home various curiosities, which were preserved in the treasury of the church of Salisbury for many ages.

Though the Danes were our masters only a short time, yet from their becoming so by a maritime force, and from the establishment of their

countrymen on the opposite shores of France, as well as in the other parts of Europe, we may justly conclude that they corresponded with them, and that had their dominion continued longer it would have produced many advantages. But the Normans, men of the same race, dispossessed them here; and partly under color of right, partly by force, erected that monarchy, which, not without various alterations and changes, subsists even to our time.

We cannot here trace the ebbings and flowings of our commerce through every reign; but the opinion commonly entertained, that we had little or no trade before the time of Queen Elizabeth, seems to have but feeble support from history. The reign of that princess, however, was brilliant in every point of view. At her accession the finances of the nation were in a desperate condition; the crown was in debt, the treasury empty, the nation involved in a foreign war directly against her own interests, and our coasts naked. It had no credit abroad, nor concord at home; the great men were split into factions, and the common people distracted and dejected. In this sad situation of affairs, the first establishment of our commerce was effected. The government was compelled to act with caution, to draw assistance from every quarter, and to promote by every means the welfare of the people, both to support the expenses of the state, and to give a popular turn to her councils. Elizabeth encouraged her subjects to arm against the Spaniards, that they might be accustomed to the sea, and acquire a knowledge in navigation. She erected several companies, and was attentive to their pursuing the ends for which they were designed. During her whole reign, she particularly encouraged industry at home, and the honor of the country abroad; our commodities and manufactures were improved, the art of ship-building was brought to perfection, our ports were filled with able seamen, and English merchants were justly respected. In short, the seeds of British wealth, sown in her time, have been springing up ever since. See ENGLAND.

COMMERSIONIA, in botany, a genus of the pentagynia order, and pentandria class of plants: CAL. a monophyllous, five-parted, corolliferous perianth, with sharp ovated segments; COR. five linear petals; STAM. five very short filaments at the bases of the petals; pericarp a globular, hard, quinquelocular nut, with two ovated seeds in each division. Species one only; native of Otaheite and the South Sea Islands.

COMMIGRATE, *v. n.* } Lat. *con* and *mi-*
COMMIGRATION, *n. s.* } *gro.* To remove in a body, or by consent, from one country to another.

Both the inhabitants of that, and of our world, lost all memory of their *commigration* hence.

Woodward's Natural History.

COMMINATION, *n. s.* } Lat. *comminatio*.
COMMINATORY, *adj.* } A threat; a denunciation of punishment; a curse. The day of curses in the English church, otherwise called Ash-Wednesday, when the comminatory or denunciatory portions of the Levitical law are read, and all the people say *Amen*.

Some parts of knowledge God has thought fit to seclude from us; to fence them not only by precept and *commination*, but with difficulty and impossibilities.

Decay of Piety.

COMMINGLE, *v. a. & v. n.* Lat. *commisceo*. To mix into one mass; to unite intimately; to blend; to unite one with another.

Blest are those,

Whose blood and judgment are so well commingled,
That they are not a pipe for fortune's finger,
To sound what stop she please. *Shakspeare. Hamlet.*

Dissolutions of gum tragacanth and oil of sweet almonds do not *commingle*, the oil remaining on the top till they be stirred. *Bacon's Physical Remains.*

Thy fanes, thy temples, to thy surface bow,
Commingling slowly with heroic earth,
Broke by the share of every rustic plow:
So perish monuments of mortal birth,
So perish all in turn, save well recorded worth.

Byron's Child Harold.

COMMUNUTE, *v. a.* } Lat. *comminuo*. To
COMMUNIVABLE, *adj.* } grind; to pulverise;
COMMUNITION, *n. s.* } to break into small parts. It is also used in the sense of attenuation.

Causes of fixation are the even spreading of the spirits and tangible parts, the closeness of the tangible parts, and the jejuneness or extreme *communion* of spirits; of which the two first may be joined with a nature liquifiable. *Bacon.*

Parchment, skins, and cloth drink in liquors, though themselves be entire bodies, and not *communited*, as sand and ashes. *Id. Natural History.*

The best diamonds are *communivable*; and are so far from breaking hammers, that they submit unto pestilation, and resist not any ordinary pestle. *Broune.*

This smiting of the steel with the flint doth only make a *commination*, and a very rapid whirling and melting of some particles; but that idea of flame is wholly in us. *Bentley.*

COMMISERATE, *v. a.* } Lat. *con* and *mi-*
COMMISERABLE, *adj.* } *serior*. To pity;
COMMISERATION, *n. s.* } to compassionate.

It has relation to suffering, and more especially to suffering arising from criminality of conduct. A culprit dying under the penalty of the law excites our commiseration. Thus it is compassion peculiarly modified. Compassion is a call, a demand of nature, to relieve the unhappy. Commiseration is the sympathy which we feel with the guilty wretch, whose offence we deplore, but whose sorrows excite us to do all we can for his relief. Commiseration is represented as the feeling which our wretchedness excites in the Supreme Being. Commiseration is also the tenderness which we feel towards those who are below us in station or character, when they are overwhelmed with calamity.

These poor seduced creatures, whom I can neither speak nor think of but with much *commiseration* and pity. *Hooker*

Forgive a moiety of the principal
Glancing an eye of pity on his losses,
That have of late so huddled on his back;
Enough to press a royal merchant down,
And pluck *commiseration* of his state
From brassy bosoms, and rough hearts of flint,
From stubborn Turks, and Tartars, never trained
To offices of gentle courtesy. *Shakspeare.*

Live, and hereafter say

A mad man's mercy had thee run away.

— I do defy thy *commiseration*,
And apprehend thee for a felon here.

Id. Romeo and Juliet.

It is the sinfulness thing in the world to destitute a plantation once in forwardness: for besides the dishonour, it is the guiltiness of blood of many *commiserable* persons.

Bacon's Essays.

This was the end of this noble and *commiserable* person, Edward eldest son to the duke of Clarence.

Id. Henry VII.

She ended weeping; and her lovely plight
Immoveable, till peace, obtained from fault
Acknowledged and deplored, in Adam wrought
Commiseration.

Milton's Paradise Lost.

Then we must those, who groan beneath the weight
Of age, disease, or want, *commiserate.*

Denham.

We should *commiserate* our mutual ignorance, and endeavour to remove it.

Locke.

I prevailed with myself to go and see him, partly out of *commiseration*, and partly out of curiosity.

Swift.

CO'MMISSARY, *n. s.* } Bar. Lat. *commis-*
CO'MMISSARISHIP, *n. s.* } *sarius*. An officer made occasionally for a certain purpose; a delegate; a deputy. It is a title of ecclesiastical jurisdiction, appertaining to such as exercise spiritual jurisdiction, at least so far as his commission permits, in places of the diocese so far distant from the chief city, as the chancellor cannot call the subjects. An officer who draws up list of the numbers of an army, and regulates the procuration and conveyance of provision or ammunition.

The *commissaries* of bishops have authority only in some certain place of the diocese, and in some certain causes of the jurisdiction limited to them by the bishop's commission.

Ayliffe.

A *commissariship* is not grantable for life, so as to bind the succeeding bishop, though it should be confirmed by the dean and chapter.

Id. Parergon.

But is it thus you English bards compose?

With Runick lays thus tag insipid prose?

And when you should your heroes deeds rehearse,
Give us a *commissary's* list in verse.

Prior.

COMMISSARY-GENERAL, OF THE MUSTERS, an officer appointed to muster the army, to know the state of each regiment and company, to receive and inspect the muster rolls, and to keep an exact account of the strength of the army. A new appointment has been created in the person of inspector-general of cavalry, which answers every purpose for which that of muster-master general was intended, as far as regards the cavalry.

COMMISSARY-GENERAL, OF PROVISIONS, has the charge of furnishing the army in the field with all sorts of provision, forage, &c. by contract. He has under him various commissaries, store-keepers, clerks, &c.

COMMISSION, *n. s.* & *v. a.* } From com-
COMMISSIONATE, *v. a.* } mit, signifies
COMMISSIONER, *n. s.* } the act of committing, or putting into the power of another; a trust; a warrant by which any trust is held, or authority exercised. Charge; mandate; office; employment. A number of persons may be joined together to execute a trust, and they are a commission; and each individual is a commissioner. Commission is also used in the sense of

perpetration; the act of committing sin. Sins of commission are distinguished in theology from sins of omission.

Discrete he was, and of gret reverence;
He seemed swiche; his wordes were so wise:
Justice he was ful often in assise,
By patent, and by pleine *commissioun*.
For his science, and for his high renoun.

Chaucer. Cent. Tales.

Commission is the warrant, or letters patent, that all men exercising jurisdiction, either ordinary or extraordinary, have for their power.

Cowell.

Omission to do what is necessary,
Seals a *commission* to a blank of danger.

Shakespeare. Troilus and Cressida.

Comes through *commissions*, which compel from each
The sixth part of his substance, to be levied
Without delay.

Id. Henry VIII.

He led our powers;
Bore the *commission* of my place and person;
The which immediacy may well stand up,
And call itself your brother.

Id. King Lear.

It was both a strange *commission*, and a strange obedience to a *commission*, for men in the midst of their own blood, and being so furiously assailed, to hold their hands contrary to the laws of nature and necessity.

Bacon's War with Spain.

—What thou canst attain, which best may serve
To glorify thy Maker, and infer
Thee also happier, shall not be withheld
Thy hearing, such *commission* from above
I have received, to answer thy desire
Of knowledge within bounds.

Milton.

Draw no *commission* lest the court should lye,
And disavowing treaty ask supply.

Marvell.

As he was thus sent by his father, so also were the apostles solemnly *commissioned* by him to preach to the Gentile world, who, with indefatigable industry and resolute sufferings, pursued the charge; and sure this is competent evidence, that the design was of the most weighty importance.

Decay of Piety.

Every *commission* of sin introduces into the soul a certain degree of hardness.

South's Sermons.

He indulges himself in the habit of known sin, whether *commission* of something which God hath forbidden, or the omission of something commanded.

Roger's Sermons.

The archbishop was made one of the *commissioners* of the treasury.

Clarendon.

Suppose itinerary *commissioners* to inspect, throughout the kingdom, into the conduct of men in office, with respect to morals and religion, as well as abilities.

Swift.

I was made a colonel; though I gained my *commission* by the horse's virtues, having leapt over a six-bar gate.

Adison's Frecholder.

He for his son a gay *commission* buys,
Who drinks, whores, fights, and in a duel dies.

Pepe.

Like are their merits, like rewards they share;
That shines a consul, this *commissioner*.

Id. Dunciad.

'Tis pitiful
To court a grin when you should woo a soul;
To break a jest, when pity should inspire
Pathetic exhortation; and address
The scitish fancy with facetious tales,
When sent with God's *commission* to the heart.

Cooper.

COMMISSION, in commerce. See FACTORAGE.
COMMISSION OF BANKRUPTCY. See BANKRUPT.

COMMISSION OF LUNACY, issues out of the court of chancery, whether a person represented to be a lunatic, be so or not. See LUNACY.

COMMISSION OF TEINDS, a court at Edinburgh, which came in place of a committee of the Scottish parliament, for erecting new parishes, and valuing teinds for the support of the clergy. It is vested in the lords of session. See LAW.

COMMISSION, in military affairs, the situation of any officer (above a sergeant, who holds no commission) in his majesty's service, either in the line, the volunteers, or militia; in all of which, except the militia, the commissions must have the royal sign manual, and are issued from the war-office. Commissions in the militia do not bear the royal sign manual, but that of the lieutenant of the county,—they having previously been laid before his majesty for fourteen days to approve them.

COMMISSIONERS OF CUSTOMS. See CUSTOMS.

COMMISSIONERS OF EXCISE. See EXCISE.

COMMISSIONERS OF THE NAVY. See NAVY.

COMMISSIONERS OF THE TREASURY, LORDS. See EXCHEQUER, AND TREASURY.

COMMISSURE, *n. s.* Lat. *commissura*. Joint; a place where one part is joined to another.

All these inducements cannot countervail the inconvenience of disjoining the *commissures* with so many strokes of the chissel. *Wotton's Architecture*.

This animal is covered with a strong shell, jointed like armour by four transverse *commissures* in the middle of the body, connected by tough membranes.

Ray on the Creation.

COMMISSURE, among anatomists, is sometimes used for a suture of the cranium or skull. See SUTURE.

COMMISSURE, in architecture, &c. denotes the joint of two stones, or the application of the surface of the one to that of the other. See MASONRY. Commissure is also used by some authors for the small metuses or interstices of bodies, or the little clefts between the particles, especially when the particles are broadish and flat, and lie contiguous to one another, like thin plates or lamellæ.

COMMIT, *v. a.* } Lat. *committo*; Fr.

COMMITMENT, *n. s.* } *commettre*. To put to-

COMMITTEE, *n. s.* } } together; to put into a

COMMITTABLE, *adj.* } persons hands by way

of trust. It also signifies to perpetuate. It carries the idea of doing something wrong. In the first sense it is almost synonymous with commission, as commission, in one of its acceptations, is synonymous with commit. The kind of trust to which the verb very frequently refers, is that of committing, or sending to prison. Committee bears a striking analogy to commissories. Cowell thus explains its application:—"Those to whom the consideration or ordering of any matter is referred, either by some court to whom it belongs, or by consent of parties. As in parliament, after a bill is read, it is either agreed to and passed, or not agreed to; or neither of these, but referred to the consideration of some appointed by the house to examine it farther, who thereupon

are called a committee." Committer is a magistrate that sends a criminal to jail; or, the criminal who perpetrates the offence, that renders a jail his appropriate residence.

The mighty goddess also, of nature,
That under God hath the whole governance
Of worldly things committed to her cure,—
Disposed have, through her wise purveiance,
To give my lady so moche sullisance
Of al vertues.

Chaucer. Complaint of the Black Knight.

Thou ne shalt not also make no lesinges in thy
confession, for humilitee; peraventure, to say, that
thou hast committed and don swich sinnes of which
that thou ne were never guilty.

Id. The Persones Tale.

It is for your health, thus to commit
Your weak condition to the raw, cold morning.

Shakspeare.

Here comes the nobleman that committed the
prince, for striking him about Bardolph.

Id. Henry IV.

It did not appear by any new examinations or
commitments, that any other person was discovered or
impeached.

Bacon.

Besides the mistakes *committable* in the solary com-
pute, the difference of chronology disturbs his com-
pates.

Brown.

So, though my ankle she has quitted,
My heart continues still committed;
And, like a bailed and main-prized lover,
Although at large, I am bound over.

Hudibras

He'd prove a buzzard is no fowl,
And that a lord may be an owl,
A calf an alderman, a goose a justice,
And rookes *committe-men* and trustees.

Id.

A ravenous cat will punish in the mouse
The very same offences in the house
Which hee himselfe commits; yea, for that vice
Which was his own (with praise) hee kills the meic.

George Withers.

There, in a bribed *committee*, they contrive
To give our birth-rights to prerogative:
Give, did I say? They sell, and sell so dear,
That half each tax Danby distributes there.

Marvell.

Such an one makes a man not only a partaker of
other men's sins, but a deliver of the whole guilt to
himself, yet so as to leave the *committer* as full of
guilt as before.

South.

All corners were filled with covenanters, confusion,
committe-men, and soldiers, serving each other to their
ends of revenge, or power, or profit; and these *committe-men*
and soldiers were possess with this covenant.

Walton.

Manchester had orders to march thither, having a
committee of the parliament with him, as there was
another *committee* of the Scottish parliament always
in that army; there being also now a *committee* of
both kingdoms residing at London, for carrying on
the war.

Clarendon.

Letters out of Ulster gave him notice of the in-
human murders committed there upon a multitude of
the Protestants.

Id.

A creeping young fellow committed matrimony with
a brisk gamesome lass.

L' Etrange.

'Tis policy
For son and father to take different sides;
Then lands and tenements commit no treason.

Dryden.

Is my muse controuled
By servile awe? Born free, and not be bold!

At least I'll dig a hole within the ground,
And to the trusty earth *commit* the sound.

Id. Persius.

Vexed at the charge, I to the flames *commit*
Rhymes, similies, lord's names, and ends of wit.

Gay.

Whatever errors I may have *committed* in public
life, I have always loved my country. *Bolingbroke.*

Can you *commit* unchecked by shame
What in a beast so much you blame?

What is a law if those that make it

Become the forwardest to break it? *Beattie.*

COMMITMENT, in our law, takes place where the offence is not bailable, or the party cannot find bail. It must be by proper warrant, containing the cause of the commitment; and continues till put an end to by a trial, or in due course of law; imprisonment being intended only for safe custody, and not for punishment.

It is said, that wheresoever a justice of peace is empowered by any statute to bind a person over, or to cause him to do a certain thing, and such person, being in his presence, shall refuse to be bound, or to do such thing, the justice may commit him to the gaol to remain there till he shall comply. 2 Hawk. P. and C. cap. 16. §. 2. It also seems agreed by the old books, that wheresoever a constable or private person may justify the arresting another for a felony or treason, he may also justify the sending or bringing him to the common gaol; and that every private person has as much authority, in cases of this kind, as the sheriff or any other officer; and may justify such imprisonment by his own authority, but not by the command of another. *Id.* §. 3. But inasmuch as it is certain, that a person lawfully making such an arrest may justify bringing the party to the constable, in order to be carried by him before a justice of peace; and inasmuch as the statutes of 1 and 2 P. and M. cap. 13., and 2 and 3 P. and M. cap. 10., which direct in what manner persons brought before a justice of the peace for felony shall be examined by him, in order to their being committed or bailed, seem clearly to suppose, that all such persons are to be brought before such justice for such purpose; and inasmuch as the statute of 31 Car. II. cap. 2, commonly called the habeas-corpus act, seems to suppose that all persons who are committed to prison are there detained by virtue of some warrant in *writing*, which seems to be intended of a commitment by some magistrate, and the constant tenor of the late books, practice, and opinions, are agreeable hereto; it is certainly most advisable at this day, for any private person who arrests another for felony, to cause him to be brought, as soon as conveniently he may, before some justice of the peace, that he may be committed or bailed by him. The privy council and secretary of state may commit: but on an enquiry made into the source of this power in cases of libels and other state crimes, 2 Wils. 275, 11 S. T. 317. 9, it appears that the king being the principal conservator of the realm, the secretary of state has so much of the royal authority transferred to him as justifies commitment for these crimes, but not the seizure of papers. Respecting the manner of commitment, it is enacted by 2 and 3 P. and M. cap.

10, that justices of peace shall examine persons brought before them for felony, &c., or suspicion thereof, before they commit them to prison, and shall bind their accusers to give evidence against them. A justice of the peace may detain a prisoner a reasonable time, in order to examine him; and it is said, that three days is a reasonable time for this purpose. Every commitment must be in writing, and under the hand and seal, and show the authority of him that made it, and the time and place; and must be directed to the keeper of the prison. It may be either in the king's name, and only attested by the justice, or in the justice's name. And it ought to set forth the crime with convenient certainty, otherwise the officer is not punishable, by reason of such mittimus, for suffering the party to escape; and the court before whom he is removed by habeas corpus, ought to discharge or bail him.

Every such mittimus, again, ought to have a lawful conclusion, viz. that the party be safely kept till he be delivered by law, or by order of law, or by due course of law; or that he be kept till further order (which shall be intended of the order of law), or to the like effect; and if the party be committed only for want of bail, it seems to be a good conclusion of the commitment, that he be kept till he find bail: but a commitment till the person who makes it shall take further order, seems not to be good; and it seems that the party committed by such, or any other irregular mittimus, may be bailed. 2 Hawk. P. C. cap. 16. §. 18. A commitment grounded on an act of parliament ought to be conformable to the method prescribed by the statute; and all commitments must be to some prison within the realm.

COMMITTEE OF PARLIAMENT. At a select committee, although any member may be present, none can speak, or vote, but those named, for the committee; and the chairman has no more than a casting vote, when the parties are equal. Sometimes the whole house is resolved into a committee; on which occasion each person has a right to speak and reply as often as he pleases: an expedient they usually have recourse to, in extraordinary cases, and where any thing is to be thoroughly canvassed. When the house is not in a committee, each gives his opinion regularly, and is only allowed to speak once, unless to explain himself. The standing committees, appointed by every new parliament, are those of privileges and elections, of religion, of grievances, of courts of justice, and of trade; though only the former act.

COMMIT, *v. a.* } Lat. *commisceo*. To
COMMITION, *n. s.* } mingle; to blend; to
COMMITTION, *n. s.* } mix; to unite with
COMMITTURE, *n. s.* } things in one mass.
Union of various substances; in corporation.
The mass formed by mingling different things

Of Cerberus whylome he was begot,
And fell Chimæra, in her darksome den,
Through fowle *commixture* of his filthy blot;
Where he was fostred long in stygian fen,
Till he to perfect ripeness grew; and then
Into this wicked world he forth was sent
To be the plague and scourge of wretched men.

Spenser.

A dram of gold dissolved in aqua regia, with a dram of copper in aqua fortis, *commixed*, gave a great colour. *Bacon.*

In the *commixture* of any thing that is more oily or sweet, such bodies are least apt to putrefy, the air working little upon them. *Id. Natural History.*

Fair ladies, masked, are roses in the bud,
Or angels veiled in clouds, are roses blown;
Dismasked, their damask sweet *commixture* shown. *Shakespeare.*

Were thy *commixion* Greek and Trojan, so
That thou could'st say, this hand is Grecian all,
And this is Trojan. *Id. Troilus and Cressida.*

Some species there be of middle and participating natures, that is, of birds and beasts, as bats, and some few others, so conformed and set together, that we cannot define the beginning or end of either; there being a *commixtion* of both in the whole, rather than adaption or cement of the one unto the other. *Broun's Vulgar Errors.*

I have written against the spontaneous generation of frogs in the clouds; or, on the earth, out of dust and rain water *commixed*. *Ray on the Creation.*

All the circumstances and respect of religion and state intermixed together in their *commixture*, will better become a royal history, or a council-table, than a single life. *Wotton.*

Far in the sky they form their long array,
And land and ocean stretch'd immense survey
Deep, deep beneath; and triumphing in pride,
With clouds and winds *commixed*, innumerable ride. *Beattie.*

COMMIXTION, in Scots law, is a method of acquiring property, by mixing or blending together different substances belonging to different proprietors. See LAW.

COMMEDIATE, COMMODATUM, in the civil jurisprudence, the loan or free use of any thing movable or immovable for a certain time, on condition of restoring again the same individual after a certain term. There is this difference between a loan and a commodate, that the latter is gratis, and does not transfer the property; the thing must be returned in essence, and without impairment: so that things which consume by use or time cannot be objects of accommodate, but of a loan; in regard they may be returned in kind, though not in identity. See LAW.

COMMO'DE, *n. s.* The head-dress of women, French.

She, like some pensive statesman, walks demure,
And smiles, and hugs, to make destruction sure;
Or under high *commodes*, with looks erect,
Barefac'd devours, in gaudy colours deck'd. *Glanville.*

COMMODIANUS, of Gaza, a Christian author in the fourth century, who wrote a work in Latin verse, entitled *Institutiones*: M. Davies published a fine edition of it in 1711, at the end of *Minucius Felix*.

COMMO'DIOUS, *adj.* } Lat. *commodus*, or
COMMO'DIOUSLY, *adv.* } *con*, and *modus*. Ac-
COMMO'DIOUSNESS, *n. s.* } cording to the mea-
sure and degree required; fit; suitable; accom-
modate to any purpose without obstruction;
contrariety, or impediment; conveniently, easily,
pleasantly.

Wisdom may have framed one and the same thing to serve *commodiously* for divers ends. *Hooker.*

If they think we ought to prove the ceremonies *commodious*, they do greatly deceive themselves. *Id.*

The place requireth many circumstances; as the situation near the sea, for the *commodiousness* of an intercourse with England. *Bacon.*

Such a place cannot be *commodious* to live in; for being so near the moon, it had been too near the sun. *Raleigh's History.*

Bacchus had found out the making of wine, and many things else *commodious* for mankind. *Id. History of the World.*

He will instruct us praying, and of grace
Beseeching him, so as we need not fear
To pass *commodiously* this life sustained
By him with many comforts, till we end
In dust, our final rest and native home. *Milton.*

At the large foot of an old hollow tree,
In a deep cave seated *commodiously*,
His ancient and hereditary house,
There dwelt a good substantial country mouse. *Cowley.*

To that recess, *commodious* for surprise,
When purple light shall next suffuse the skies,
With me repair. *Pope's Odyssey.*

COMMO'DITY, *n. s.* In Latin *commoditas*, signifies in its abstract sense convenience; and in an extended application anything that is convenient or fit for use, which being also saleable, the word has been employed for things that are sold. Commodity is employed only for articles of the first necessity; accommodation, general convenience, particular advantage, are all senses in which it has been used by our best authors of the elder time. It is now more restricted in its application.

They knew, that howsoever men may seek their own *commodity*, yet if this were done with injury unto others, it was not to be suffered. *Hooker.*

There came into her head certain verses, which, if she had had present *commodity*, she would have rejoined as a retraction to the other. *Sidney.*

Travellers turn out of the highway, drawn either by the *commodity* of a foot-path, or the delicacy or the freshness of the fields. *Ben Jonson's Discoveries.*

Some offer me *commodities* to buy,
Even now a tailor called me in his shop,
And showed me silks that he had bought for me,
And, therewithal took measure of my body. *Shakespeare.*

Commodity, the bias of the world,
The world, which of itself is poised well,
Till this advantage, this vile drawing bias,
This sway of motion, this *commodity*,
Makes it take head from all indifferency,
From all direction, purpose, course, intent. *Id. King John.*

Commodities are movables, valuable by money, the common measure. *Locke.*

COMMODORE, *n. s.* Probably corrupted from the Spanish *commandador*. The captain who commands a squadron of ships; a temporary admiral.

COMMODORE, in the British marine, is a general officer, invested with the command of a detachment of ships of war destined on any particular enterprise, during which time he bears the rank of brigadier-general in the army, and is distinguished from the inferior ships of his squadron by a broad red pendant tapering towards the outer end, and sometimes forked. Commodore is also a name given to some select ship in a

fleet of merchantmen, which leads the van in time of war, and carries a light in her top to conduct the rest, and keep them together. The oldest captain in the fleet always commands.

COMMODUS (L. Aurelius Antoninus), the unworthy son of Marcus Antoninus, succeeded his father in the Roman empire, A. D. 180. His whole reign was a series of lust and folly, corruption and rapacity, injustice and cruelty. He kept 300 female concubines, and committed incest with all his sisters. Affecting to imitate Hercules, he wore a lion's skin, and carried a knotted club. He publicly fought with the gladiators, and boasted of his dexterity in killing the wild beasts in the amphitheatre. He required divine honors from the senate, and they were granted. Afraid to trust himself in the hands of a barber, he burnt his beard; but, by way of amusement, and under pretence of shaving his courtiers, he cut off their noses. Martia, one of his concubines, whom he had marked for death, poisoned him; but, as the poison did not quickly operate, he was strangled by a wrestler, A. D. 192; in the thirty-first year of his age, and the thirteenth of his reign. The servile senate no sooner heard of his death, than they ordered that the corpse of him, whom they had so lately deified, should rot upon a dunghill.

COMMOIGNE, in old records, a brother monk, residing in the same monastery.

COMMON, <i>n. s.</i>	} Lat. <i>com</i> and <i>munus</i> ; Fr. <i>commun</i> . 'The joint office or property of many. It has regard to the multitude of objects, and to those objects as possessed or accessible by everybody.
COMMON, <i>n. s.</i> & <i>adv.</i> from the <i>adj.</i>	
COMMONABLE, <i>adj.</i>	
COMMONAGE, <i>n. s.</i>	
COMMONALTY, <i>n. s.</i>	
COMMONER, <i>n. s.</i>	
COMMONLY, <i>adv.</i>	
COMMONNESS, <i>n. s.</i>	
COMMONS, <i>n. s.</i>	
COMMON-PLACE, <i>n. s.</i>	
COMMONWEAL, <i>n. s.</i>	}
COMMONWEALTH, <i>n. s.</i>	

It signifies abundant as opposed to rare and scarce; mean and vulgar as opposed to what is distinguished and noble: open and free as opposed to what is appropriated and enclosed; usual and customary as opposed to what is infrequent and singular; lower as opposed to higher, when applied to the houses of parliament. In composition, as in common-place book, it retains its general meaning, and signifies a book to be filled with a multitude of things, ranged, however, under general heads—and as in commonwealth, which signifies the public, the multitude, the general body of the people; or a civil polity and government, in which the many are interested, and which is or ought to be administered for their benefit.

This fierce arcite hath, of his helme, ydon;
And on a courser, for to shew his face,
He priketh endelong the large place,
Loking upward upon this emelie;
And she again him cast a frendlike eye,
(For women, as to speken in *commune*,
They folwen the favour of fortune)
And was all his in chere as his in hert.

Chaucer's *Canterbury Tales*.

Tyrants, that make men subject to their law,
I will suppress, that they no more may raine;
And lordings curbe that *commons* over-aw;
And all the wealth of rich men to the poore will draw.

Spenser.

Behold this ring,
Whose high respect and rich validity
Did lack a parallel: yet, for all that,
He gave it to a *communer* o' the camp. Shakspeare.

 Bid him strive
To gain the love o' the *commonalty*; the duke
Shall govern England. Id.

 My good lord,
How now for mitigation of this bill
Urged by the *commons*? Doth his majesty
Incline to it, or no? Id. Henry VI.

Look, as I blow this feather from my face,
And as the air blows it to me again,
Such is the lightness of you *common men*. Id.

This hand of yours requires
Much castigation, exercise devout;
For here's a strong and sweating devil here,
That *commonly* rebels. Id. Othello.

I am more than *common* tall. Id. As you like it.
Their sons are well tutored by you: you are a good
member of the *commonwealth*. Id. Love's Labour Lost.

Then take we down his load, and turn him off,
Like to the empty ass, to shake his ears,
And graze in *commons*. Id. Julius Caesar.

Two foundations bear up publick societies; the one
inclination, whereby all men desire sociable life; the
other an order agreed upon, touching the manner of
their union in living together: the latter is that which
we call the law of a *common-weal*. Hooker.

I myself too will use the secret acknowledgment of
the *commonalty*, bearing record of the God of Gods. Id.

Much good land might be gained from forests and
chases, and from other *commonable* places, so as there
be care taken that the poor *commoners* have no injury.
Bacon to Villiers.

Though life and sense be *common* to man and brutes,
and their operations in many things alike; yet by
this form he lives the life of a man, and not of a
brute; and hath the sense of a man, and not of a brute.
Hale's Origin of Mankind.

Flying bullets now,
To execute his rage, appear too slow;
They miss, or sweep but *common* souls away;
For such a loss Opdam his life must pay. Waller.

Or as the man, whom princes do advance
Upon their gracious mercy-seat to sit,
Doth *common* things, of course and circumstance,
To the reports of *common* men commit. Davies.

As the obsequious air and waters rest
'Till the dear Halcyon hatch out all its nest;
The *commonwealth* doth by its losses grow,
And, like its own seas, only ebbs to flow. Marvell.

The emmet jointed in her popular tribes
Of *commonalty*. Milton's Paradise Lost.

These three to kings and chiefs their scenes display,
The rest before the' ignoble *commons* play.

Dryden's Fables.

Is not the separate property of a thing the great
cause of its endearment? Does any one respect a
common as much as he does his garden? South.

The Papists were the most *common* place, and the
butt against whom all the arrows were directed.

Clarendon.

Where no kindred are to be found, we see the pos-
sessions of a private man revert to the community,
and so become again perfectly *common*; nor can any

one have a property in them, otherwise than in any other things *common* by nature. *Locke.*

Neither is it strange that there should be mysteries in divinity, as well as in the *commonest* operations in nature. *Swift.*

Blot out that maxim, *res nolunt diu male administrari*: the *commonness* makes me not know who is the author; but sure he must be some modern. *Id.*

There is hardly a greater difference between two things, than there is between a representing *commoner* in his public calling, and the same person in *common* life. *Id.*

This *commoner* has worth and parts,

Is praised for arms, or loved for arts:

His head aches for a coronet;

And who is blessed that is not great? *Prior.*

Hipparchus was going to marry a *common* woman, but consulted Philander upon the occasion. *Spectator.*

The peers are in some points, I speak it with all the respect due to them, *commoners* with coronets on their coats of arms; and, affecting to act as such, it is plain they desire very wisely to be taken for such, on many occasions. *Bolingbroke.*

A *huge common-place* book, wherein all the remarkable sayings and facts that we find in history are to be registered, may enable a man to talk or write like Bodin, but will never make him a better man, nor enable him to promote, like a useful citizen, the security, the peace, the welfare, or the grandeur of the community to which he belongs. *Id.*

A man may prescribe, in a quo estate, for a *common* appurtenant to a manor; but, if he would prescribe for a *common* in gross, he must prescribe in himself and his ancestors. *Blackstone's Commentaries.*

Amidst no *common* pomp the despot ate,
While busy preparations shook the court;
Slaves, eunuchs, soldiers, guests, and santons wait;
Within, a palace, and without, a fort;
Here men of every clime appear to make resort.

Byron's Child Harold.

COMMON, in grammar, such verbs as signify both action and passion are called common; as, *asperso*, I despise, or am despised; and also such nouns as are both masculine and feminine, as *parens*.

COMMON, in geometry, is applied to an angle, line, or the like, which belongs equally to two figures.

COMMON, in law, *communia* (i. e. *quod ad omnes pertinet*), signifies that soil, the use whereof is common to a particular town or lordship; or the profit that a man has in the land of another person, usually in common with others; or a right which a person has to put his cattle to pasture into ground that is not his own. And there is not only common of pasture, but also common of piscary, common of estovers, common of turbary, &c. And, in all cases of common, the law doth much respect the custom of the place; for there the rule is, *consuetudo loci est observanda*. See *COMMONTY*.

COMMONALTY, the lower of the two divisions of the civil state. See *CIVIL*. The commonalty, like the nobility, are divided into several degrees: and as the lords, though different in rank, are yet all peers in respect of their nobility; so the commoners, though some are greatly superior to others, are all in law commonalty, in respect to their want of nobility. This comprehensive term, therefore, includes—knights of the garter;

knights bannerets; baronets; and knights of the bath, not being otherwise peers; knights bachelors; all originally ranked as inferior degrees of nobility, though now classed as commoners: esquires; gentlemen; merchants; yeomen; tradesmen or artificers; laborers.

COMMONWEALTH, in English history, the title assumed by the government after the death of Charles I. under the protectorate of Cromwell, and till the restoration of Charles II. See *ENGLAND, HISTORY OF*.

COMMON COUNCIL. See *COUNCIL*.

COMMON DIVISOR, a quantity or number which exactly divides two or more other quantities or numbers, without leaving any remainder.

COMMON LAW contains those customs and usages which have, by long prescription, obtained in this nation the force of laws. It is distinguished from the statute law, which owes its authority to acts of parliament. See *LAW*.

By the *common* law any man might dispose of his lands to any other private man at his own discretion, especially when the feudal restraints of alienation were worn away. *Blackstone's Commentaries.*

COMMON-PLACE-BOOK is a register of what things occur, worthy to be noted, in the course of thinking or study, so disposed as that among a number of subjects any one may be easily found. The advantages of making a common-place book are many: it not only assists a person to read with accuracy and attention, but induces him to think for himself, provided he considers it not solely as a register of sentiments that strike him in the course of reading, but as a register of his own thoughts upon various subjects. There are various methods of arranging common-place books; that of Locke is as good as any that have hitherto been contrived. The first page is to serve as a kind of index to the whole, and to contain references to every place or matter therein: in the commodious contrivance of which index, so as it may admit of a sufficient variety of materials, without confusion, all the art consists. For this purpose, the first page, or, for more room, the two first pages that front each other, are to be divided, by parallel lines, into twenty-five equal parts; whereof every fifth line is to be distinguished by its color or other circumstance. These lines are to be crossed perpendicularly by others, drawn from top to bottom; and in the several spaces thereof, the several letters of the alphabet, both capital and minuscule, are to be duly written. The form of the lines and divisions, both horizontal and perpendicular, with the manner of writing the letters therein, will be conceived from the annexed diagram; in which what is to

be done in the book for all the letters of the alphabet, is here shown in the first four, *A, B, C,* and *D*. Suppose I would enter down a passage that refers to the head beauty, *B*, being the initial letter, and *e* the first vowel, I look in the

index for the partition *B*, and therein the line *c* (which is the place for all words whose first letter is *b*, and first vowel *c*; beauty, blemish, bread, &c.), and finding no numbers already down to direct me to any page of the book where words of this characteristic have been entered, I turn forward to the first blank page I find (which, in a fresh book, as this is supposed to be, will be page second), and here write what I have occasion for under the head beauty; beginning the head in the margin, and indenting all the other subsequent lines, that the leading word may be conspicuous. This done, I enter the page where it is, viz. 2. in the index in the space *Be*; from which time, the class *be* becomes wholly in possession of the second and third pages, which are consigned to letters of this characteristic.

COMMON PLEAS. A king's court now held in Westminster Hall, but anciently movable. 'The court of common pleas,' says Tomlins, 'does not possess any original jurisdiction; nor has it, like the court of king's bench, any mode of proceeding in common cases peculiar to itself. Its authority is founded on original writs issuing out of the court of chancery: which original writs are the king's mandates for the court to proceed in the determination of the causes mentioned therein. In all personal actions, therefore, brought by and against common persons, the only way of proceeding in this court is by original. There is indeed one other way of proceeding in this court, in common cases, which is sometimes used: and which is called proceeding by original quare clausum fregit. This method of proceeding is grounded, in point of law, upon the same kind of original writ as the usual proceeding by *capias* is, the only difference between them being in the mesne process after the original is sued out; or at least supposed so to be. Instead of the process to compel the appearance of the defendant being by *capias* against his person, it is in this case by summons and distress against his goods. In a word, it is the same as the ancient mode of proceeding in this court was, before the general introduction of the *capias*. The advantage and use of this mode of proceeding by original quare clausum fregit, is where a defendant has effects which can be distrained, but he himself cannot be met with to be personally served; the process by *capias* requiring personal service, which is not required in the process by summons. In this court are four judges, created by letters patent; the seal of the court is in the custody of the chief justice.

COMMON PRAYER, the 'liturgy of the' church of England. See **LITURGY**. Clergymen are to use the public form of prayers prescribed by the book of Common Prayer: and refusing to do so, or using any other public prayers, are punishable by stat. 1 Eliz. c. ii.

COMMONITION, n. s. Lat. *communitio*. Advice; warning; instruction.

COMMONS, n. s. } Food; fare; diet; so
COMMONER, n. s. } called from colleges, where it is eaten in common. A student of the second rank at the university of Oxford; one that eats at the common table.

He painted himself of a dove colour, and took his commons with the pigeons. *L'Estrange*.

Meanwhile she quenched her fury at the flood,
And with a lenten sallad cooled her blood:
Their commons, though but coarse, were nothing
scant;
Nor did their minds an equal banquet want.

Dryden.

The doctor now obeys the summons,
Likes both his company and commons. *Swift.*

COMMONS, or HOUSE OF COMMONS. See **PARLIAMENT**. The house of commons consists of members chosen from among such men of property in the kingdom as have no seats in the house of lords, every one of whom has thus a voice in parliament, either personally or by his representatives. In a free state, every man who is a free agent, ought to be in some measure his own governor; and therefore a branch at least of the legislative power should reside in the whole body of the people. It therefore is wisely contrived, that the people should do that, which it is impracticable for them to perform in person, by representatives chosen in a number of minute and separate districts, wherein all the voters are or may be easily distinguished. The counties are therefore represented by knights elected by the proprietors of lands; and the cities and boroughs by citizens and burgesses, chosen by the mercantile, or supposed trading interest of the nation. Each member, though chosen by one particular district, when elected and returned, serves for the whole realm; for the end of his coming thither is not particular but general; not barely to advantage his constituents, but the commonwealth. The peculiar laws and customs of the house of commons relate principally to the raising of taxes, and the elections of members to serve in parliament. See **ELECTIONS** and **TAXES**.

COMMONS, DOCTORS. See **COLLEGE**.

COMMONTY, in Scots law, sometimes signifies lands belonging to two or more common proprietors. Sometimes a heath or muir, though it should belong in property to one, if there has been a promiscuous possession upon it by pasturage; and the act 1695, mentions commonities belonging in property to the king and to royal boroughs. See **LAW**.

COMMORANT, adj. } Lat. *commorans*.
COMMORANCE, n. s. } Resident; dwelling;
COMMORANCY, n. s. } inhabiting.

The very quality, carriage, and place of *commorance*, of witnesses is plainly and evidently set forth. *Hale*.

An archbishop, out of his diocese, becomes subject to the archbishop of the province where he has his abode and *commorancy*. *Ayliffe's Parergon*.

The abbot may demand and recover his monk, that is *commorant* and residing in another monastery. *Id.*

COMMOTAU. See **COMETEAU**.

COMMOTE, an ancient term in Wales, denoting half a cantred, or hundred; containing fifty villages. See **HUNDRED**. Wales was anciently divided into three provinces; each of these subdivided into cantreds, and every cantred into two commotes or hundreds. Silvester Girald, however, tells us, in his Itinerary, that a commote is but a quarter of a hundred.

COMMOTION, n. s. } Lat. *commotio*. A
COMMOTIONER, n. s. } motion of several to-
gether. Tumult; insurrection; public dis-

order; perturbation; disorder of mind; restlessness. Applied to any object in motion.

By flattery he hath won the common hearts;
And, when he'll please to make *commotion*,
'Tis to be feared they all will follow him.

Shakspeare. Henry VI.

He could not debate any thing without some *commotion*, when the argument was not of moment.

Clarendon.

Sacrifices were offered when an earthquake happened, that he would allay the *commotions* of the water, and put an end to the earthquake.

Woodward. Natural History.

The people, more regarding *commotioners* than commissioners, flocked together, as clouds cluster against a storm.

Hayward.

COMMOLVE, *v. a.* Lat. *commovco*. To disturb; to agitate; to put into a violent motion; to unsettle. This word is now become obsolete.

Straight the sands,

Commovcd around, in gathering eddies play.

Thomson's Summer.

COMMUNE, *v. n.*

COMMUNICABILITY, *n. s.*

COMMUNICABLE, *adj.*

COMMUNICANT, *n. s.*

COMMUNICATE, *v. a. & v. n.*

COMMUNICATION, *n. s.*

COMMUNICATIVE, *adj.*

COMMUNICATIVENESS, *n. s.*

meaning, it refers not only to sentiments, but to anything that may become the common possession of more than one. Communicate is from the Latin *communicatus*, the participle of *communico*, contracted from *communifico*, which signifies to make common property with another. To impart to others what is in our own power; to bestow; to confer a joint possession. It is also a term of theological application, as the Lord's Supper is the boon which the blessed Redeemer has conferred upon all the members of his mystical body indiscriminately; they have all a joint and common interest in it; and when they receive it, as they ever ought to do, in society with each other, they are said to communicate; and the solemn festival is called 'The Communion.' It more generally means something in common to two or more, as the houses communicate, that is, there is a passage between them, by which either may be entered from the other. Communicative is used in the sense of free, unreserved, and the quality of those who are unworthy of confidence, more from their natural infirmity, than any privy of will or intention. Communion, likewise, is to be understood in the general sense of intercourse.

Contrition destroyeth the prison of helle, and maketh weke and feble all the strengthes of the devils, and restoreth the yeftes of the Holy Gost, and of all good vertues, and it clenseth the soule of sinne, and deliverth it fro the peine of helle, and fro the compaignie of the devil, and fro the servage of sinne, and it restoreth it to all goodes spiritual, and to the compaignie and *communion* of holy chirche.

Chaucer. The Persons Tale.

Consider, finally, the angels, as having with us that *communion* which the apostle to the Hebrews noteth; and in regard whereof angels have not disdained to profess themselves our fellow servants.

Hooker.

Communicants have ever used it; and we, by the form of the very utterance, do show we use it as *communicants*.

Id.

Sith eternal life is *communicable* unto all, it behooveth that the word of God be so likewise.

Id.

Charles the Hardy would *communicate* his secrets with none; and, least of all, those secrets which troubled him most.

Bacon.

I will *commune* with you of such things
That want no ears but yours.

Shakspeare. Measure for Measure.

Then *commune*, how that day they best may ply
Their growing work.

Milton's Paradise Lost.

The happy place

Rather inflames thy torment, representing
Lost bliss, to thee no more *communicable*.

Id. Paradise Regained.

The primitive Christians *communicated* every day.

Taylor.

Where God is worshipped, there he *communicates* his blessings and holy influences.

Id. Worthy Communicant.

Ideas, as ranked under names, are those that, for the most part, men reason of within themselves, and always those which they *commune* about with others.

Locke.

His majesty frankly promised, that he could not, in any degree, *communicate* to any person the matter, before he had taken and *communicated* to them his own resolutions.

Clarendon.

They resolved that the standing of the *communion* table in all churches should be altered.

Id.

Secrets may be carried so far, as to stop the *communication* necessary among all who have the management of affairs.

Swift.

We have paid for our want of prudence, and determine for the future to be less *communicative*.

Id. and Pope.

He is not only the most *communicative* of all beings, but he will also *communicate* himself in such measure as entirely to satisfy; otherwise some degrees of *communicativeness* would be wanting.

Norris.

A constant frequenter of worship, and a never-failing monthly *communicant*.

Atterbury's Sermons.

The map shows the natural *communication* providence has formed between the rivers and lakes of a country at so great a distance from the sea.

Addison on Italy.

When one that holds *communion* with the skies,
Has filled his urn where these pure waters rise,
And once more mingles with us meaner things,
'Tis even as if an angel shook his wings;
Immortal fragrance fills the circuit wide,
That tells us whence his treasures are supplied.

Cowper.

The whole body is nothing but a system of such canals, which all *communicate* with one another, mediately or immediately.

Arbuthnot on Aliments.

Those who speak in publick are better heard when they discourse by a lively genius and ready memory, than when they read all they would *communicate* to their hearers.

Watts.

'Tis said thou holdest converse with the things
Which are forbidden to the search of man;
That with the dwellers of the dark abodes,
The many evil and unheavenly spirits
Which walk the valley of the shades of death,
Thou *communest*.

Byron's Manfred.

Speed to thy castle, shut thy chamber door,
Bind fast thy soul by every solemn vow
Never to hold *communion* with that object.

Maturin's Bertram.

COMMUNES, in botany, the name of a class in Linnæus's *Methodis Calycina*, consisting of two plants which, like teasle and dandelion, have a calyx or flower-cup common to many flowers or florets. These are the aggregate or compound flowers of other systems.

COMMUNICATING, in theology, the act of receiving the sacrament of the eucharist. Those of the reformed, and of the Greek church, communicate under both kinds; the laity of the Romish, under only one. The oriental communicants receive the wine by a spoon, and anciently drank it through a pipe.

COMMUNICATION, LINES OF, in military affairs, trenches made to continue and preserve a safe correspondence between two forts or posts; or at a siege, between two approaches, that they may relieve one another.

COMMUNION, the celebration of the Lord's supper. The fourth council of Lateran decrees, that every believer shall receive the communion, at least, at Easter; but they did it much oftener in the primitive church. Gratian prescribes it as a rule for the laity, to communicate at Easter, Whitsuntide, and Christmas; and the council of Trent recommended frequent communion. So late as the ninth century, the communion was still received by the laity in both kinds; or rather the bread was dipped in the wine, as is owned by the Roman Catholics themselves. M. de Marca observes, that they received it at first in their hands, and believes the communion under one kind alone to have had its rise in the west under pope Urban II. in 1096, at the time of the conquest of the Holy Land. And it was more solemnly enjoined by the council of Constance in 1414. The twenty-eighth canon of the council of Clermont enjoins the communion to be received under both kinds, admitting only two exceptions: the first in favor of the sick, the second of the abstemious, or those who had an aversion for wine.

COMMUNION, FOREIGN, a punishment to which the canons frequently condemned their bishops and other clerks. This was a kind of suspension from the function of the order, and a degradation from the rank they held in the church. It had its name from the communion being only granted to the criminal on the footing of a foreign clerk. i. e. being reduced to the lowest of his order, he took place after all those of his rank, as all clerks, &c. did in the churches to which they did not belong. The second council of Agda orders every clerk who absents himself from the church, to be reduced to foreign communion.

COMMUNION, LAY, the communion under one kind. It was formerly a kind of canonical punishment, for clerks guilty of any crime, to be reduced to lay communion.

COMMUNION SERVICE, in the liturgy of the church of England, the office for the administration of the holy sacrament, extracted from several ancient liturgies, as those of St. Basil, St. Ambrose, &c. By the last rubric, part of this service is appointed to be read every Sunday and holiday, after the morning prayer, even though there be no communicants.

COMMUNITY, *n. s.* Lat. *communitas*, and *communis*. Its primary sense is simply the state

of being common: it has been extended, however, in its application—to those who are in a state of common possession; to the goods possessed as well as to the possessors; to the frequency or commonness of intercourse, or of observation. It also signifies the commonwealth, or body politic. 'Community in anything constitutes a community; a common interest; a common language; a common government is the basis of that community which is formed by any number of individuals.' 'Community has always a restricted and relative sense; in this it differs from society, which has a general and unlimited import.'—*Crabbe*.

He was but, as the cuckoo is in June,
Heard, not regarded; seen, but with such eyes,
As, sick and blunted with community,
Afford no extraordinary gaze. *Shakespeare.*

How could communities,
Degrees in schools, and brotherhood in cities,
But by degree stand in authentic place?
Id. Troilus and Cressida.

Sit up and revel,
Call all the great, the fair, and spirited dames
Of Rome about thee, and begin a fashion
Of freedom and community. *Ben Jonson.*

The undistinction of many in the community of name, or misapplication of the act of one unto the other, hath made some doubt thereof.

Broun's Vulgar Errors.

This text is far from proving Adam sole proprietor; it is a confirmation of the original community of all things. *Locke.*

It is not designed for her own use, but for the whole community. *Addison's Guardian.*

He lives not for himself alone, but hath a regard in all his actions to the great community. *Atterbury.*

COMMUTE, *v. a. & v. n.* } Lat. *commuto*.
COMMUTABILITY, *n. s.* } Literally to ex-
COMMUTABLE, *adj.* } change, to put one
COMMUTATION, *n. s.* } thing in the place
COMMUTATIVE, *adj.* } of another; to ransom
to; to alter. Commute is chiefly applied to the exchanging one mode of punishment for another; but commutative, relative to exchange, as commutative justice, that honesty which is exercised in traffic, and which is contrary to fraud in bargains.

The law of God had allowed an evasion, that is, by way of commutation or redemption. *Broun.*

Some commute swearing for whoring; as if forbearance of the one were a dispensation for the other.

L'Estrange.

An innocent nature could hate nothing that was innocent; in a word, so great is the commutation, that the soul then hated only that which now only it loves; i. e. sin. *South's Sermons.*

Those institutions which God designed for means to further men in holiness, they look upon as a privilege to serve instead of it, and to commute for it. *Id.*

COMMUTUAL, *adj.* Con and mutual. Mutual; reciprocal. Used only in poetry.

Love our hearts, and Hymen did our hands,
Unite commutual in most sacred bands. *Shakespeare. Hamlet.*

There, with commutual zeal, we both had strove
In acts of dear benevolence and love;
Brothers in peace, not rivals in command.

Pope's Odyssey

COMO, a lake of Italy, in the Milanese, and on the confines of Switzerland and the Grisons. It is the largest lake in Italy, being twenty-eight miles in length from north to south, from three to six in breadth, and eighty-eight in circumference. Towards the south it is divided into two branches; at the end of the one stands the town of Como, and at that of the other Lecco. The Adda runs through it; and its banks are adorned with vines, chestnuts, almond-trees, and various towns and villages.

Como, a populous city of Italy, in the department of Lario, and ci-devant province of Comasco, pleasantly situated in a valley, enclosed by fertile hills, on the south branch of the lake, near the source of the Adda. It was built by the Gauls under Brennus; and called Novocomum. It was the birth-place of Catullus, Jovius, and Pliny the younger; the last of whom, in his letters, speaks with rapture of its delightful situation, and the adjacent romantic scenery. It is surrounded by a wall, defended by towers, and backed by a conical eminence, on which are the ruins of an ancient castle. The houses are mostly built of stone, and the cathedral is a handsome edifice of white marble, hewn from the neighbouring quarries. It is a bishop's see, and contains twelve parish churches, and 15,000 inhabitants. On the outside of one of the churches is a statue of Pliny, with a Latin inscription, dated 1419. The inhabitants trade with the Grisons, and carry on manufactures of silks, cottons, &c. Como is twenty miles north of Milan, and eighty north-east of Turin.

COMORA, an island of Africa, in the Indian Ocean, which gives name to the cluster, of which it makes one. It is about sixty miles long, and fifteen broad, and composed of ranges of mountains, forming in the centre a summit of 7500 feet elevation. It contains many villages, which are resorted to and inhabited by Madagascar pirates. Long. 43° 10' E., lat. 11° 50' S.

COMORA ISLANDS, a cluster of islands lying between the north end of Madagascar and the coast of Zanguebar. Authors differ greatly with regard to their number, some enumerating five, others eight, and others only three. The names of five have been given us: Angezeia, Comora, Joanna, or Hinzuan, Mayotta, and Mobilia. They all abound in cattle, sheep, hogs, and a variety of fruits and animals common in warm countries. They are said also to produce a peculiar kind of rice. The most remarkable of them, and which Europeans are best acquainted with, is Joanna. The inhabitants are here about 7000 in number, and are chiefly settled inland. They pay a religious veneration to a species of ducks, which are very numerous, and inhabit a sacred lake. Of late years they have been much harassed by bands of desperate pirates, who occupy the north-western part of Madagascar. These cross every year by the south-west, with from thirty to fifty canoes, and return by the north-east monsoon. Their depredations are said nearly to have depopulated these islands.

COMORRA, the capital of a district of Hungary. It is so well fortified, that the Turks could never take it. The greatest part of the inhabitants are Hungarians and Russians, who are

very rich, and are of the Greek religion. It was almost destroyed by an earthquake in 1783. It is seated between the Danube and the Waag, in the island of Schut; thirty-six miles south-east of Presburg, and seventy of Vienna. Long. 18° 25' E., lat. 47° 50' N.

COMPACT, *n. s.* Lat. *pactum*. A contract; an accord; an agreement; a mutual and settled appointment between two or more, to do or to forbear something. It had anciently the accent on the last syllable.

I hope the king made peace with all of us;
And the *compact* is firm and true in me.

Shakspeare. Richard III.

In the beginnings of speech there was an implicit *compact*, founded upon common consent, that such words, voices, or gestures, should be signs whereby they would express their thoughts. *South.*

Hast thou *compacted* for a lease of years
With hell, that thus thou ventur'st to provoke me.

Dryden's Duke of Guise.

Thou false fiend, thou liest!

My life is in its last hour,—that I know,
Nor would redeem a moment of that hour;
I do not combat against death, but thee
And thy surrounding angels; my past power
Was purchased by no *compact* with thy crew.

Byron's Manfred.

COMPACT, *v. a. & adj.* Lat. *compactus*, the
COMPACTEDNESS, *n. s.* } participle of *compingo*.
COMPACTLY, *adv.* } Primarily to close; to
COMPACTNESS, *n. s.* } join together with
COMPACTURE, *n. s.* } firmness; to consolidate; to bring close together. Thus, secondarily, it signifies to league with; to bring into a system; the derivatives have the same meanings without variation.

We see the world so *compact*, that each thing preserveth other things, and also itself. *Hooker.*

Thou pernicious woman,
Compact with her that's gone, thinkest thou thy oaths,
Though they would swear down each particular fact,
Were testimonies? *Shakspeare. Measure for Measure.*

And over it a fair portellus hung,
Which to the gate directly did incline,
With comely compass, and *compacture* strong,
Neither unseemly short, nor yet exceeding long.

Faerie Queene.

A wandering fire,
Compact of unctuous vapour, which the night
And the cold environs around condenses,
Kindled through agitation to a flame. *Milton.*

Sticking or *compactness*, being natural to density, requires some excess of gravity in proportion to the density, or some other outward violence, to break it.

Digby on Bodies.

Is not the density greater in free and open spaces, void of air and other grosser bodies, than within the pores of water, glass, crystal, gems, and other *compact* bodies. *Newton's Opticks.*

The best lime mortar will not have attained its utmost *compactness*, till fourscore years after it has been employed in building. This is one reason why, in demolishing ancient fabrics, it is easier to break the stone than the mortar. *Boyle.*

This disease is more dangerous, as the solids are more strict and *compact*, and consequently more so as people are advanced in age. *Arbuthnot on Diet.*

Now the bright sun *compacts* the precious stone,
Imparting radiant lustre like his own.

Blackmore's Creation.

COMPAGES, *n. s.* Latin. A system of many parts united.

The organs in animal bodies are only a regular *compages* of pipes and vessels, for the fluids to pass through. *Ray.*

COMPAGINATION, *n. s.* Lat. *compago*. Union; structure; junction; connexion; con-texture.

The intire or broken *compagination* of the magneti-cal fabrick under it. *Broune's Vulgar Errors.*

COMPAGNIA DEL GONFALONE, (the com-pany of the standard), a society of players estab-lished in Rome in 1624, for the sole purpose of exhibiting, by dramatic representations, during the Easter week, the history and sufferings of Christ.

COMPANION, *n. s.* } French *compagnon*.
COMPANIONABLE, *adj.* } One with whom a
COMPANIONABLY, *adv.* } man frequently con-
COMPANIONSHIP, *n. s.* } verses, or with whom
he shares his hours of relaxation. It differs from friend, as acquaintance from confidence. A partner; an associate company; train; fel-
lowship; association.

How now, my lord? why do you keep alone?
Of sorriest fancies your companions make?

Shakspeare. Macbeth.

Alciades, and some twenty horse,
All of companionship. *Id. Timon.*

Bereaved of happiness, thou may'st partake
His punishment, eternal misery;
Which would be all his solace and revenge,
Thee once to gain companion of his woe. *Milton.*

He had a more companionable wit, and swayed
more among the good fellows. *Clarendon.*

With anxious doubts, with raging passions torn,
No sweet companion near with him to mourn.
Prior.

Thus Nisus wandered o'er the pathless grove,
To find the brave companion of his love. *Gay.*

While from his bending shoulder, decent hung
His harp, the sole companion of his way,
Which to the whistling winds responsive rung,
And ever as he went some merry lay he sung.
Beattie.

The desert, forest, cavern, breakers' foam,
Were unto him companionship; they spake
A mutual language, clearer than the tone
Of his land's tongue, which he would oft forsake
For Nature's pages glossed by sunbeams on the lake.
Byron's Child Harold.

COMPANY, *n. s. v. a. & v. n.* } Fr. *compag-*
COMPANABLENESS, *n. s.* } *nie*, either from
COMPANABLE, *adj.* } *con* and *pan-*
gnis, one of the same town; or *con* and *panis*,
one that eats of the same mess. Persons as-
sembled together. A body of people met for
any purpose, but more especially for the enter-
tainment of each other, either by conversation,
feasting, or any amusement; also the descrip-
tive term employed to designate persons united
in a joint trade or partnership: a number of
some particular rank or profession united by
charter; a body corporate. It is likewise ap-
plied to a subdivision of a regiment of foot, so
many as are under one captain: the adjective
signifies social, fond of amusement and frolic.

Duk Theseus, with all his *compagnie*,
Is comen home to Athones, his citee,
With alle blisse and gret solempnitee.

Chaucer's Canterbury Tales

As he thereon stood gazing, he might see
The blessed angels to and fro descend
From highest heaven in goodly *compance*,
And with great joy into that city wend,
As commonly as friend does with his friend.

Spenser.

Towards his queen he was nothing uxorious, but
companionable and respective. *Bacon's Henry VIII.*
A crowd is not *company*; and faces are but a
gallery of pictures, where there is no love.

Id. Essays.

It is more pleasant to enjoy the *company* of him
that can speak such words, than by such words to be
persuaded to follow solitariness. *Sidney.*

I am

The soldier that did *company* these three.

Shakspeare. Cymbeline.

Go, carry Sir John Falstaff to the Fleet;
Take all his *company* along with him.

Id. Henry IV.

But O my virgin lady, where is she,
How chance she is not in your *company*. *Milton.*
Thus, through what path soe'er of life we rove,
Rage *companies* our hate, and grief our love. *Prior.*

Knowledge of men and manners, the freedom of
habitudes, and conversation with the best *company* of
both sexes, is necessary. *Dryden.*

Shakspeare was an actor, when there were seven
companies of players in the town together. *Dennis.*

Abdallah grew by degrees so enamoured of her
conversation, that he did not think he lived when he
was not in *company* with his beloved Balsora.

Guardian.

This emperor seems to have been the first who in-
corporated the several trades of Rome into *companies*,
with their particular privileges. *Arbutnot on Coins.*

In fine, to converse with historians is to keep good
company: many of them were excellent men, and
those who were not such, have taken care, however,
to appear such in their writings. *Bolingbroke.*

COMPANY, in a commercial sense, persons
united in a joint trade or partnership. When
there are only two or three persons joined in this
manner, it is called a partnership; the term
company being applied to societies consisting of
a considerable number of members, associated
together by a charter obtained from the prince.

COMPANY, in commerce, is particularly appro-
priated to those associations set on foot for the
commerce of the remote parts of the world, and
vested by charter with peculiar privileges. These
associations are divided into general classes,
called Joint Stock Companies, and Regulated
Companies. Such companies, whether joint
stock or regulated, sometimes have, and some-
times have not, exclusive privileges. However
injurious companies with joint stock, and incor-
porated with exclusive privileges, may, at this
time, be reckoned to the nation in general, it is
yet certain, that they were the general parents of
all our foreign commerce; private traders being
discouraged from hazarding their fortunes in
foreign countries.

When a company trades upon a joint-stock,
each member sharing in the common profit or
loss in proportion to his share in this stock, it is
called a joint-stock company. Joint-stock com-

panies, however, established either by royal charter or by act of parliament, differ in several respects, not only from regulated companies, but from private copartneries. 1. In a private copartnery, no partner, without the consent of the company, can transfer his share to another person, to introduce a new member into the company. Each member however may, upon proper warning, withdraw from the copartnery, and demand payment from them of his share of the common stock. In a joint-stock company, on the contrary, no member can demand payment of his share from the company; but each member can, without their consent, transfer his share to another person, and thereby introduce a new member. The value of a share in a joint-stock is always the price which it will bring in the market; and this may be either greater or less, in proportion, than the sum which its owner stands credited for in the stock of the company. 2. In a private copartnery, each partner is bound only to the extent of his share. The trade of a joint-stock company is generally managed by a court of directors. The principal joint-stock companies in Great Britain are the South Sea and the East India Companies; to which may be added, though of inferior magnitude, the Hudson's Bay Company. See HUDSON'S BAY; INDIES, EAST, and SOUTH SEAS. The African, Turkey, and Russian Companies are rather regulated than made joint-stock companies by act of parliament. See AFRICAN COMPANY, &c. The anomalous and ephemeral projects of the last few years, we might almost say months, which have been designated as companies, we cannot be expected to notice. The exclusive privileges of all these associations have been thought at variance with that liberty which is the basis of fair trade; while their exemption from many of the liabilities of ordinary partnerships have offered great protection occasionally to knavish transactions. On the other hand, in the case of a public body, the capital it is said is matter of notoriety, and the responsibility of the individual partners admits of limitation, without injury to the creditors of the concern. But what say late events to this reasoning?

COMPANIES OF LONDON. See LONDON.

COMPANY, in military affairs, a small body of foot, commanded by a captain, who has under him a lieutenant and ensign. The number of private soldiers in a company is from fifty to 100; and a battalion, or regiment, consists of nine, ten, or eleven such companies, one of which is always grenadiers, and posted on the right: next them stands the colonel's company, and on the left the light infantry company. A company, moreover, has usually three or four serjeants, three or four corporals, and two drums. In the guards, the companies consist of 120 men each, as in the artillery. In the Austrian service a company consists of 200 men.

COMPANY, INDEPENDENT, or COMPANY, IRREGULAR, a company not incorporated into a regiment.

COMPANY OF SHIPS, a fleet of merchantmen, who make a charter-party among themselves: the principal conditions whereof usually are that

certain vessels shall be acknowledged admiral, vice-admiral, and rear-admiral; that such and such signals shall be observed; that those which bear no guns shall pay so much per cent. of their cargo; and, in case they be attacked, that what damages are sustained shall be reimbursed by the company in general. In the Mediterranean such companies are called *conserves*.

COMPANY'S ISLAND, or URIUP, an island in the North Pacific Ocean, about sixty miles in length, and thirty to forty-five in breadth. It appears to be uninhabited, and is in long. 151° 20' E., lat. 46° N.

COMPARE, <i>v. a.</i> & <i>v. n.</i>	} Lat. <i>comparo</i> ; Fr. <i>comparaison</i> . To make one thing the measure of another; to estimate the relative goodness or badness, or other qualities of any one thing, by observing how it differs from something else. It may be observed that when the comparison intends only similitude or illustration by likeness, we use <i>to</i> before the thing brought for illustration; as he compared anger <i>to</i> a fire. When two persons or things are compared, to discover their relative proportion of any quality, <i>with</i> is used before the thing used as a measure. Simile; similitude; illustration by comparison. In grammar, the comparative degree expresses more of any quantity in one thing than in another; as the right hand is the stronger. It is also the formation of an adjective, through its various degrees of signification; as strong, stronger, strongest.
COMPARABLE, <i>adj.</i>	
COMPARABLY, <i>adv.</i>	
COMPARATIVE, <i>adj.</i>	
COMPARATIVELY, <i>adv.</i>	
COMPARISON, <i>n. s.</i>	

This present world affordeth not any thing *comparable* unto the publick duties of religion. *Hooker*.

There resteth the *comparative*, that is, granted that it is either lawful or binding; yet whether other things be not to be preferred before the extirpation of heresies. *Bacon*.

The blossom is a positive good; although the remove of it, to give place to the fruit, be a *comparative* good. *Id*.

As fair and as good a kind of hand in hand *comparison*, had been something too fair and too good for any lady. *Shakspeare*.

I will hear Brutus speak. — *Id*
I will hear Cassius, and *compare* reasons.

Solon *compared* the people *unto* the sea, and orators and counsellors to the winds; for that the sea would be calm and quiet, if the winds did not trouble it.

As their small galleys may not hold *compare* With our tall ships. *Waller*.

Beyond *compare* the Son of God was seen Most glorious. *Milton's Paradise Lost*.

To *compare* Small things *with* greatest. *Id. Requined*.

If, wee with other things, man's age *compare*, His life is but a day, for, equalled are His years with hours; his months with minutes bee Fit paralels; and, every breathing, wee May terme a day yet, some, even at the night Of that short day, are dead, and withered quite.

Our author saves me the *comparison* with tragedy; for he says, that herein he is to imitate the tragick poet. *Dryden*.

He that has got the ideas of numbers, and hath taken the pains to *compare* one, two, and three to six, cannot chuse but know they are equal. *Locke.*

There could no form for such a royal use be *comparably* imagined, like that of the foresaid nation.

Wotton's Architecture.

Beauty is not known by an eye or nose; it consists in a symmetry, and it is the *comparative* faculty which notes it.

Glanville's Scep sis Scientifica.

The vegetables being *comparatively* lighter than the ordinary terrestrial matter of the globe, subsided last.

Woodward.

One can scarce imagine how so plentiful a soil should become so miserably unpeopled, in *comparison* of what it once was.

Addison's Remarks on Italy.

There is no blessing of life *comparable* to the enjoyment of a discreet and virtuous friend.

Id. Spectator.

Demosthenes used to *compare* eloquence to a weapon, aptly enough; for eloquence, like every other weapon, is of little use to the owner, unless he have the force and the skill to use it.

Bolingbroke.

And blooming Hyde with eyes so rare,

And Montague beyond *compare*. *Gay.*

The sun appears very bright and large in *comparison* of the fixed stars, because we keep constantly near the sun, in *comparison* of our immense distance from the stars.

Ferguson.

The bower of bliss, the smile of love be thine

Unlaboured ease, and leisure's careless dream,

Such be their joys who bend at Venus' shrine,

And own her charms beyond *compare* supreme.

Beattie.

Ah, then all jollity seemed noise and folly

To the pure soul by fancy's fire refined,

Ah, what is mirth, but turbulence unholy,

When with the charm *compared* of heavenly melancholy. *Id.*

Are not the mountains waves and skies, a part

Of me and of my soul, as I of them?

Is not the love of these deep in my heart

With a pure passion? Should I not condemn

All objects, if *compared* with these?

Byron. Child Harold.

COMPARATES, *n. s.* from *compare*. In logic, the two things compared to one another.

COMPARATIVE ANATOMY, or ZOOTOMY, is that branch of anatomy which has for its object the dissection and investigation of the various parts of the bodies of brutes. See ANATOMY.

COMPARATIVE DEGREE, in grammar, the degree between the positive and superlative. See GRAMMAR.

COMPARETTI (Andrew), an Italian physician, born in Friuli in 1746. He studied at Padua, and finally settled at Venice, where he published his *Occursus Medici*, and became in consequence professor of medicine in the university. In 1787 he published *Observationes de Luce Inflexa et Coloribus*, 4to., and, in 1789, *Observationes Anatomicae de Aure Interna Comparata*, 4to. After these appeared a *Treatise on Vegetable Physiology*; another on the *Moving Powers of Insects*; and several on *Practical Medicine*. He died, December 22nd, 1801, much respected.

COMPARISON. See GRAMMAR.

COMPARISON, in rhetoric and poetry, is a figure whereby two things are considered with regard to a third, common to both. Comparison may be employed with success in putting a sub-

ject in a strong point of view. A lively idea is formed of human courage, by likening it to that of a lion; and eloquence is exalted in our imagination by comparing it to a river overflowing its banks, and involving all in its impetuous course. The same effect is produced by contrast: a man in prosperity becomes more sensible of his happiness, by contrasting his condition with that of a person in want of bread. Objects of different senses cannot be compared together; for such objects have no circumstance in common to admit either resemblance or contrast. Objects of hearing may be compared together; as also of taste, of smell, and of touch; but the chief funds of comparison are objects of sight; because, in writing or speaking, things can only be compared in idea, and the ideas of sight are more distinct and lively than those of any other sense. When a nation, emerging out of barbarity, begins to think of the fine arts, the beauties of language cannot long lie concealed; and when discovered, they are, generally, by the force of novelty, carried beyond all bounds of moderation. Thus, in the most ancient poems of every nation, we find metaphors and similies founded on the slightest and most distant resemblances, which, losing their grace with their novelty, wear gradually out of repute: and now, by the improvement of taste, no metaphor nor simile is admitted into any polite composition but of the most striking kind.

COMPART, *v. a.* } Lat. *con* and *partior*;
 COMPARTMENT, *n. s.* } Fr. *comparter*, *com-*
 COMPARTITION, *n. s.* } *partition*. To divide;
 COMPARTMENT, *n. s.* } to mark out a general design into its various parts and subdivisions.

I will come to the *partition*, by which the authors of this art understand a graceful and useful distribution of the whole ground plot, both for rooms of office and entertainment. *Wotton.*

I make haste to the casting and *comparing* of the whole work. *Id. Architecture.*

The temples and amphitheatres needed no *compartitions*. *Id.*

The square will make you ready for all manner of *compartments*, bases, pedestals, and buildings.

Peacoch on Drawing.

The circumference is divided into twelve *compartiments*, each containing a complete picture. *Pope.*

COMPARTMENTS, in gardening, are an assemblage of beds, plots, borders, walks, &c. disposed in the most advantageous manner that the ground will admit of.

COMPARTMENTS, in heraldry, are also called partitions.

COMPASS, *v. a. & n. s.* Fr. *compasser*; Ital. *compassare*; Lat. *passibus metiri*. To encircle; to environ; to surround; to inclose: it has sometimes round, or about, added. Thus to defend to attack; to seize; to accomplish or attain any object, by a circuitous or indirect manner, or by strenuous efforts. The noun is derived from the verb, and partakes of primary meaning; it also signifies the power of the voice to express the notes of music; the instrument with which circles are drawn; but in this application rarely used in the singular; whence the instrument composed of a needle and card whereby mariners steer.

Of al this world, the large *compass*.

Will not in mine armes twine ;

Who so mokel wol embrace

Lite thereof shal distreine. *Chaucer's Proverbs.*

Round was the shape in manere of a *compass*

Ful of degrees, the hight of sixty pos,

That whan a man was set on no degree,

He letted not his felan for to see.

Id. Canterlary Tales.

What now is left, Clarinda ? what remains,

That we may *compass* this our enterprise. *Spenser.*

That which by wisdom he saw to be requisite for that people, was by as great wisdom *compassed*.

Hooker's Preface.

O Juliet, I already know thy grief ;

It strains me past the *compass* of my wits.

Shakspeare.

This day I breathed first ; time is come round ;

And where I did begin, there shall I end :

My life is run its *compass*. *Id. Julius Cæsar.*

I see thee *compassed* with thy kingdom's peers,

That speak my salutation in their minds.

Id. Macbeth.

In his hand

He took the golden *compasses*, prepared

In God's eternal store, to circumscribe

This universe, and all created things.

Milton's Paradise Lost.

And their mount Palatine,

The' imperial palace, *compass* huge, and high

The structure. *Id. Paradise Regained.*

He had a mind to make himself master of Weymouth, if he could *compass* it without engaging his army before it

Clarindon.

The knowledge of what is good and what is evil, what ought and what ought not to be done, is a thing too large to be *compassed*, and too hard to be mastered without brains and study, parts and contemplation.

South.

Certain it is, that in two hundred years before (I speak within *compass*) no such commission had been executed in either of these provinces.

Darvies on Ireland.

He that first discovered the use of the *compass*, did more for the supplying and increase of useful commodities, than those who built workhouses. *Locke.*

From harmony, from heavenly harmony,

This universal frame began :

From harmony to harmony

Through all the *compass* of the notes it ran,

The diapason closing full in man. *Dryden.*

To fix one foot of their *compass* wherever they think fit, and extend the other to such terrible lengths, without describing any circumference at all, is to leave us and themselves in a very uncertain state.

Swift.

The English are good confederates in an enterprize which may be dispatched in a short *compass* of time.

Addison's Freckholder.

This author hath tried the force and *compass* of our language with much success. *Swift.*

Tho' in your life ten thousand summers roll,

And tho' you *compass* earth from pole to pole,

Where'er men talk of war and martial fame,

They'll mention Marlborough and Cæsar's name.

Gay.

Now from the western mountain's brow

Compassed with clouds of various glow,

The sun a broader orb displays,

And shoots aslope his ruddy rays. *Beattie.*

Now must the pastor's arm his lambs defend :

For Spain is *compassed* by unyielding foes,

And all must share their all, or share subjection's woes. *Byron's Child Harold.*

COMPASS, an instrument of considerable use in surveying land, dialling, &c. Its structure is the same with that of the mariner's compass, consisting, like it, of a box and needle. The principal difference is, that instead of the needle being fitted into the card, and playing with it on a pivot, it here plays alone; the card being drawn on the bottom of the box, and a circle divided in 360° on the limb. This instrument is of obvious use to travellers, to direct them in their road; and to miners, to show them what way to dig, &c.

How to take an angle by the compass.—Suppose the angle required be DAE, apply that side of the compass, where—on the north is marked, to one of the lines AD; when the needle rests, observe the degrees at which its north point stands, which suppose eighty; so many degrees does the line decline from the meridian. In the same manner, take the declination of the line AE, which suppose 215°; subtract 80° from 215°, the remainder is 135°; which subtracted from 180°, there will remain 45°, the quantity of the angle required. But, if the difference between the declination on the two lines exceed 180°, in that case 180° must be subtracted from that difference: the remainder then is the angle required. In measuring angles by the compass, there need not any regard be had to the variation, that being supposed the same in all the lines of the angles.

How to take a plot of field by the compass.—Suppose the field A, B, C, D, E. For the greater

accuracy, let there be two sights fitted to the meridian line of the compass, place it horizontal, and through the sides look along the side AB, or a line parallel to it, applying the eye to the sight at the south point of the compass. Draw a rough sketch of the field by the eye, and on the corresponding line enter down the degree to which the needle points, which suppose 90; measure the length of the side, and enter that too, which suppose ten chains. In this manner proceed with all the rest of the sides and angles of the field; the sides, which suppose 70, 65, 70, 44, 50 fathom; and the angles, which suppose

30, 100, 130, 240, 300 degrees. To protract the field, set down the several angles observed, one after another, and subtract the lesser from the next greater: thus you will have the quantity of the several angles, and the length of the lines that include them. All the angles of the figure, taken together, must make twice as many right angles, abating two, if no mistake has been committed.

How to take the declination of a wall by the compass.—Apply that side of the compass whereon the north is marked along the side of the wall: the number of degrees, over which the north end of the needle fixes, will be the declination of the wall, and on that side; e.g. if the north point of the needle tends towards the north, that wall may be shone on by the sun at noon: if it fix over 50°, counting from the north towards the east, the declination is so many degrees from north towards east. But since the needle itself declines from the north towards the west with us, 13°, it must be noted, that, to retrieve the irregularity, 13° are always to be added to the degrees shown by the needle, when the declination of the wall is towards the east: but when the declination is towards the west, the declination of the needle is to be subtracted.

COMPASS, AZIMUTH. See AZIMUTH.

COMPASS, MARINER'S, the instrument used at sea by pilots, to direct and ascertain the course of their ships, consists of a circular brass box, which contains a paper card with the thirty-two points of the compass, fixed on a magnetic needle, that always turns to the north, excepting a small declination variable at different places. See VARIATION. The needle, with the card, turns on an upright pin fixed in the centre of the box. In the centre of the needle is fixed a brass conical locket or cap, whereby the card hanging on the pin turns freely round the centre. The top of the box is covered with a glass, that the motion of the card may not be disturbed by the wind. The whole is enclosed in another box of wood, where it is suspended by brass hoops or gimbals, to preserve the card horizontal. The compass-box is so placed in the ship, that the middle section of the box, parallel to its sides, may be parallel to the middle section of the ship along its keel. This important invention is usually ascribed to Flavio de Meli, or Flavio Giom, a Neapolitan, about the year 1302; and hence the territory of Principato, where he was born, has a compass for its arms. Others say, that Marcus Paulus, a Venetian, making a voyage to China, brought the invention with him in 1260. What confirms this is, that at first they used the compass in the same manner as the Chinese still do, i.e. they let it float on a little piece of cork, instead of suspending it on a pivot. It is added, that their emperor, Chininus, a celebrated astrologer, had a knowledge of it 1120 years before Christ. The Chinese only divide their compass into twenty-four points. Fauchette relates some verses of Guoyot de Provence, who lived in France, A. D. 1200, which seem to make mention of the compass under the name of *marinette*, or *mariner's stone*; which show it to have been used in France nearly 100 years before either the Mulite or the Venetian. The French even lay claim

to the invention, from the fleur-de-lis, wherewith all nations still distinguish the north point of the card. With equal reason, Dr. Wallis ascribes it to the English, from its name compass, and which he observes is used in many parts of England to signify a circle.

The compass being of the utmost consequence to navigation, it is reasonable to expect that the greatest attention should be paid to its construction, and every attempt to improve it carefully examined; and, if proper, adopted.

The very great objections to which the common compass is liable, induced the ingenious Dr. Knight to contrive a new sea-compass, which is now in use on board all the ships of war. The needle, in this instrument, is quite straight, and square at the ends; and, consequently, has only two poles, though, about the hole in the middle, the curves are a little confused. Needles of this construction, after vibrating a long time, will always point exactly in the same direction; and, if drawn ever so little on one side, will return to it again, without any sensible difference. We may, therefore, conclude, that a regular parallel-piped is the best form for a needle, as well as the simplest, the holes for the caps being as small as possible. And, as the weight should be removed to the greatest distance from the centre of motion, a circle of brass, of the same diameter of the card, may be added. This will serve also to support the card, which may then be made of thin paper, without anything to stiffen it. This ring being fixed below the card, and the needle above it, the centre of gravity is placed low enough to admit of the cap being put under the needle, whereby the hole in the needle becomes unnecessary. The above observations will be easily understood, from viewing the several parts of the instrument, as represented on plate COMPASS, where fig. 1 is the card, with the needle K L, and its cap M, fixed upon it, being one-third of the diameter of the real card. Fig. 2 is a perspective view of the back of the card, where A B represents the turning down of the brass edge, C the under part of the cap, D and E two sliding weights to balance the card, and F, G, two screws that fix the brass edge, &c. to the needle. Fig. 3 is the pedestal that supports the card, containing a screwing needle, fixed in two small grooves to receive it, by means of the collet C, in the manner of a port crayon. D, the stem, is filled into an octagon, that it may be the more easily unscrewed.

The compass has sometimes been observed to be disturbed by the electricity of its glass cover; and this from so slight an application of the finger, as was barely necessary to wipe off a little dust. The same glass, rubbed a little more with the finger, a bit of muslin, or paper, would attract either end of the needle, so as to hold it to the glass for several minutes, far out of the due direction, according to that part of the glass which was most excited. And when the needle, after adhering to the glass, has dropped loose, and made vibrations, these would not be bisected, as usual, by that point where the needle should rest, but would either be made all on one side, or be very unequally divided, by means of some remains of electrical virtue in that part of the

Fig. 1

Fig. 2

Fig. 1

Fig. 3

Fig. 4

Fig. 5

glass which had attracted the needle, until, at length, after fifteen minutes or more, all the electricity being discharged, the magnetical power took place. The remedy for this inconvenience is to moisten the surface of the glass; a wet finger will do it immediately and effectually. The mariner's compass, with a chart, is much less dangerously moved than the common compass with a bare needle; and the deeper, or farther distant, the needle hangs below the glass, the less disturbance it is likely to receive.

Notwithstanding the various contrivances that have been made to prevent the card from being much affected by the motions of the ship, they have always been found too delicate to encounter the shocks of a tempestuous sea. Improved compasses have been constructed by Mr. McCulloch, and for which he has obtained a patent, that are reported to be the best of any yet used. The particulars are as follow: plate COMPASS, fig. 4, is a section of the steering compass. *aaaaa*, the common wooden box, with its lid. *bb*, the brass compass-box. *cc*, the glass cover-to ditto. *dd*, the hollow conical bottom. *e*, the prop upon which the compass is supported, instead of gimbals, the spherical top of which is finely polished, and the apex of the hollow cone is fitted in a peculiar manner to receive it. *ff*, a quantity of lead run round the bottom and cone of the compass-box, to balance and keep it steadily horizontal. *gg*, the card and the magnetic needle, bent in such a manner, that the point of the conical pivot, on which it moves, and is supported, may be brought very near to the centre of gravity, as well as to the centre of motion. *hh*, two guards, which, by means of two pins, *ii*, affixed to the compass-box, prevents it from turning round and deceiving the steersman. Fig. 5 a perspective view of the steering compass, with the lid off and the front laid open. *h h*, the guards. *b*, the compass-box. *e*, the prop, &c. as in fig. 7. Fig. 6 is a section representing another application of the magnetic needle and card, constructed by Mr. McCulloch. *aaaa*, the common wood box. *bb*, the brass compass-box. *cc*, the brass support for the circle and pendulum. *d*, the pendulum. *e*, the agate. *ff*, the magnetic needle and card. *gg*, the brass circle. *hh*, the glass cover and brass ring. *i*, the lead weight. All the centres of motion are in the same plane. In one particular, this patent compass is considered as an improvement on the common compasses, inasmuch as the needle is both longer and broader; hence, its magnetism must be stronger, and of course the line of its magnetic direction correspondent with the card. In another particular, in order to prevent the motions of the vessel from affecting the needle, which is the most desirable object, the patent compass-box, instead of swinging in gimbals at right angles to each other, is supported in its very centre upon a prop; and, whatever motion the other parts of the box may have, this centre, being in the vertex of the hollow cone, may be considered as relatively at rest, and, therefore, gives little or no disturbance to the needle. Again, the pivot or centre upon which the needle turns, is so contrived as to stand always perpendicular over the centre of the compass-box,

an apex of the hollow cone, as upon a fixed point; and is, therefore, still less affected by the motions of the vessel. Thus, the centres of motion, gravity, and magnetism, are brought almost all to the same point; the advantages of which will be readily perceived by any person acquainted with mechanical principles. Experience, therefore, will ascertain the utility of this improvement.

COMPASS HILL, a hill in the isle of Canna, Scotland, remarkable for its effect on the polarity of the magnet.

COMPASSES, or PAIR OF COMPASSES, a mathematical instrument for describing circles, measuring figures, &c. The common compasses consist of two sharp-pointed branches or legs of iron, steel, brass, or other metal, joined together at the top by a rivet, whereon they move as on a centre. Those are best, wherein the pin or axle on which the joint turns, and also half the joint itself, is made of steel, as this metal wears more equably. The perfection of them may be known by the easy and uniform opening and shutting of their legs, one of which is sometimes made movable, for the admission of two other points to describe with ink, black lead, or other materials. One of these points has a small wheel for making dots. There are compasses of various kinds, accommodated to the various uses they are intended for: as,

COMPASSES, BEAM, consist of a long branch or beam, made of brass or wood, carrying two brass cursors, the one fixed at one end, the other sliding along the beam, with a screw to fasten it on occasion. To the cursors may be screwed points of any kind, whether steel for pencils, or the like. It is used to draw large circles, to take great extents, &c. To the fixed cursor is sometimes applied an adjusting micrometer screw, by which an extent is obtained to extreme nicety. Mr. Jones, of Holborn, has made beam compasses to adjust to the 5000th part of an inch.

COMPASSES, CLOCKMAKER'S, are joined like the common compasses, with a quadrant, or bow, like the spring compasses; only of different use, serving here to keep the instrument firm at any opening. They are made very strong, with the points of their legs of well tempered steel, being used to draw lines on paste-board or copper.

COMPASSES, CYLINDRICAL, AND SPHERICAL, consist of four branches, joined in a centre, two of which are circular, and two flat, a little bent on the ends. Their use is to take the diameter, thickness, or calibre of round or cylindrical bodies; such as cannons, pipes, &c.

COMPASSES, ELLIPTIC, are used to draw ellipses, or ovals of any kind: they consist of a beam, A, B, about a foot long, bearing three cursors; to one of which may be screwed points of any kind: to the bottom of the other two are rivetted two sliding dovetails, adjusted in grooves made in the cross branches of the beam. The dove-tails having a motion every way, by turning about the long branch, go backwards and forwards along the cross; so that when the beam has gone half way about, one of these will have moved the whole length of one of the branches; and when the beam has got quite round, the same dove-tail has got back the whole length of

the branch. It is the same with the other dovetail. The distance between the two sliding dovetails is the distance between the two foci of the ellipsis; so that, by changing that distance, the ellipsis will be rounder or slenderer. Under the ends of the branches of the cross are placed four steel points to keep it fast. The use of these compasses is easy; by turning round the long branch, the ink, pencil, or other point, will draw the ellipsis required.

COMPASSES, LAPIDARY'S, are a piece of wood in form of the shaft of a plane, cleft at top, as far as half its length; with this they measure the angles, &c. of jewels and precious stones, as they cut them. There is in the cleft a little brass rule, fastened at one end by a pin; but so that it may be moved in the manner of a brass level: with this kind of square they take the angles of the stones, laying them on the shaft as they cut them.

COMPASSES OF THREE LEGS, or TRIANGULAR COMPASSES, are of the same structure with the common ones, but have an additional leg: their use is to take three points at once, and so to form triangles; to lay down three positions of a map to be copied at once, &c.

COMPASSES, PROPORTIONAL, are those whose joint lies between the points terminating each leg; they are either simple, or compound. In the simple, the centre is fixed, so that one pair serves only for one proportion. The compound, consists of two parts or sides of brass, which lie upon each other so nicely as to appear but one when they are shut. These sides easily open, and move about a centre, which is itself movable

in a hollow canal cut through the greatest part of their length. To this centre on each side is affixed a sliding piece, A, fig. 1, of a small length, with a fine line drawn on it serving as an index, to be set against other lines or divisions placed upon the compasses on both sides. These lines are, 1. A line of lines. 2. A line of superficies, or areas, or planes. 3. A line of solids. 4. A line of circles, or rather of polygons to be inscribed in circles. These lines are all unequally divided; the first three from 1 to 20, the last from 6 to 20. Their uses are as follow: By the line of lines you divide a given line into any number of equal parts; for by placing the index A against 1, and screwing it fast, if you open the compasses, then the distance between the points at each end will be equal. If you place the index against 2, and open the compasses, the distance between the points of the longer legs B B, will be twice the distance between the shorter ones C C; and thus a line is bisected, or divided into two equal parts. If the index be placed against 3, and the compasses opened, the distances between the points will be as 3 to 1, and so a line is divided into two equal parts; and so you proceed for any other number of parts under 10. The numbers of the line of planes answer to the squares of those in the line of lines; for, because superficies or planes are to each other as the squares of their like sides; therefore, if the index be placed against 2 in the line of planes, then the distance between the small points will be the fine of a plane whose area is one; but the distance of the larger points will be the like side of a plane whose area is two; or twice as large. If the index be placed at 3, and the compasses opened, the distances between the points at each end will be the like side of planes whose area are as 1 to 3; and so of others. The numbers of the line of solids answer to the cubes of those in the line of lines; because all solids are to each other as the cubes of their sides or diameters; therefore, if the index be placed to number 2, 3, 4, &c. in the line of solids, the distance between the lesser and larger points will be the like sides of solids, which are to each other as 1 to 2, 1 to 3, 1 to 4, &c. For example: if the index be placed at 10, and the compasses be opened, so that the small points may take the diameter of a bullet whose weight is one ounce, the distance between the large points will be the diameter of a bullet or globe of ten ounces, or which is ten times as large. Lastly, the numbers in the line of circles are the sides of polygons to be inscribed in a given circle, or by which a circle may be divided into equal parts, from 6 to 20. Thus, if the index be placed at 6, the points of the compasses at either end, when opened to the radius of a given circle, will contain the side of a hexagon, or divide the circle into six equal parts. And thus, by placing the index at 7, 8, &c. we may divide it into seven or eight parts, and inscribe heptagons, octagons, &c.

COMPASSES, SPRING, or DIVIDERS, those with an arched head, which by its spring opens the legs; the opening being directed by a circular screw fastened to one of the legs, and let through the other, worked with a nut.

COMPASSES, TRISECTING, consist of two central rules, and an arch of circles of 120 degrees,

immovable, with its radius; which is fastened with one of the central rules like the two legs of a sector, that the central rule may be carried through all the points of the circumference of the arch. The radius and rule should be as thin as possible; and the rule fastened to the radius should be hammered cold, to attain the greater elasticity; and the breadth of the central rule should be triple that of the radius; there must also be a groove in this rule, with a dove-tail fastened on it for its motion, and a hole in the centre of each rule. The use of this instrument is to facilitate the trisection of angles geometrically; and it is said to have been invented by M. Targen.

COMPASSION, *n. s. & v. a.* } Fr. *compassion*; by nature the most *compatible*; valour with anger, meekness with piety, and prudence with dissimulation. }
 COMPASSIONATE, *v. a.* } *sion*; from Lat. *con* and *patior*.
 COMPASSIONATELY, *adv.* }
 Pity; commiseration; sorrow for the sufferings of others; painful sympathy; a call; a demand of nature to relieve the unhappy; pitiful tenderness.

I am your patroness,

Therefore, ye ought to have some *compassion*.

Chaucer. The Complaint of Mars.

But the wyld man, contrarie to her feare,
 Came to her creeping like a fawning hound,
 And by rude tokens made to her appeare
 His deepe *compassion* of her doleful stound,
 Kissing his hands, and crouching to the ground.

Spenser.

Experience layeth princes torn estates before their eyes,
 and withal persuades them to *compassionate* themselves.

Raleigh.

O heavens! can you hear a good man groan,
 And not relent, or not *compassion* him?

Shakspeare. Titus Andronicus.

here never was any heart truly great and generous,
 that was not also tender and *compassionate*.

South's Sermons.

Their angry hands

My brothers hold, and vengeance these exact;
 This pleads *compassion*, and repents the fact.

Dryden's Fables.

Envy, stern tyrant of the flinty heart,

Can aught of Virtue, Truth, or Beauty charm?

Can soft *Compassion* thrill with pleasing smart,

Repentance melt, or Gratitude disarm. *Beattie.*

The fines were assigned to the rebuilding of St. Pauls', and thought therefore to be the more severely imposed, and the less *compassionately* reduced and excused.

Clarendon.

The good-natured man is apt to be moved with *compassion* for those misfortunes or infirmities, which another would turn into ridicule. *Addison's Spectator.*

COMPASSION, or COMMISERATION, in ethics, a mixed passion, compounded of love and sorrow, and excited by the sight or recital of distress. Hobbs makes this a merely selfish passion, and defines it, as being fear for ourselves; Hutchinson resolves it into instinct; but Dr. Butler more properly considers compassion as an original, distinct, particular affection in human nature.

COMPATERNITY, *n. s.* Lat. *con* and *pater-nitas*.

Gossipred, or *compaternity*, by the canon law, is a spiritual affinity; and a juror that was gossip to either of the parties might, in former time, have been challenged as not indifferent by our law.

Davies's State of Ireland.

COMPATIBLE, *adj.* } Corrupted by an
 COMPATIBILITY, *n. s.* } unskilful compliance
 COMPATIBLENESS, *n. s.* } with pronunciation,
 COMPATIBLY, *adv.* } from *competibile*, from
 Lat. *competo*, to suit, to agree. *Competibile* is found in good writers, and ought always to be used. Crabb derives it from *con* and *patior*, which signifies fitness to be suffered together. Consistency; the power of co-existing with something else; agreement with anything; suitable to; fit for; consistent with; opposed to every thing that is incongruous.

The object of the will is such a good as is *compatible* to an intellectual nature.

Hale's Origin of Mankind.

Our poets have joined together such qualities as are by nature the most *compatible*; valour with anger, meekness with piety, and prudence with dissimulation.

Broomer.

COMPATIENT, *adj.* from Lat. *con* and *patior*. Suffering together.

COMPATRIOT, *n. s.* from Lat. *con* and *patrio*. One of the same country.

The governor knew he was so circumspect as not to adhere to any of the factions of the time, in a neutrality indifferently and friendly entertaining all his *compatriots*.

Drummond.

COMPANER, *n. s. & v. a.* Lat. *compar*, equal; companion; colleague; associate.

Therein dwelt a burghouse, the most selipier man,
 Of all the town throughout; and whatso he wan
 With treachery and gile, as doth some peres,
 Right so must he part with his *compers*.

Chaucer. Cant. Tales.

In his own grace he doth exalt himself
 More than in your advancement.

—In my right,

By me invested, he *compers* the best.

Shakspeare. King Lear.

So spake the apostate angel, though in pain
 Vaunting aloud, but racked with deep despair,
 And him thus answered soon his bold *compere*.

Milton.

For Bordeaux we with voice unanimous

Declare such sympathy's in boon *compers*. *Gay.*

Sesostris,

That monarchs harnessed, to his chariot yoked,
 Base servitude, and his dethroned *compers*
 Lashed furiously.

Philips.

COMPEL, *v. a.* } Lat. *compello*, or *pello*,
 COMPELLABLE, *adj.* } to drive for a specific
 COMPELLER, *n. s.* } purpose, or to a point;
 to urge irresistibly; to take by force or violence;
 to gather together and unite in company. A latinism *compellere gregem*; to seize; to empower.

So him dismounted low he did *compell*

On foot with him to matchen equal fight.

Spenser.

You will *compel* me then to read the will?

Shakspeare. Julius Cæsar.

But first the lawless tyrant, who denies
 To know their God, or message to regard,
 Must be *compelled* by signs and judgments dire.

Milton.

Our men secure nor guards nor entries held,
 But easy sleep their weary limbs *compelled*.

Dryden.

Yet has not oft the fraudful guardian's fright,
 Compelled him to restore an orphan's right. *Gay*

The clouds above me to the white Alps tend,
And I must pierce them, and survey whate'er
May be permitted, as my steps I bend
To their most great and growing region, where
The earth to her embrace *compels* the powers of air.

Byron's Child Harold.

COMPELLATION, *n. s.* Lat. from *compello*. The style of address; the word of salutation.

The stile best fitted for all persons, on all occasions, to use, is the *compellation* of Father, which our Saviour first taught. *Duppa's Rules of Devotion.*

The peculiar *compellation* of the kings in France, is by sire, which is nothing else but father. *Temple.*

COMPENDIUM, *n. s.* } Lat. *compendium*, *compendiaris*. Abridgement; summary; breviate; abbreviate; that which holds much in a limited space. Mr. Crabbe has thus distinguished the modes of meaning between two words that are erroneously considered to be synonymous. 'An abridgement, he observes, is the reduction of a work into a smaller compass. A compendium is a general and concise view of any science, as geography or astronomy.'

By the apostles we have the substance of Christian belief *compendiously* drawn into few and short articles. *Hooker.*

The inviting easiness and *compendiousness* of this assertion, should dazzle the eyes. *Bentley's Sermons.*

After we are grown well acquainted with a short system, or *compendium* of a science, which is written in the plainest and most simple manner, it is then proper to read a larger regular treatise on that subject. *Watts on the Mind.*

Fix in memory the discourses, and abstract them into brief *compendia*. *Id. Improvement on the Mind.*

They learned more *compendious* and expeditious ways, whereby they shortened their labours, and gained time. *Woodward.*

COMPENSATE, *v. a.* } Lat. *compenso*; } compounded of *com* }
COMPENSE, *v. a.* } } *pensatio*; } *pcnsus* }
COMPENSABLE, *adj.* } } and *pendo*. To pay; }
COMPENSATION, *n. s.* } } hence to recom- }
COMPENSATIVE, *adj.* } } pense; to make amends; }
to counterbalance a loss by an equivalent. Making up a deficiency, atoning, or satisfying for an injury.

Poynings, the better to make *compensation* of his service in the wars, called a parliament. *Bacon.*
The length of the night, and the dews thereof, do *compensate* the heat of the day. *Id. Natural History.*

It seemeth, the weight of the quicksilver doth not *compense* the weight of a stone, more than the weight of the aqua fortis. *Id.*

All other debts may *compensation* find;
But love is strict, and will be paid in kind.

Dryden's Aurengzebe.
The pleasures of life do not *compensate* the miseries. *Prior.*

Nature to these, without profusion kind,
The proper organs, proper powers, assigned;
Each seeming want *compensated* of course,
Here with degrees of swiftness, there of force.

Popc.

Compensation is a species of relation. It is relation when the defects of one part, or of one organ, are supplied by the structure of another organ.

Paley's Theology.

COMPENSATION, in law. Where the same person is debtor and creditor, the mutual obligations, if they are for equal sums, are extinguished by compensation; if for unequal, the lesser obligation is extinguished, and the greater diminished, as far as the concurrence of debt and credit goes.

COMPENENDINATE, *v. a.* } Lat. *com-*
COMPENENDINATION, *n. s.* } *perendino*; to }
delay; delay; dilatoriness.

COMPETENT, *adj.* } Latin *competens*.
COMPETENCE, *n. s.* } Suitable; fit; ade- }
COMPETENCY, *n. s.* } quate; proportion- }
COMPETENTLY, *adv.* } ate; adapted to any }
purpose without defect or superfluity. Capacity, applied to intellectual power and judicial authority. Ability equal to any given task; official right to decide on any given question. It is also used in the sense of reasonable and moderate.

If there be any power in imagination, the distance must be *competent*, the medium not adverse, and the body apt and proportionate.

Bacon's Natural History.

To draw men from great excess, it is not amiss, though we use them unto somewhat less than is *competent*. *Hooker.*

For *competence* of life I will allow you,
That lack of means enforce you not to evil. *Shakespeare. Henry IV.*

The greatest captain of the English brought rather a guard, than a *competent* army, to recover Ireland. *Davies on Ireland.*

That is the privilege of the Infinite Author of things, who never slumbers nor sleeps, but is not *competent* to any finite being. *Locke.*

I think it hath been *competently* proved. *Bentley.*

Something of speech is to be indulged to common civility, more to intimacies, and a *competency* to those recreative discourses which maintain the cheerfulness of society. *Government of the Tongue.*

Some places require men *competently* endowed; but none think the appointment to be a duty of justice bound to respect desert. *Wotton.*

Reason's whole pleasure, all the joys of sense,
Lie in three words, health, peace, and *competence*. *Pope.*

There are who deaf to mad Ambition's call,
Would shrink to hear the obstreperous trump of Fame,
Supremely blest if to their portion fall
Health, *competence* and peace. *Beattie.*

A *competency* ought to secure a man from poverty; or if he wastes it makes him ashamed of publishing his necessities. *Johnson's Life of Dryden.*

COMPETENTES. See **CATICHUMENS**.

COMPETIBLE, *adj.* } See **COMPATIBLE**.
COMPETIBLENESS, *n. s.* }

Those are properties not at all *competible* to body or matter, though of never so pure a mixture. *Glanville.*

It is not *competible* with the grace of God so much as to incline any man to do evil.

Hammond on Fundamentals.

COMPETITION, *n. s.* Lat. *con* and *petitio*; and *competo*, the verb, which signifies to seek together the same object, with an emulous desire of success to ourselves: hence rivalry, contest. It also signifies double claim; claim of more than one to one thing.

The ancient flames of discord and intense wars, upon the *competition* of both houses, would again return.

Bacon.

Competition to the crown there is none, nor can be.

Id.

For God,

Nothing more certain, will not long defer

To vindicate the glory of his name

Against all *competition*, nor will long

Endure it doubtful, whether God be Lord

Or Dagon.

Milton's Samson Agonistes.

Though what produces any degree of pleasure be in itself good, and what is apt to produce any degree of pain be evil, yet often we do not call it so when it comes in *competition*; the degrees also of pleasure and pain have a preference.

Locke.

The prize of beauty was disputed till you were seen; but now all pretenders have withdrawn their claims: there is no *competition* but for the second place.

Dryden.

COMPETITOR, *n. s.* Lat. *con* and *petitor*. An opponent; one that has a claim opposite to another's; a rival.

The Guilfords are in arms,

And every hour more *competitors*

Flock to the rebels. *Shakspeare. Richard III.*

How furious and impatient they be,

And cannot brook *competitors* in love.

Id. Titus Andronicus.

Selymes, king of Algiers, was in arms against his brother Mechemetes, *competitor* of the kingdom.

Knolles's History.

COMPIEGNE, or **COMPEIGNE**, a handsome old town of France, in the department of Oise, and ci-devant province of the Isle of France. The heroic maid of Orleans was taken prisoner here in 1430. It is seated near a large forest, at the confluence of the Aisne and the Oise, and contains several churches, one of which possesses the first organ ever seen in France. The palace of Compiègne was a favorite hunting seat of the French monarchs. Population 1290. It is forty-eight miles north-east of Paris. Long. 2° 55' E., Lat. 49° 25' N.

COMPILE, *v. a.* } Lat. *compilo*. To write;
COMPILATION, *n. s.* } to compose; to draw up
COMPLEMENT, *n. s.* } from various authors, to
COMPILER. } collect into one body;
 to contain; to comprise, not used. Compilation is applied generally to an assemblage or coaceration, as in the following instance:—

There is in it a small vein filled with spar, probably since the time of the *compilation* of the mass.

Woodward on Fossils.

After so long a race as I have run
 Through fairy land, which those six books *compile*,
 Give leave to rest me. *Spenser.*

I was encouraged to assay how I could build a man; for there is a moral as well as a natural or artificial *complement*, and of better materials.

Wotton on Education.

Some painful *compilers*, who will study old language, may inform the world that Robert earl of Oxford was high treasurer.

Swift.

In poetry they *compile* the praises of virtuous men and actions, and satires against vice. *Temple.*

COMPITALIA, or **COMPITALITA**, feasts held among the ancients in honor of the Lares; so called from *compitum*, a cross-way; because the feast was held in the meeting of several roads. The *compitalia* are more ancient than the building of Rome. Dionysius of Halicarnassus and Pliny indeed, say, they were instituted by Servius Tullus; but this only signifies that they were then introduced into Rome. The feast being movable, the day whereon it was to be observed was proclaimed every year. It was ordinarily held on the 4th of the nones of February. Macrobius observes, that they were held not only in honor of the Lares, but also of Mania, the goddess of madness. The priests who officiated at them were slaves and freed-men, and the sacrifice a sow. They were re-established after long neglect, by Tarquin II. on occasion of an answer of the oracle that they should sacrifice heads for heads; i. e. that for the health and prosperity of each family, children were to be sacrificed: but Brutus, after expelling the kings, in lieu of those barbarous victims substituted the heads of garlic and poppy; thus complying with the oracle by sacrificing heads. During the celebration of this feast, each family placed at the door of their house the statue of the goddess Minia. They also hung up at their doors figures of wood, representing men and women; accompanying them with supplications that the Lares and Mania would be contented with those figures, and spare the people of the house.

COMPLACENCE, *n. s.* } Lat. *complacens*;
COMPLACENCY, *n. s.* } low Lat. *complacencia*.
COMPLACENT, *adj.* } *centia*. Pleasure, gratification, more especially that which is derived from self approbation. The cause of pleasure; civility; complaisance; softness of manners; affability.

I by conversing cannot these erect
 From prone, nor in their way *complacence* find.

Milton.

O thou, in heaven and earth the only peace
 Found out for mankind under wrath! O thou,
 My sole *complacence*! *Id. Paradise Lost.*

When the supreme faculties move regularly, the inferior affections following, there arises a serenity and *complacency* upon the whole soul. *South.*

Complacency and truth, and manly sweetness,
 Dwell ever on his tongue, and smooth his thoughts

Addison.

With mean *complacence* ne'er betray your trust,
 Nor be so civil as to prove unjust. *Pope.*

COMPLAIN, *v. n. & a.* } Fr. *complaindre*,
COMPLAINANT, *n. s.* } *plainte*. To mention with sorrow and
COMPLAINER, *n. s.* } resentment; to murmur;
COMPLAIN'T, *n. s.* } to lament; to inform against.

A complainant is one who urges a suit, or commences a prosecution against another; a complainer is a murmurer, a lamenter; one who bewails or accuses. Complaint sometimes signifies the representation of what aggrieves; sometimes it is used for the cause of the evil, and not unfrequently for the evil itself.

And most of al, for this I me *complaine*,
 That she hath joy to laughen at my paine.

Chaucer. Complaint of the Black Knight.

Complaineth eke ye lovers al in fere,
For her that, with unfained humble chere,
Was ever redy to do you succour;
Complaineth hire that, er, hath be you dere;
Complaineth beaute, fredome and manere;
Complaineth hire that endeth your labour;
Complaineth thilke ensample of al honour,
That never dyd but gentilnesse;
Kytheth therefore in hire some kindenesse.

Chaucer. The Complaint of Mars.

I cannot find any cause of *complaint*, that good laws
have so much been wanting unto us, as we to them.

Hooker's Dedication.

Lord Hastings,
Humbly *complaining* to her deity,
Got my lord chamberlain his liberty.

Shakspeare. Richard III.

Now, master Shallow, you'll *complain* of me to the
council?
Id. Merry Wives of Windsor.

In evil straight this day I stand
Before my judge, either to undergo
Myself the total crime, or to accuse
My other self, the partner of my life;
Whose failing, while her faith to me remains,
I should conceal, and not expose to blame
By my *complaint*.

Milton.

How wisely nature did decree
With the same eyes to weep and see;
That having viewed the object vain,
They might be ready to *complain*.

Marvell.

For 't has been held by many that,
s Montaigne playing with his cat
Complains she thought him but an ass,
Much more she would Sir Hudibras.

Butler

Congreve and this author are the most eager *com-*
plainants of the dispute.
Collier's Defence.

Gaufride, who couldst so well in rhyme *complain*
The death of Richard, with an arrow slain.

Dryden's Fables.

Philips is a *complainer*; and on this occasion I told
lord Cartret, that *complainers* never succeed at court,
though railers do.
Swift.

The poverty of the clergy in England hath been the
complaint of all who wish well to the church.
Id.

To hear you prate would vex a saint;
Who have most reason of *complaint*?
Replies the cat.

Gay.

One, in a *complaint* of his bowels, was let blood till
he had scarce any left, and was perfectly cured.

Arbutnot.

But, if pity inspire thee, renew the sad lay;
Mourn, sweetest *complainer*, man calls thee to mourn;
O soothe him whose pleasures like thine pass away,
Full quickly they pass—but they never return.

Bcattie.

That I want nothing, said the prince, or that I
know not what I want, is the cause of my *complaint*;
if I had any known want I should have a certain
wish; that wish would excite endeavour, and I
should not then repine to see the sun move so slowly
towards the western mountains, or lament when the
day breaks and sleep will no longer hide me from
myself.
Johnson. Rasselas.

Loud *complaint*, however angrily

It shapes its phrase, is little to be feared,
And less distrusted.
Byron's Doge of Venice.

COMPLAISANCE, *n. s.* } Fr. *complaisance*,
COMPLAISANT, *adj.* } complaisant. Ci-
COMPLAISANTLY, *adv.* } vility; adulation;
COMPLAISANTNESS, *n. s.* } desire of pleasing,
with desire to please ceremoniously. Easy of
persuasion, bland, acquiescent.

Her death is but in *complaisance* to her. *Dryden*

Fair Venus wept the sad disaster
Of having lost her favorite dove:
In *complaisance* poor Cupid mourned;
His grief relieved his mother's pain.

Prior.

There are to whom my satire seems too bold;
Scarce to wise Peter *complaisant* enough,
And something said of Chartres much too rough.

Pope.

In plenty starving, tantalized in state,
And *complaisantly* helped to all I hate;
'reated, caressed, and tired, I take my leave.

Id.

COMPLA'NATE, *v. a.* } Lat. *planus*. To
COMPLA'NE. } level; to reduce to
a flat and even surface.

The vertebrae of the neck and back-bone are made
short and *complanated*, and firmly braced with muscles.
Derham.

COMPLE'AT. See COMPLETE.

COMPLEMENT, *n. s.* Lat. *complementum*.
Perfection; fulness; completion; complement.
Complete set; complete provision; the full
quantity or number. Adscititious circumstances;
appendages; parts not necessary, but ornament-
al: whence ceremony was called complement,
now corrupted to compliment.

Our custom is both to place it in the front of our
prayers as a guide, and to add it in the end of some
principal limbs or parts, as a *complement* which fully
perfecteth whatsoever may be defective in the rest.
Hooker.

They as they feasted had their fill,
For a full *complement* of all their ill. *Hubberd's Tale.*

The sensible nature, in its *complement* and integrity,
hath five exterior powers or faculties.

Hale's Origin of Mankind.

A doleful case desires a dolefull song,
Without vain art or curious *complements*;
And squalid fortune, into loseness flong,
Doth scorn the pride of wonted ornaments.

Spenser.

Garnished and decked in modest *compliment*,
Not working with the ear, but with the eye.

Shakspeare.

The god of love himself inhabits there,
With all his rage, and dread, and grief, and care;
His *complement* of stores, and total war.

Prior.

COMPLETE, *adj.* & *v. a.* } Lat. *completus*.
COMPLETELY, *adv.* } Perfect; full;
COMPLEMENT, *n. s.* } having no defi-
COMPLETENESS, *n. s.* } ciencies; having
COMPLETION, *n. s.* } no degrees, and
therefore not properly admitting more and most;
finished, ended, concluded.

With us the reading of scripture is a part of our
church liturgy, a special portion of the service which
we do to God; and not an exercise to spend the time,
when one doth wait for another coming, till the as-
sembly of them that shall afterwards worship him
be *complete*.
Hooker.

When I approach

Her loveliness, so absolute she seems
And in herself *complete*, so well to know
Her own, that what she wills to do or say,
Seems wisest, virtuousest, discreetest, best.

Milton's Paradise Lost.

Of a tall statue and of sable hue
Much like that son of Kish, that lofty Jew,
Twelve years *compleat* he suffered in exile,
And kept his father's asses all the while. *Marvell.*

Allow me to give you, from the best authors, the origin, the antiquity, the growth, the change, and the complement of satire among the Romans.

Dryden's Dedication to Juvenal.

This course of vanity almost complete,
Tired in the field of life, I hope retreat. *Prior.*

This was a full entire harmony and consent of all the divine predictions, receiving their completion in Christ. *South.*

Whatever person would aspire to be completely witty, smart, humorous, and polite, must be able to retain in his memory every single sentence contained in this work. *Swift.*

If any disposition should appear towards so good a work, the assistance of the legislative power would be necessary to make it more complete. *Id.*

To town he comes, completes the nation's hope,
And heads the bold trained-bands, and burns a pope. *Pope.*

He makes it the utmost completion of an ill character to bear a malevolence to the best men. *Id.*

The happy morn that shall her bliss complete,
And all her rivals' envious hopes defeat. *Gay.*

These parts go to make up the completeness of any subject. *Watts's Logick.*

That sabre's whirling sway,
Sheds fast atonement for its first delay;
Completes his fury, what their fear begun,
And makes the many basely quail to one. *Byron. Corsair.*

COMPLEX, *adj. & n. s.* } Lat. *complexus*.
COMPLEXED, *adj.* } Composite; of
COMPLEXEDNESS, *n. s.* } many parts; not
COMPLEXLY, *adv.* } simple; including
COMPLEXNESS, *n. s.* } many particulars.
COMPLEXURE, *n. s.* } Complication, in-
volvement of many particular parts in one integral.
The opposite of simplicity.

This parable of the wedding supper comprehends in it the whole *complex* of all the blessings and privileges exhibited by the gospel. *South's Sermons.*

Ideas made up of several simple ones, I call *complex*; such as beauty, gratitude, a man, the universe; which, though complicated of various simple ideas, or *complex* ideas made up of simple ones, yet are considered each by itself as one. *Locke.*

From the *complexedness* of these moral ideas, there follows another inconvenience, that the mind cannot easily retain those precise combinations. *Id.*

I know that all words which are signs of *complex* ideas, furnish matter of mistake and cavil. *Bolingbroke.*

With such perfection framed
Is this *complex* stupendous scheme of things. *Thomson's Spring.*

A secondary essential mode, called a property, sometimes goes toward making up the essence of a *complex* being. *Watts.*

COMPLEXION, *n. s.* } Latin, *complexio*.
COMPLEXIONAL, *adj.* } The enclosure or in-
COMPLEXIONALLY, *adv.* } volution of one thing
in another. The color of the external parts of
any body. The temperature of the body accord-
ing to the various proportions of the four medical
humors.

The sikenesse, or constellation,
Win, wo, or changing of *complexion*,
Causth ful oft to don amis or spoken;
On every wrong, a man may not be wrecen. *Chaucer. Cant. Tales.*

Amongst them all sate he which wonned there,

That hight Phantastes by his nature trew;
A man of yeares, yet fresh, as mote appere,
Of swarth *complexion* and of crabbed hew,
That him full of melancholy did shew. *Spenser.*
Men judge by the *complexion* of the sky
The state and inclination of the day *Shakspeare. Richard II.*

What see you in those papers, that you lose
So much *complexion*? *Id. Henry V.*

Men and other animals receive different tinctures from *complexional* effluences, and descend still lower as they partake of the fuliginous and denigrating humours. *Broune.*

An Indian king sent unto Alexander a fair woman, fed with poisons, either by converse or copulation *complexionally* to destroy him. *Id. Vulgar Errors.*

'Tis ill, though different your *complexions* are,
The family of heaven for men should war. *Dryden's Fables.*

The methods of providence, men of this *complexion* must be unfit for the contemplation of.

Burnet's Theory of the Earth.

Let melancholy rule supreme,
Choler preside, or blood, or phlegm,
It makes no difference in the case,
Nor is *complexion* honour's place. *Swift.*

If I write on a black man, I run over all the eminent persons of that *complexion*. *Addison's Spectator.*

Her wan *complexion*'s like the withered leek,
While Katherine pears adorn my ruddy cheek. *Gay.*

Though the terms of proposition may be *complex*, yet where the composition of the argument is plain, simple, and regular, it is properly called a simple syllogism, since the *complexion* does not belong to the syllogistick form of it. *Watts.*

COMPLEXION. Few questions in philosophy have engaged the attention of naturalists more than the diversities of the human species, among which that of color is the most remarkable. The great differences in this respect have given occasion to several authors to assert, that the whole human race have not sprung from one original; but that as many different species of men were at first created, as there are now different colors to be found. It appears, indeed, a matter of no small difficulty to account for the remarkable variations of color that are to be found among different nations. On this subject Dr. Hunter published a thesis, in which he determined absolutely against any specific difference among mankind. He commences with a definition of the term species including all those animals under the same species, which produce issue capable of propagating others resembling the original stock. As in the case of plants, one species comprehends several varieties depending upon climate, soil, culture, and similar accidents; so he considers the diversities of the human race to be merely varieties of the same species, produced by natural causes, and gives the following view of the different colors observable among mankind: I. Black: 1. Africans under the line; 2. Inhabitants of New Guinea; 3. Inhabitants of New Holland. II. Swarthy: 1. The Moors in the Northern parts of Africa; 2. The Hottentots on the Southern parts of it. III. Copper-colored: The East Indians. IV. Red: The Americans. V. Brown: 1. Tartars; 2. Persians; 3. Arabs;

4. Africans on the coast of the Mediterranean; 5. Chinese. VI. Brownish: The inhabitants of the southern parts of Europe; as 1. Sicilians; 2. Spaniards; and 3. Turks; also 4. Samoiedes; 5. Laplanders; 6. Abyssinians. VII. White: Most of the other European nations, as, 1. Swedes; 2. Danes; 3. Britons; 4. Germans; 5. Poles, &c.; 6. Kabardinski; 7. Georgians; 8. Inhabitants of the islands of the Pacific Ocean. The doctor thinks there can be no dispute as to the seat of color being placed in the skin; that it is not even extended over the whole of this, but confined to that part named the cuticle, consisting of the epidermis and reticulum; and that it chiefly occupies the latter of these.

The cuticle is much thicker and harder in black people, he observes, than in white ones; the reticulum in the latter being a thin mucus, in the form of a thick membrane. He concludes that this seat of color in whites is transparent, and either totally deprived of vessels, or furnished with very few; as the yellow color appearing in jaundice vanishes on the cause of the disease being removed; which is not the case with stains in the cuticle from gunpowder, or similar causes. He next points out three causes, destroying the pellucidity of the cuticle, giving it a brown color, and rendering it thicker. These are, access of air, filthy habits, and the heat of the sun. The influence of each of these he proves by many examples; and considers the last as by much the most powerful. Hence, he accounts for all the diversity of color observed among mankind.

This subject has been further illustrated by Mr. Clarkson, in a dissertation introduced into his *Essay on the Commerce and Slavery of the Human Species*. The old anatomists, he observes, usually divided the skin into two parts or laminae; the exterior and thinnest, called by the Greeks epidermis, by the Romans cuticula, and hence by us cuticle; and the interior, called by the former derma, and by the latter cutis, or true skin.

Malpighi, an eminent Italian physician of the last century, was the first that discovered that the skin was divided into three laminae; the cuticle, the true skin, and a certain coagulated substance, situated between both, which he distinguished by the title of rete mucosum, and which adhered so firmly to the cuticle, as, in all former anatomical preparations, to have come off with it; which led the ancient anatomists to believe, that there were but two divisible portions in the human skin. This discovery was sufficient to ascertain the point in question; for it appeared afterwards that the cuticle, when divided according to this discovery from the other lamina, was semi-transparent; that the cuticle of the blackest negro was of the same transparency and color as that of the purest white; and hence, the true skins of both being invariably the same, that the rete mucosum was the seat of color. This has been farther confirmed by all subsequent anatomical experiments; by which it appears, that, whatever be the color of this coagulated substance, nearly the same is the apparent color of the upper surface of the skin. The transparency of the cuticle is a matter of ocular demonstration in white people. It is conspicuous in every blush; for no one

can imagine, that the cuticle becomes red as often as this happens; nor is it less discoverable in the veins, which are so easy to be discerned; for no one can suppose that the blue streaks, which he constantly sees in the fairest complexions, are painted, as it were, on the surface of the upper skin. From these, and other observations, no maxim is more true in physiology, than that the rete mucosum, being of a different color in different inhabitants of the globe, and appearing through the cuticle or upper surface of the skin, gives them that various appearance which strikes us so forcibly in contemplating the human race. Whatever causes, therefore, co-operate in producing this different appearance, they produce it by acting upon the rete mucosum; which, from the almost incredible manner in which the cuticle is perforated, is as accessible as the cuticle itself. These causes are probably those various qualities of things, which, combined with the influence of the sun, contribute to form what we call climate. For whoever considers, that the mucous substance is found to vary in its color, as the climates vary from the equator to the poles, must be instantly struck with the analogy, and conclude the mucous substance to be the genuine cause of the phenomenon. The natives of many places in Asia are found to have their rete mucosum black; those of Africa, situated near the line, of the same color; those of the maritime parts of the same continent, of a dusky brown, nearly approaching to it; and the color becomes lighter or darker, in proportion as the distance from the equator is greater or less.

The only objection of any consequence that has ever been made to the hypothesis of climate, is this, that people under the same parallels are not of the same color. But it does not follow that those countries which are at an equal distance from the equator, should have their climates the same. Indeed nothing is more contrary to experience. Climate depends upon a variety of accidents. High mountains in the neighbourhood of a place make it cooler, by chilling the air that is carried over them by the winds. Large spreading succulent plants have the same effect; they afford agreeable cooling shades, and a moist atmosphere from their continual exhalations, by which the ardor of the sun is much abated. On the other hand, soil of a sandy nature retains the heat in an uncommon degree, and makes the summers considerably hotter than those which exist in the same latitude where the soil is different. To the proximity of burning sands, and and to the sulphurous and metallic particles continually exhaling from the earth, is, therefore, to be ascribed the different degrees of blackness by which some African nations are distinguishable from others, though under the same parallels. To the preceding arguments, may be added one that seems incontrovertible, viz. that when the black inhabitants of Africa are transplanted to colder, or the white inhabitants of Europe to hotter climates, their children are of a different color from themselves; that is, lighter in the first, and darker in the second instance. See our article CLIMATE.

This doctrine is adopted by professor Zimmerman of Brunswick, in his celebrated work, *The*

Geographical History of Man, &c. who confirms it by observing, that the mountaineers of warm climates, as in Barbary and Ceylon, are much fairer than the inhabitants of the valleys: that the Saracens and Moors, who conquered the north-east part of Africa, from being brown, are become like the negroes near the equator; that the Portuguese who settled at Senegal in 1400, became blacks; and the Jews in Abyssinia of the dark complexion of the original natives.

Upon the whole, color and figure may be styled habits of the body; created, not by great and sudden impressions, but by continual and almost imperceptible touches. Of habits, both of mind and body, nations are susceptible as well as individuals. They are transmitted to offspring and augmented by inheritance. Long in growing to maturity, national features, like national manners, become fixed only after a succession of ages. They become, however, fixed at last; and if we can ascertain any effect produced by a given state of weather or of climate, it requires only repetition, during a sufficient length of time, to augment and impress it with a permanent character. The sanguine countenance will, for this reason, be perpetual in the highest latitudes of the temperate zone; and we shall always find the swarthy, the olive, the tawny, and the black, as we descend to the south. The uniformity of the effect in the same climate, and on men in a similar state of society, proves the power and certainty of the cause. The foregoing observations are excellently illustrated by new facts, and enforced by additional reasoning, founded on considerable personal investigation of facts, by Dr. Samuel Stanhope Smith, professor of moral philosophy in New Jersey, in his Essay on the Causes of the Variety of Complexion and Figure in the Human Species; to which we refer the reader.

COMPLICATE, *v. a. & adj.* } Lat. *compli-*
COMPLICATENESS, *n. s.* } *co.* To entan-
COMPLICATION, *n. s.* } gle one with
another; to join; to involve mutually. To unite
by involution of parts one in another. To form
by the union of several parts into one.

Though the particular actions of war are *complicate* in fact, yet they are separate and distinct in right.

Bacon.

Dreadful was the din
Of hissing through the hall! thick swarming now
With *complicated* monsters, head and tail.

Milton's *Paradise Lost*.

There is a great variety of intelligibles in the world, so much objected to our senses, and every several object is full of subdivided multiplicity and *complicatedness*.

Hale's *O'igin of Mankind*.

Commotion in the parts may make them apply themselves one to another, or *complicate* and dispose them after the manner requisite to make them stick.

Boyle's *History of Firmness*.

The notions of a confused knowledge are always full of perplexity and *complications*, and seldom in order.

Wilkins.

In case our offence against God hath been *complicated* with injury to men, we should make restitution.

Tillotson.

Attachment to a private person must comprehend a great concern for his character and his interest; but

attachment to one who is or may be a king, much more; because the character of the latter is more important to himself and others; and because his interests are vastly more *complicated* with those of his country, and in some sort with those of mankind.

Bolingbroke.

When the disease is *complicated* with other diseases, one must consider that which is most dangerous.

Arbuthnot on *Diet*.

What pleasure would felicitate his spirit if he could grasp all in a survey, as a painter runs over a *complicated* piece wrought by Titian or Raphael.

Watts on the *Mind*.

By admitting a *complication* of ideas, and taking too many things at once into one question, the mind is dazzled and bewildered.

Watts's *Logic*.

COMPLICE, *n. s.* French, from low Lat. *compler*, an associate. One who is united with others in an ill design; an associate; a confederate; an accomplice.

To arms, victorious noble father,

To quell the rebels and their *complices*.

Shakspeare. *Henry VI.*

Justice was afterwards done upon the offenders, the principal being hanged and quartered in Smithfield; and divers of his chief *complices* executed in divers parts of the realm.

Hayward.

The marquis prevailed with the king, that he might only turn his brother out of the garrison, after justice was done upon his *complices*.

Clarendon.

COMPLIMENT, *n. s., v. a., & n.* } Fr. *compli-*
COMPLIMENTAL, *adj.* } *ment.* An
COMPLIMENTALLY, *adv.* } act of ex-
COMPLIMENTER, *n. s.* } pression of
civility, usually understood to include some hypocrisy, and to mean less than it declares: this is properly complement, something superfluous, or more than enough. See COMPLEMENT.

What honour that,

But tedious waste of time, to sit and hear

So many hollow *compliments* and lyes,

Outlandish flatteries?

Milton's *Paradise Regained*.

The watchman gave so very great a thump at my door, that I awaked, and heard myself *complimented* with the usual salutation.

Tatler.

She *compliments* Menelaus very handsomely, and says he wanted no accomplishment either of mind or body.

Pope.

This falsehood of Ulysses is intirely *complimental* and officious.

Broome.

This speech has been condemned as avaricious: Eustathius judges it spoken artfully and *complimentally*.

Id.

Many women doat upon a man for his *complement* only, and good behaviour: they are won in an instant.

Burton's *Anatomy of Melancholy*.

Churlish despite ne'er looked from his calm eye,
Much less commanded in his gentle heart:

To basest men fair looks he would impart;

No could he cloak ill thoughts in *complimental* art.

Fletcher's *Purple Island*.

How did you praise my shape and graceful air!
And woman thinks all *compliments* sincere.

Gay.

The brief proclaimed, it visits every pew,
But first the squire's, a *compliment* but due:

With slow deliberation he unties

His glittering purse, the envy of all eyes.

Cowper.

COMPLINE, *n. s.* Fr. *compline*; low Lat. *completinum*. The last act of worship at night, by which the service of the day is completed.

At morn and eve, besides their anthems sweet,
Their penny masses, and their *complines* meet.

Hubberd's Tale.

If a man were but of a day's life, it is well if he
lasts till even-song, and then says his *compline* an
hour before the time.

Taylor's Holy Living.

COMPLÔRE, *v. n.* Lat. *comploro*. To
make lamentation together.

COMPLOT, *n. s. & v. a.* } Fr. from *com-*

COMPLÔTER, *n. s.* } *pletum*, for *com-*
pletum, low Lat. *Menage*. A confederacy in
some secret crime; a plot; a conspiracy. To
form a plot; to conspire; to join in any secret
design, generally criminal.

I cannot, my life, my brother, like but well
The purpose of the *complot* which ye tell.

Hubberd's Tale.

I knew their *complot* is to have my life.

Shakspeare. Henry VI.

Jocasta too, no longer now my sister,
Is found *complotter* in the horrid deed.

Dryden and Lee's Oedipus.

A few lines after, we find them *complotting* together,
and contriving a new scene of miseries to the Trojans.

Pope.

COMPLUTENSIAN POLYGLOTT, so called
from Complutum, the Latin name of Alcalá,
in Spain, was the first polyglott ever published.
It was the work of cardinal Ximenes, and was
completed in 6 vols. folio. See BIBLE and
ALCALÁ.

COMPLY, *v. n.* }

COMPLI'ANT, *n. s.* } Skinner derives it from
COMPLI'ANT, *adj.* } the Fr. *complaire*; but
COMPLI'ER, *n. s.* } probably it comes from
complier to bend to.

Plier is still in use. To yield to; to be obsequious to; to accord with; to suit with. It has
with before as well persons as things.

The *compliant* boughs

Yielded them. *Milton's Paradise Lost.*

The rising sun *complies* with our weak sight,
First gilds the clouds, then shows his robe of light.

Waller.

He was a man of few words, and of great *compliance*;
and usually delivered that as his opinion,
which he foresaw would be grateful to the king.

Clarendon.

We are free from any necessary determination of
our will to any particular action, and from a necessary
compliance with our desire, set upon any particular,
and then appearing preferable, good.

Locke.

Remember I am she who saved your life,
Your loving, lawful, and *complying* wife. *Dryden.*

He made his wish with his estate *comply*;
Joyful to live, yet not afraid to die. *Prior.*

What *compliances* will remove dissension, while the
liberty continues of professing what new opinions we
please? *Swift.*

Suppose a hundred new employments were erected
on purpose to gratify *compliers*, an insupportable diffi-
culty would remain. *Id.*

Nothing can save him but divorce,

And here the wife *complies* of course. *Gay.*

He came early and departed late; laboured to re-
commend himself by assiduity and *compliance*; excited
their curiosity after new arts, that they might still
want his assistance; and when they made any ex-
cursion of pleasure or enquiry, entertained to attend
them. *Johnson's Rasselas.*

COMPONE, COMPONED, or GOBONY, in her-
aldry. A bordure compone is that formed or
composed of a row of angular parts, or chequers
of two colors.

COMPONED, or COMPOSED, is
also used in general for a bor-
dure, a pale, or a fess, composed
of two different colors or metals
disposed alternately, separated
and divided by fillets, as in the
diagram annexed.

COMPONENT, *adj.* Lat. *componens*. That
which constitutes a compound body.

The bigness of the *component* parts of natural
bodies may be conjectured by their colours.

Newton's Opticks.

COMPORT, *v. n., v. a. & n. s.* } Fr. *compor-*

COMPORTABLE, *adj.* } *ter*; from La-

COMPORTANCE, *n. s.* } *tin porto*. To

COMPORTMENT, *n. s.* } *agrec*; to suit;

to behave; to carry; with the reciprocal pro-

nomoun. Consistent, as opposed to contradictory

behaviour; gesture of ceremony; conduct.

Some piety's not good there, some vain disport

On this side sin, with that place may *comport*. *Donne.*

So beene they both atone, and doen

Their bevers bright each other for to greet,

Goodly *comportance* each to other beare,

And entertaine themselves with court'sies meet.

Spenser.

At years of discretion, and *comport* yourself at
this rantpole rate! *Congreve's Way of the World.*

I shall account concerning the rules and manners
of deportment in the receiving, our *comport* and con-
versation in and after it.

Taylor's Worthy Communicant.

Children in the things they do, if they *comport* with
their age, find little difference, so they may be doing

Locke.

We cast the rules and cautions of this art into some
comportable method. *Wotton's Architecture.*

By her serious and devout *comportment* on these so-
lemn occasions, she gives an example that is very
often too much wanted. *Addison's Freeholder.*

COMPOSE, *v. a.* } Fr. *composer*; Lat

COMPOSED, *part. adj.* } *compono*. To form a

COMPOSEDLY, *adv.* } mass by joining differ-

COMPOSEDNESS, *n. s.* } ent things together,

COMPOSER, *n. s.* } to place anything in

COMPO'SITIVE, *adj.* } its proper form and

COMPO'SITOR, *n. s.* } method; to put in the

COMPO'SURE, *n. s.* } proper state for any

purpose; to put together a discourse or sentence;
to constitute by being parts of a whole—to calm;
to quiet, to adjust, and tranquilise the mind.

Words so pleasing to God, as those which the Son
of God himself hath *composed*, were not possible for
men to frame. *Hooker.*

Nor did Israel 'scape

The' infection, when their borrowed gold *composed*

The calf in Oreb. *Milton's Paradise Lost.*

Now will be the right season of forming them to be
able writers and *composers* in every excellent matter.

Milton.

Flowers dress the altars for the cloaths

The sea-born amber we *compose*. *Marvell.*

He would undertake the journey with him, by which
all his fears would be *composed*. *Clarendon.*

The whole army seemed well *composed* to obtain that by their swords which they could not by their pen. *Clarendon.*

A man was walking before the door very *composedly* without a hat. One crying, Here is the fellow that killed the duke; every body asked, which is he? The man without the hat very *composedly* answered, I am he. *Id.*

Zeal ought to be *composed* of the highest degrees of all pious affections. *Spratt.*

The *composer* has so expressed my sense, where I intended to move the passions, that he seems to have been the poet as well as the *composer*.

Dryden's Albion and Albanus, Preface.

Compose thy mind;

Nor frauds are here contrived, nor force designed. *Dryden.*

Yet, to *compose* this midnight noise,

Go freely search where'er you please. *Prior.*

How doth the sea exactly *compose* itself to a level superficies, and with the earth make up one spherical roundness. *Ray.*

The Mantuan there in sober triumph sate,

Composed his posture, and his look sedate. *Pope.*

Ye murmuring streams that in meanders roll,

The sweet *composer* of the pensive soul

Farewell. *Gay.*

Discourses on such occasions are seldom the productions of leisure, and should be read with those favourable allowances that are made to hasty *composures*. *Atterbury.*

The style of Georgias of Leontium was formed into short sentences, *composed* generally of two members balanced against each other. The style of Isocrates, on the contrary, is swelling and full; and he is said to be the first who introduced the method of *composing* in regular periods which had a studied music and harmonious cadence. *Gibbon.*

Of jarring elements *composed* the noise,

When Chaos from his old dominion torn,

With all his bellowing throng,

Far, far was hurled, the void abyss along. *Beattie.*

COMPOSING STICK, an instrument used in printing, which, from its name, appears to have been originally made of wood, but has long been made of brass or iron. See **PRINTING**.

COMPOSITE. See **BOTANY**.

COMPOSITE, *adj.* Lat. *compositus*.

The *composite* order in architecture is the last of the five orders of columns; so named, because its capital is composed out of those of the other orders; and it is also called the Roman and Italic order. *Harris.*

Some are of opinion that the *composite* pillars of this arch were in imitation of the pillars of Solomon's temple. *Addison.*

COMPOSITE NUMBERS are such as can be measured exactly by a number exceeding unity; as 6 by 2 or 3, or 10 by 5, &c., so that 4 is the lowest composite number. Composite numbers, between themselves, are those which have some common measure besides unity; as 12 and 15, as being both measured by 3.

COMPOSITE ORDER. See **ARCHITECTURE**.

COMPOSITION, *n. s.* Lat. *compositio*. The act of forming an integral of various dissimilar arts; a mass formed by mingling different ingredients; the act of bringing simple ideas into complication: opposed to analysis, or the separation of complex notions; the arrangement of various figures in a picture; the act of discharg-

ing a debt by paying part; the sum paid; written work; adjustment; regulation; the state of being compounded; union; conjunction; combination; consistency; congruity; compact; agreement; terms on which differences are settled.

To take away all such mutual grievances, injuries, and wrongs, there was no way but only by going upon *composition* and agreement amongst themselves. And again, all publick regiment, of what kind soever, seemeth evidently to have arisen from deliberate advice, consultation, and *composition* between men, judging it convenient and behoveful. *Hooker.*

There is no *composition* in these news,

That gives them credit. _____

—Indeed they are disproportioned.

Shakspeare. Othello.

A preacher, in the invention of matter, election of words, *composition* of gesture, look, pronunciation, motion, useth all these faculties at once.

Ben Jouson's Discoveries.

The disposition in a picture is an assembling of many parts; is also called the *composition*, by which is meant the distribution and orderly placing of things, both in general and in particular. *Dryden's Dufresney.*

The investigation of difficult things, by the method of analysis, ought ever to precede the method of *composition*. *Newton's Opticks.*

In the time of the Yncas reign of Peru, no *composition* was allowed by the laws to be used in point of medicine, but only simples proper to each disease. *Temple.*

When I read rules of criticism, I enquire after the works of the author, and by that means discover what he likes in a *composition*. *Addison's Guardian.*

Love mixed up all, and his best clay employed,
Then called the happy *composition* Floyd. *Swift.*

Contemplate things first in their own simple natures, and afterwards view them in *composition* with other things. *Watts.*

COMPOSITION, in commerce, a sum of money in part payment of a debt, which the creditors accept in liquidation of the whole, and for which they give a general acquittance to the debtor.

COMPOSITION, in literature, the art of forming and arranging sentiments, and clothing them with language suitable to the nature of the subject.

COMPOSITION, in logic, a method of reasoning, whereby we proceed from some general self-evident truth to other particular and singular ones. In arranging our thoughts, there are two ways of proceeding equally within our choice: for we may suppose the truths, relating to any part of knowledge, as they presented themselves to the mind in the manner of investigation; carrying on the series of proofs in a reverse order, till they at last terminate in first principles; or, beginning with these principles, we may take the contrary way; and from them deduce, by a direct train of reasoning, all the several propositions we want to establish. This diversity in the manner of arranging our thoughts gives rise to the two-fold division of method established among logicians, called analytic and synthetic.

COMPOSITION, in music, is the art of inventing and writing airs; of accompanying them with a suitable harmony; and forming a complete piece of music in all its parts.

COMPOSITION, in music, is also applied to such pieces as are formed according to the rules of the art. Hence duettos, trios, quartetos, &c. are called compositions.

COMPOSITION, or COMPOSING, in printing, the arranging of several types or letters in the composing stick in order to form a line; and of several lines ranged in order, in the galley, to make a page; and of several pages to make a form. See PRINTING.

COMPOST, *n. s.* & *v. a.* } Lat. *compositum*.
Composture, n. s. } A mixture of various substances for enriching the ground; manure; to manure; to enrich with soil.

The earth's a thief,

That feeds and breeds by a *composture* stolen
 From general excrements. *Shakspeare. Timon.*

By removing into worse earth, or forbearing to *compost* the earth, water-mint turneth into field-mint, and the colewort into rape. *Bacon's Natural History.*

As for earth, it *composteth* itself; for I knew a garden that had a field poured upon it, and it did bear fruit excellently. *Id.*

There, as his dream foretold, a cart he found,
 That carried *compost* forth to dung the ground.

Dryden.

In vain the nursling grove
 Seems fair awhile, cherished with foster earth;
 But when the alien *compost* is exhaust,
 Its native poverty again prevails. *Philips.*

COMPOST, in agriculture, a mixture of manure. An oil compost is recommended in the Geographical Essays, upon a supposition that the food of vegetables is of an oily nature. It is made as follows: Take of North American potassa 12 lbs. Break the salt into small pieces, and put it into a convenient vessel with four gallons of water. Let the mixture stand forty-eight hours; then add of coarse train oil fourteen gallons. In a few days the salt will be dissolved, and the mixture, upon stirring, will become nearly uniform. Take fourteen bushels of sand, or twenty of dry mould; upon these pour the above liquid ingredients. Turn this compost frequently over, and in six months it will be fit for use. When the liquid ingredients are put to one or two hogsheds of water a liquid compost will be formed, which must be used with a water cart. This compost, however, the inventor himself owns to be inferior to rotten dung.

On the supposition that vegetables are supported by matters of a saline nature, composts formed of different sorts of salts have been contrived, but with little success. A famous composition of this kind was once sold by patent, under the name of Baron Van Haaak's compost; but the Geographical Essays report it as a very poor one. The crop could not have been worse had it been left destitute of every assistance. Composts, made with putrefied animal substances, answer much better, in most cases, than any other kind of manure, but they are difficult to be procured. The following is recommended by Dr. Hunter of York. 'Take a sufficient quantity of saw-dust, incorporate it with the blood and offal of a slaughter-house, putting a layer of one and a layer of the other till the whole becomes a moist and fetid composition. Two loads of this compost, mixed

with three loads of earth will be sufficient for an acre of wheat or spring cotton. Being a kind of top dressing, it should be put on at the time of sowing, and harrowed in with the grain. As this kind of compost lies in a small compass, it seems well adapted for the use of those farmers who are obliged to bring their manures from a distance. It is besides extremely rich, and will probably continue in the land much longer than fold-yard or stable dung. I apprehend that it is capable of restoring worn out land to its original freshness; and I am induced to be of that opinion from the appearance of the crop now growing upon land much impoverished by bad management. Mixing dung in a state of fermentation with peat, says Mr. Loudon, or forming what in Scotland are called meadow-bank middens is a successful mode of increasing the quantity of putrescent manure. The peat being dug and partially dried may either be carted into the farm-yard and spread over the cattle court, there to remain till the whole is carted out and laid upon a dunghill to ferment; or it may be mixed up with the farm-yard dung as carted out. If care be taken to watch the fermenting process, as the fire of a clay kiln is watched, a few loads of dung may be made to rot many loads of peat.

COMPOSTELLA, or ST. IAGO DE COMPOSTELLA, a considerable town of Spain, the capital of Galicia, with an archbishop's see, and a university founded in 1532. It was the Brigantium of the ancients. The public squares, and the churches, particularly the metropolitan, are magnificent, and it has a great number of monasteries for both sexes. It is pretended that the body of St. James was buried here; and pilgrims still walk in procession to the church, and visit a wooden image of the saint. The archbishop is one of the richest prelates in Spain. This town is the seat of the military order of St. Jago, or St. James, having eighty-seven commanderies, and a revenue, it is said, of 200,000 golden ducats. Some trade is carried on 'n wine, fruit, and fish; and manufactures of silk-stockings, hats, paper, and leather. Population about 12,000. It is seated on a peninsula, formed by the rivers Tambre and Ulla, 270 miles north-west of Madrid.

COMPOSTELLA, NEW, a rich town of Mexico in the province of Xalisco, and intendency of Guadaluaxara, built in 1331. It is situated near the South Sea, 400 miles north-west of Mexico. The soil is barren and the air unhealthy; but there are several mines of silver at St. Pecaque, and some excellent tobacco in its neighbourhood.

COMPOTATION, *n. s.* Lat. *compotatio*. The act of drinking or tipping together.

Secrecy to words spoke under the rose, only mean,
 in *compotation*, from the ancient custom in symposiack meetings, to wear chaplets of roses

Browne's Vulgar Errors.

If thou wilt prolong
 Dire *compotation*, forthwith reason quits
 Her empire to confusion and misrule,
 And vain debates; then twenty tongues at once
 Conspire in senseless jargon; nought is heard
 But din and various clamour, and mad rant.

Philips

COMPOUND, *v. a., v. n., adj. & n. s.* } Lat.
 COMPOUNDABLE, *adj.* } *compo-*
 COMPOUNDER, *n. s.* } *no.* To

mingle many ingredients together in one mass; to form by uniting various parts; to mingle in different positions; to combine; to adjust a difference by some recession from the rigor of claims; to discharge a debt by paying only part. To bargain in the lump; to come to terms by granting something on each side.

Here what? quod I, 'the grete sowne
 (Quod he) 'that rombleth up and downe,
 In Fame's House, full of tidings,
 Botho of faire speche and of chidings,
 And of false and sothe, *compounded.*
 Herken wel; it is not rowned.

Chaucer's House of Fame.

Therefore, conspiring all together plaine,
 They did their counsels now in one *compound*,
 Where singled forces faile, conioynd may gaine.
 The Platant Beast, the fittest meanes they found
 To work his utter shame, and thoroughly him con-
 found. *Spenser.*

I would to God all strifes were well *compounded!*
Shakspeare.

Here 's a fellow will help you to-morrow; *compound*
 with him by the year. *Id. Measure for Measure.*

If there be any discord or suits between any of the
 family, they are *compounded* and appeased.

Bacon's New Atlantis.

Where it and Tigris embrace each other under the
 city of Apamia, there do they agree of a joint and
compounded name, and are called Pisis-Tigris.

Raleigh's History of the World.

O then let me in time *compound*
 And parley with those conquering eyes,
 Ere they have tryed the force to wound,
 Ere with their glancing wheels they drive
 In triumph over hearts that strive,
 And them that yield but more d'spise. *Marvell.*

They were, at last, glad to *compound* for his bare
 commitment to the Tower. *Clarendon.*

Pray but for half the virtues of this wife;
Compound for all the rest, with longer life. *Dryden.*

But useless all, when he despairing found
 Catullus then did with the winds *compound*.
Id. Juvenal.

The ideas, being each but one single perception,
 are easier got than the more complex ones; and
 therefore are not liable to the uncertainty which at-
 tends those *compound* ones. *Locke.*

Love why none one passion call,
 When 'tis a *compound* of them all;
 Where hot and cold, where sharp and sweet,
 In all their equipages meet. *Swift.*

Those softners, sweetners, *compounders*, and ex-
 pedient-mongers, who shake their heads so strongly.
Id.

We cannot have a single image that did not enter
 through the sight; but we have the power of altering
 and *compounding* those images into all the varieties
 of picture. *Addison's Spectator.*

Those who are his greatest admirers, seem pleased
 with them as beauties; I speak of his *compound* epi-
 thets. *Pope.*

Shall I, ye gods! he cries, my debts *compound?*
Gay.

Compound substances are made up of two or mor-
 e simple substances. *Watts's Logick.*

The value of any object that supplies the wants or
 pleasures of mankind, is *compounded* of its substance
 and its form, of the materials and its manufacture.

Gibbon.

COMPOUND INTEREST, interest upon interest, is
 that which is reckoned not only upon the princi-
 pal, but upon the interest itself; which hereby
 becomes a sort of additional principal. See
 INTEREST.

COMPOUND NUMBERS, those which can be
 divided by some other number besides unity,
 without leaving any remainder; such are 18, 20,
 &c. the first being measured by the numbers 2,
 6, or 9; and the second by the numbers 2, 4,
 5, 10.

COMPREHEND, *v. a.* } Lat. *compre-*
 COMPREHENSIBLE, *adj.* } *hendo, compre-*
 COMPREHENSIBLY, *adv.* } *hensibilis; Fr.*
 COMPREHENSION, *n. s.* } *comprehensibilis;*
 COMPREHENSIVE, *adj.* } Lat. *comprehen-*
 COMPREHENSIVELY, *adv.* } *sio. To com-*
 COMPREHENSIVENESS, *n. s.* } *prise; to in-*

clude; to contain; to imply. It applies particu-
 larly to the mind; thus too it signifies
 intelligible; conceivable by the understanding.
 The power of the mind to admit and contain
 many ideas at once. The noun is used in the
 sense of summary; epitome; compendium; ab-
 stract; abridgement, in which much is comprised.
 In rhetoric it is a trope or figure by which the
 name of a whole is put for a part, or that of a
 part for the whole, or a definite number for an
 indefinite.

'Sir!' quod he, 'sihens firste Frouthe
 Have any maner witte fro youthe,
 Or kindly understandinge
 To *comprende* in any thinge
 What love was in mine owne wit.

Chaucer's Tote of the Duchesse.

Rome was not better by her Horace taught,
 Than we are here to *comprende* his thought. *Waller.*

In the Old Testament there is a close *comprehension*
 of the New, in the New an open discovery of the
 Old. *Hooker.*

Lest this part of knowledge should seem to any
 not *comprehensible* by axiom, we will set down some
 heads of it. *Bacon.*

It would be ridiculous to grow old in the study of
 every necessary thing, in an art which *comprehends* so
 many several parts. *Dryden's Dufresnoy.*

No other fear himself could *comprende*,
 Than lest heaven fall ere thither he ascend. *Marvell.*

You gentle shepherds, and you snowy sires,
 That sit around, my rugged rhymes attending;
 How may I hope to quit your strong desires,
 In verse uncouth, such wonders *comprehending*.
Fletcher's Purple Island.

So diffusive, so *comprehensive*, so catholic a grace is
 charity, that whatever time is the opportunity of any
 other virtue, that time is the opportunity of charity.

Syratt's Sermons.

You give no proof of decay of your judgment, and
comprehension of all things, within the compass of an
 human understanding. *Dryden.*

The horizon sets the bounds between the enlight-
 ened and dark parts of things, between what is and
 what is not *comprehensible* by us. *Locke.*

His hand untaimed, his uncorrupted heart,
His *comprehensive* head; all interests weigh'd,
All Europe saved, yet Britain not betray'd.

Pope's Epistles.

Compare the beauty and *comprehensiveness* of legends on ancient coins. *Addison on Ancient Medals.*

As when some skilful cook to please each guest,
Would in one mixture *comprehend* a feast,
With due proportion and judicious care,
He fills his dish with different sorts of fare,
Fishes and fowls deliciously unite
To feast at once the taste, the smell, and sight. *Gay.*
'Tis he alone, whose *comprehensive* mind,
From situation, temper, soil, and clime,
Explored a nation's various powers can bind,
And various orders in one form sublime
Of policy. *Beattie.*

Then farewell Horace; whom I hated so,
Not for thy faults but mine; it is a curse
To understand, not feel thy lyric flow,
To *comprehend*, but never love thy verse.

Byron. Child Harold.

COMPREHENSION, in English church history, denotes a scheme proposed by Sir Orlando Bridgman in 1667-8, for relaxing the terms of conformity in behalf of Protestant Dissenters, and admitting them into the communion of the church. A bill for this purpose was drawn up by lord chief baron Hale, but disallowed. The attempt was renewed by Tillotson and Stillingfleet in 1674, and the terms were settled to the satisfaction of the non-conformists; but the bishops refused their assent. This scheme was likewise revived again immediately after the Revolution; the king and queen expressed their desire of an union; however the design failed after two attempts, and the act of toleration was obtained.

COMPREHENSION, in metaphysics, is that act of the mind whereby it comprehends or knows any object that is presented to it on all the sides on which it is capable of being apprehended or known.

COMPRESS, <i>v. a. & n. s.</i>	} Lat. <i>compressus</i> , <i>compressio</i> . To force into a nar- rower compass; to squeeze toge- ther. To embrace.
COMPRESSIBILITY, <i>n. s.</i>	
COMPRESSIBLE, <i>adj.</i>	
COMPRESSIBLENESS, <i>n. s.</i>	
COMPRESSSION, <i>n. s.</i>	
COMPRESSURE, <i>n. s.</i>	

Compressibility is the quality of being compressible; the quality of admitting to be brought by force into a narrow compass; as air may be compressed, but water can by no violence be reduced to less space than it naturally occupies; and compression is the act of bringing the parts of any body more near to each other by violence; the quality of admitting such an effect of force as may compel the body compressed into a narrower space.

Whenever a solid body is pressed, there is an inward tumult in the parts, seeking to deliver themselves from the *compression*; and this is the cause of all violent motion. *Bacon.*

Tears are the effects of the *compression* of the moisture of the brain, upon dilatation of the spirits.

Bacon's Natural History.

There being spiral particles, accounts for the elasticity of air; there being spherical particles, which give free passage to any heterogeneous matter, accounts for air's being *compressible*.

Cheyne's Philosophical Principles.

We tried whether heat would, notwithstanding so forcible a *compression*, dilate it.

Boyle's Spring of the Air.

Her Neptune eyed, with bloom of beauty blest,
And in his cave the yielding nymph *compress*.
Pope's Odyssey.

There was in the island of Io, a young girl *compressed* by a genius, who delighted to associate with the muses. *Pope.*

COMPRIANT, *v. n.* Lat. *comprimere*. To print together; it is commonly taken, in law, for the deceitful printing of another's copy, or book, to the prejudice of the rightful proprietor.

COMPRISE, *v. a.* Fr. *comprendre*, *compris*. To contain; to comprehend; to include.

Rome was the whole world, and all the world was Rome,
And if things named their names doo equalize,
When land and sea ye name, then name ye Rome;
And naming Rome, ye land and sea *comprize*.
Spenser.

Necessity of shortness causeth men to cut off impertinent discourses, and to *comprise* much matter in few words. *Hooker.*

Do they not, under doctrine, comprehend the same that we intend by matters of faith? Do not they, under discipline, *comprise* the regimen of the church?
Id.

But with this sad news surprized,
Soon she let that niceness fall,
And would gladly yield to all
So it had his stay *comprized*. *Marell.*

The wretched have no country: that dear name
Comprizes home, kind kindred, fostering friends,
Protecting laws, all that binds man to man—
But none of these are mine;—I have no country.—
Maturin's Bertram.

COMPROBATION, *n. s.* Lat. *comprob*: Proof; attestation.

That is only esteemed a legal testimony, which receives *comprobation* from the mouths of at least two witnesses. *Browne.*

COMPROMISE, <i>n. s. & v. a.</i>	} Lat. <i>compro-</i> <i>missio</i> , <i>missum</i> . Compromise is a mutual promise of two or more parties at difference, to refer the ending of their controversies to the arbitrement or equity of one or more arbitrators. A compact or bargain, in which some concessions are made on each side. The verb signifies to compound; to adjust a compact by mutual concessions. Shakspeare uses it in the simple sense of to accord, and to agree.
COMPROMISSORIAL, <i>adj.</i>	

Wars have not wasted it, for warred he hath not,
Eut basely yielded, upon *compromise*,
That which his ancestors atchieved with blows.
Shakspeare. Richard II.

Laban and himself were *compromised*,
That all the yearlings, which were streaked and pied,
Should fall as Jacob's hire. *Id. Merchant of Venice.*

COMPROVINCIAL, *n. s.* From *con* and *provincial*. Belonging to the same province.

At the consecration of an archbishop, all his *comprovincials* ought to give their attendance.

Ayliffe's Parergon.

COMPT, <i>n. s. & v. a.</i>	} Lat. <i>computus</i> ; Fr. <i>compte</i> . Account; com- putation; reckoning. The verb is now spelt COUNT, which see The adjective is employed in the sense of accountants;
COMPTER, <i>n. s.</i>	
COMPTIBLE, <i>adj.</i>	

responsible; ready to give account; subject; submissive.

Good beauties, let me sustain my scorn; I am very *comptible* even to the least sinister usage. *Shakspeare.*

Your servants ever

Have theirs, themselves, and what is theirs, in *compt*. To make their audit at your highness' pleasure, Still to return your own. *Id. King John.*

Disdain not, Snow! my humble verse to hear,

Stick thy black pen awhile behind thy ear:

Whether thy *compter* shine with sums untold,

And thy wide-grasping hand grow black with gold.

Gay.

COMPTON (Henry), bishop of London, was the youngest son of Spencer earl of Northampton, and born in 1632. After the Restoration he became cornet of a regiment of horse; but soon after, quitting the army, was made bishop of Oxford in 1674; and in 1675 bishop of London. He was entrusted with the education of the two princesses Mary and Anne, whom he afterwards married to the princes of Orange and Denmark: and their firmness in the protestant religion was in a great measure owing to their tutor, to whom, when popery began to prevail at court, it was imputed as an unpardonable crime. He was suspended from his ecclesiastical functions by James II. but restored again on the prince of Orange's invasion. He performed the ceremony of the coronation of that prince; was appointed one of the commissioners for revising the liturgy; and labored with much zeal to reconcile dissenters to the church. His spirit of moderation made him unpopular with the clergy, and in all probability checked his further promotion. He died in 1713 having published a Treatise on the Communion; Seven Letters on Religious Subjects, and a Translation of the Jesuits' Intrigues.

COMPTONITE. A new mineral found in ejected masses on Mount Vesuvius. It occurs crystallised, in oblique four-sided prisms, truncated. The angles of the oblique prism are probably 90° 51' and 88° 9'. Transparent, or semi-transparent. Gelatinises with acids, and it is sometimes accompanied with acicular aragonite. It was first brought to this country by lord Compton, in 1818.

COMPTROLLER, *v. a.* } This word is writ-

COMPTROLLER, *n. s.* } ten by some authors,

COMPTROLLERSHIP, *n. s.* } who did not attend to the etymology, for control; and some of its derivatives are written in the same manner. To control; to over-rule; to oppose. The noun signifies director; supervisor; superior intendant; governor.

This night he makes a supper, and a great one, To many lords and ladies:

I was spoke to, with Sir Henry Guilford,

This night to be *comptrollers*. *Shakspeare. Henry VIII.*

The gayle for stannery-causes is annexed to the *comptroller*ship. *Carew's Survey of Cornwall.*

The *comptrollers* of vulgar opinions pretend to find out such a similitude in some kind of baboons.

Temple.

My fates permit me not from hence to fly;

Nor he, the great *comptroller* of the sky.

Dryden's Æneid.

COMPULSATORY, *adj.* } Lat. *compulsor*.

COMPULSATIVELY, *adv.* } Having the force of compelling; co-active; with force; by restraint.

Which is no other,

But to recover from us by strong hand.

And terms *compulsatory*, those foresaid lands

So by his father lost. *Shakspeare. Hamlet.*

COMPULSION, *n. s.* Lat. *compulsio*. The act of compelling to something. Force; violence of the agent; the state of being compelled; violence suffered.

Bound unto me; but not with such hard bands

Of strong *compulsion* and straight violence

As now in miserable state he stands;

But with sweet love and sure benevolence,

Voide of malicious mind or foul offence. *Spenser.*

Such sweet *compulsion* doth in musick lie,

To lull the daughters of necessity. *Milton.*

Compulsion thus transported! *Id. Paradise Lost.*

When the fierce foe hung on our broken rear,

With what *compulsion* and laborious flight

We sunk thus low. *Id.*

Compulsion is in an agent capable of volition, when the beginning or continuation of any action is contrary to the preference of his mind. *Locke.*

COMPULSIVE, *adj.* } Fr. *compulser*; Lat.

COMPULSIVELY, *adv.* } *compulsus*. Having the

COMPULSIVENESS, *n. s.* } power to compel; forcible.

The Danube, vast and deep,

Supreme of rivers! to the frightful brink,

Urged by *compulsive* arms, soon as they reached,

New terror chilled their veins. *Phillips.*

The clergy would be glad to recover their dues by

a more short and *compulsive* method. *Swift.*

COMPULSORY, *adj.* } Fr. *compulsoire*.

COMPULSORILY, *adv.* } Having the power of necessitating or compelling.

To say that the better deserver hath such right to govern, as he may *compulsorily* bring under the less worthy, is idle. *Bacon.*

He erreth in this, to think that actions, proceeding from fear, are properly *compulsory* actions; which, in truth, are not only voluntary, but free actions; neither compelled, nor so much as physically necessitated.

Bramhall against Hobbes.

Kindly it would be taken to comply with a patent, although not *compulsory*. *Swift.*

COMPUNCTION, *n. s.* } Fr. *compunction*,

COMPUNCTIONOUS, *adj.* } from Lat. *pungo*,

COMPUNCTIVE, *adj.* } *punctum*, to prick.

The power of pricking; stimulation; irritation. Applied to the mind, it signifies the throbbings of remorse.

Stop up the access and passage to remorse,

That no *compunctions* visitings of nature

Shake my fell purpose. *Shakspeare. Macbeth.*

This is that acid and piercing spirit, which, with such activity and *compunction*, invadeth the brains and nostrils of those that receive it.

Broene's Vulgar Errors.

He acknowledged his disloyalty to the king, with expressions of great *compunction*. *Clarendon.*

COMPURGATION, *n. s.* } Lat. *compur-*

COMPURGATOR, *n. s.* } *gatio*. The prac-

tice of justifying one man's veracity by the testimony of another. Compurgator is the agent who yields such testimony.

The next quarry, or chalk-pit, will give abundant attestation: these are so obvious, that I need not be far to seek for a *compurgator*.

Woodward's Natural History.

COMPUTE, *v. a. & n. s.* } Lat. *computo*. To
 COMPUTABLE, *adj.* } reckon; to calcu-
 COMPUTATION, *n. s.* } late; to number;
 COMPUTER, *n. s.* } to count. The deri-
 COMPUTIST. } vatives have this ex-
 clusive application.

My princely father
 Then, by just *computation* of the time,
 Found that the issue was not his.

Shakspeare. Richard III.

Though there were a fatality in this year, yet divers were out in their account, aberring several ways from the true and just *compute*; and calling that one year which perhaps might be another.

Broune's Vulgar Errors.

If, instead of twenty-four letters, there were twenty-four millions, as those twenty-four millions are a finite number, so would all combinations thereof be finite, though not easily *computable* by arithmetic.

Hale's Origin of Mankind.

And, as it works, the industrious bee
Computes its time as well as we. *Marvell.*

I have known some such ill *computors*, as to imagine the many millions in stocks so much real wealth.

Swift.

We pass for women of fifty: many additional years are thrown into female *computations* of this nature.

Addison's Guardian.

Alas! not dazzled with their noon-tide ray,
Compute the morn and evening to the day;
 The whole amount of that enormous fame,
 A tale that blends their glory with their shame. *Pope.*

The treasurer was a wise man, and a strict *computist*.

Wotton.

Did man *compute*

Existence by enjoyment, and count o'er
 Such hours 'gainst years of life,—say, would he name
 threescore. *Byron. Childs Harold.*

COMRADE, *n. s.* Fr. *camerade*, from *camera*, a chamber; one that lodges in the same chamber, *contubernio fruitur*. One who dwells in the same house or chamber. A companion; a partner in any labor or danger.

Rather I abjure all roofs, and chuse
 To be a *comrade* with the wolf and owl.

Shakspeare. King Lear.

He permitted them

To put out both thine eyes, and fettered send thee
 Into the common prison, there to grind
 Among the slaves and asses, thy *comrades*,
 As good for nothing else. *Milton's Agonistes.*

A footman, being newly married, desired his *comrade* to tell him freely what the town said of it. *Swift.*

His back was to the dashing spray—

Behind but close—his *comrades* lay.—

Byron. Bride of Abydos.

And then into a hoarser murmur grew,
 An ominous, and wild and desperate sound,
 And when his *comrades* thought each other knew,
 'Twas but his own, suppressed till now he found,
 And out they spake of lots of flesh and blood,
 And who should die to be his fellow's food.

Id. Don Juan.

CON. A Latin inseparable preposition, which, at the beginning of words, signifies union or association; as *concourse*, a running together; to *convene*, to come together. Some authors omit the final consonant, in various instances, as contemporary, instead of contemporary, but this practice is not to be recommended.

CON. A cant abbreviation of the Latin *contra*, against. Thus abridged it means the negative side of a question; and is always used in conjunction with the word *pro*.

Of many knotty points they spoke,
 And *pro* and *con* by turns they took. *Prior.*

CON, *v. a.* } Goth. *cunnan*; Swed. *kunna*;
 CO'NNER, *n.* } Ang.-Sax. *cennan*, *cunnan*. To
 CO'NNING, *n.* } have a knowledge of; to per-
 ceive; to study; to commit to memory; to learn;
 to look over. The first of the nouns is seldom, if
 ever used, but in the compound, an ale-conner.

Conning, which, as a noun, signifies knowledge, ability, is obsolete. Spenser says, 'Yet as I conne, my conning I will strain.' Shakspeare employs the phrase to con thanks, simply to express, to thank. 'I con him no thanks for't in the nature he delivers it.' It is thus exactly equivalent to the French phrase, *savoir gré*. See COND.

And saide, Sire Knight, here forth ne lith no way,
 Tell me what that ye seken by your fay,
 Peraventure it may the better be,
 These olde folk *con* mochel thing, quod she.

Chaucer. Cant. Tales.

Now certes I woldon my diligence
 To *conne* it all or Cristemasse he went. *Id.*

Ah! Cuddy, then quoth Colin, thou's a fon,
 That hast not seen least part of Nature's work:
 Much more there is unkend than thou dost kon.

Spenser. Colin Clout's come home again.

Each rowme she sought, but them all empty fond;
 That all were fled for feare, but whether nether kond.
Id. Faerie Queene.

Pretty answers! have you not been acquainted with goldsmiths wives, and *conned* them out of rings?

Shakspeare.

Our understanding cannot in this body arrive so clearly to the knowledge of God, and things invisible, as by orderly *conning* over the visible and inferior creatures.

Milton.

All this while John had *conned* over such a catalogue of hard words, as were enough to conjure up the devil.

Arbutnot.

My passions, when once lighted up, raged like so many devils, till they got vent in rhyme; and then the *conning* over my verses, like a spell, soothed all into quiet.

Burns.

CONARION, the pineal gland.

CONATUS, a term frequently used in philosophy and mathematics, defined by some to be a quantity of motion not capable of being expressed by any time or length; as the conatus *recedendi ab axemotus*, is the endeavour which a body, moved circularly, makes to recede, or fly off from the centre of its motions.

CONAWANGO, or CONWONGA, a river of the United States, which rises in New York, and runs into the Alleghany on the north side.

CONCA (Sir Sebastian), a celebrated historical and portrait painter, born at Gaeta in 1679. He was a disciple of the famous Francis Solimena; who employed him to sketch after his designs; and afterwards, by painting small portraits at a low price, he obtained a considerable fortune. By this means also he acquired great freedom of hand in pencilling and coloring. His great patron was cardinal Ottoboni, who introduced him to pope Clement XI., for whom he

executed the picture of Jeremiah, in the church of St. John de Lateran, with universal applause. This pope, in a general assembly of the academicians of St. Luke, conferred on him the order of knighthood. Almost all the churches and chapels of Italy are enriched with his compositions. He was earnestly invited by Philip V. of Spain to visit his court, but could not be prevailed on to leave Rome. He painted two admirable pictures for the king of Poland, with figures as large as life; the one representing Alexander presenting Bucephalus to Philip, the other Alexander's marriage with Roxana. In 1757 Philip V. of Spain ennobled him. He was then seventy-eight, and died in 1761, aged eighty-two.

CONCAMERATE, *v. a.* } Lat. *concamero* ;
CONCAMERATION, *n. s.* } Gr. *καμαρα*. To arch or vault over; to bend over in a concave form. The noun signifies an arch; a vault.

Of the upper beak, an inch and a half consisteth of one *concamerated* bone, bended downwards, and toothed as the other. *Gray's Museum.*

What a romance is the story of those impossible *concamerations*, and feigned rotations of solid orbs!

Glawville's Sceptis.

CONCAN, a district of southern India, on the west coast of Hindostan, in the province of Bejapore. It is separated from the rest of the continent by the western Ghauts. The country declines gradually from the mountains towards the sea, and is intersected by a number of small streams. The coast is broken into a number of small bays and harbours; and, as the land and sea breezes blow alternately on and from the coast, vessels steering along it are obliged to keep within sight of land. When the Moguls seized Hindostan they found this coast infested with pirates, and fitted out a fleet to protect their vessels. The Mahrattas armed against the Moguls, ravaged their possessions, and fitted out a fleet to protect the pirates. On this Conjee Angria, governor of Severndroog, one of the best fortresses on the coast, formed an independent state, and in a short time extended his dominions forty leagues along the coast, and six towards the mountains. His successors took the name of Angria, and made peace with the Mahrattas, on paying an annual tribute. They continued to make depredations on the coast, and to seize all vessels that passed that way, till 1756, when their fleet was destroyed, and the strong fort of Gheria, where the chief resided, was taken by admiral Watson and colonel Clive. The whole country, with the exception of Bancote, was now restored to the Mahrattas. The principal towns are Choul, Bancote or Fort Victoria, Dabal or Severndroog, Gheria, Tamana, and Rajpore. Concan lies between 16° and 19° N. lat.

CONCARNEAU, a sea-port town of France, in the department of Finisterre. It is ten miles S. S. E. of Quimper, and has a castle. Inhabitants, who live by the pilchard fishery, about 2000.

CONCATENATE, *v. a.* } Old Fr. *concathe-*
CONCATENATION, *n. s.* } *nation*; from Lat. *catena*, a chain. The old English spelling was

identical with the French. To link together; to connect in a successive order. The noun signifies a series of links; an unbroken succession.

If Chapman affected the reputation of rendering line for line, the specious expedient of chusing a protracted measure, which *concatenated* two lines together, undoubtedly favoured his usual propensity to periphrasis. *Warton. Hist. Eng. Poetry.*

The stoicks affirmed a fatal unchangeable *concatenation* of causes reaching even to the elicit acts of man's will. *South.*

CONCAVE, *v., n. s. & adj.* } Fr. *concave* ;
CONCAVATION, *n. s.* } Sp. and Ital.
CONCAVENESS, *n. s.* } *concavo* ; Lat.
CONCAVITY, *n. s.* } *concavus*. The
CONCAVOUS, *adj.* } interior; the hol-
CONCAVOUSLY, *adv.* } low of any spheri-

cal, spheroidal, or elliptical body, as of a bowl, an arch, or an egg-shell, is *concave*: the word is opposed to *convex*, which denotes the exterior of such a body. The derivative words, of course, follow the meaning of the primary. We use the word *hollow* as synonymous with *deceitful*; and Shakspeare uses the word *concave* in the same sense.

Have you not made an universal shout,
 That Tyber trembled underneath his banks,
 To hear the replication of your sounds
 Made in his *concave* shores?

Shakspeare. Julius Cæsar.

For his vority in love, I do think him as *concave* as a covered goblet, or a worm-eaten nut.

Id. As You Like It.

The dolphin that carrieth Arion is *concavously* inverted, and hath its spine depressed.

Brown's Vulgar Errors.

At which the universal host sent up
 A shout that tore hell's *concave*.

Milton's Paradise Lost.

Niches that contain figures of white marble should not be coloured in their *concavity* too black. *Wotton.*

These great fragments falling hollow, inclosed under their *concave* surface a great deal of air.

Burnet's Theory.

Serene, though awful, on her brow the light
 Of heavenly wisdom shone: nor roved her eyes,
 Save to the shadowy cliff's majestic height,
 Or the blue *concave* of the' involving skies. *Beattie.*

Into the western bay, *concealed* by vast mountains,
 western winds only can blow. *Anne Seward.*

So on the shoreless air the intrepid Gaul
 Launched the vast *concave* of his buoyant ball.

Darwin.

Where lighter gases, circumsufed on high,
 Form the vast *concave* of exterior sky. *Id.*

CONCAVO-CONCAVE, *adj.* Concave or hollow on both sides.

CONCAVO-CONVEX, *adj.* From *concave* and *convex*. Concave one way and convex the other.

I procured another *concavo-convex* plate of glass, ground on both sides to the same sphere with the former plate. *Newton.*

A *concavo-convex* pentangular plate, part of a shell that belongs to the entrochus. *Woodward on Fossils.*

CONCAUSE. From *con* and *cause*. A cause which co-operates with another.

A *concause* or instrument.

Cudworth.

CONCEAL, *v. a.* } Fr. *celer*; Lat. *concolo*. To keep
CONCEALABLE, *adj.* } hidden, secret, undi-
CONCEALEDLY, *adv.* } vulged; to secrete
CONCEALEDNESS, *n. s.* } from search; to dis-
CONCEALER, *n. s.* } semble. Conceal-
CONCEALING, *n. s.* } ment is the act of
CONCEALMENT, *n. s.* } hiding, of keeping secret; the state of being
 hidden; the place wherein a person or thing is
 concealed; a place of retirement or shelter.

I thither went, where I did long conceal
 Myself, till that the dwarf did me reveal.

Spenser's Faerie Queene.

Thus merely with the garment of a grace
 The naked and concealed fiend he covered,
 That the unexperienced gave the tempter place,
 Which like a cherubim above them hovered.

Shakspeare. A Lover's Complaint.

Come, Catesby, thou art sworn
 As deeply to effect what we intend,
 As closely to conceal what we impart.

Id. Richard III

She never told her love ;

But let concealment, like a worm i' th' bud,
 Feed on her damask cheek.

Id. Twelfth Night.

He is a worthy gentleman,
 Exceedingly well read, and profited
 In strange concealments.

Id. Henry IV.

Returning a lye unto his Maker, and presuming to
 put off the Searcher of Hearts, he denied the omnisci-
 ency of God, whereunto there is nothing concealable.

Browne's Vulgar Errors.

They were to undergo the penalty of forgery, and
 the concealer of the crime was equally guilty.

Clarendon.

There is but one way I know of conversing safely
 with all men, that is, not by concealing what we say
 or do, but by saying or doing nothing that deserves to
 be concealed.

Popc.

A person of great abilities is zealous for the good
 of mankind, and as solicitous for the concealment
 as the performance of illustrious actions.

Addison's Frecholder.

The cleft tree

Offers its kind concealment to a few.

Their food its insects, and its moss their nests.

Thomson.

Quick, blushing as abashed, she half withdrew ;

One hand a bough of flowering myrtle waved,

One graceful spread, where, scarce concealed from
 view,

Soft through the parting robe her bosom heaved.

Beattie.

That hour arrived, his work begins ;

He spins and weaves, and weaves and spins ;

Till circle upon circle wound

Careless around him and around,

Conceals him with a veil, though slight,

Impervious to the keenest sight.

Courper.

But now beneath this walnut shade,

He finds his long last home,

And waits, in snug concealment laid,

Till gentler Puss shall come.

Id.

The London ladies were always too handsome for
 me ; then they are so defaced ; such a circumvallation
 of hoop, with a breast-work of whalebone, that
 would turn a pistol-bullet, much less Cupid's arrows,
 then turret on turret on top, with a store of concealed
 weapons, under pretence of black pins,—and above
 all, a standard of feathers that would do honour to a
 knight of the bath. Upon my conscience, I could as
 soon embrace an Amazon, armed at all points.

Sheridan.

Her head hung down, and her long hair, in stoop-
 ing,

Concealed her features better than a veil :

And one hand o'er the ottoman lay drooping,

White, waxen, and as alabaster pale.

Byron's Don Juan.

CONCEDE, *v. a.*

CONCESSION, *n. s.*

CONCESSIONARY, *adj.*

CONCESSIVE, *adj.*

CONCESSIVELY, *adv.*

Fr. and Span. *conceder*; Ital. and Lat. *concedere*, from Lat. *con* and *cedere*. To concede is to give up; to admit; to allow without dispute; to relinquish; to resign. Concession is the act of giving up; the thing so given up. Concessionary signifies that which is granted not as a right, but as an indulgence. Concessive, that which implies concession; concessively, by way of concession, granting the premises.

By expurgatory animadversions we might strike out great numbers of hidden qualities; and, having once a conceded list, we might with more safety attempt their reasons.

Browne.

Some have written rhetorically and concessively; not controverting, but assuming the question, which, taken as granted, advantaged the illation.

Id.

I still counted myself undiminished by my largest concessions, if by them I might gain the love of my people.

King Charles.

The concession of these characters was in a parliamentary way.

Hale's Common Law of England.

When a lover becomes satisfied by small compliances, without further pursuits, then expect to find popular assemblies content with small concessions.

Swift.

The atheist, if you concede to him that fortune may be an agent, doth presume himself safe and invulnerable.

Bentley.

Hypothetical, conditional, concessive, and exceptive conjunctions, seem in general to require a subjunctive mood after them.

Lowth's Grammar.

I wished you to concede to America, at a time when she prayed concession at our feet. Just as much was I an American when I wished parliament to offer terms in victory, and not to wait the well chosen hour of defeat, for making good by weakness, and by supplication, a claim of prerogative, preeminence, and authority.

Burke.

CONCEIT, *v. n. & n. s.*

CONCEITED, *adj.*

CONCEITEDLY, *adv.*

CONCEITEDNESS, *n. s.*

CONCEITIVE, *adj.*

CONCEITLESS, *adj.*

Fr. *conceit*; Sp. *concepto*; Ital. *concepto*; Lat. *conceptus*. Both the verb and the noun have various shades of meaning, some of which are become obsolete. They are disused in a good sense, and are now employed only as expressive of more or less of censure. The noun formerly signified a conception; an idea; an image formed by the mind; understanding; quickness of apprehension; a pleasant fancy; gaiety of imagination; acuteness: it now generally means a fantastical notion; a thought more brilliant than correct; opinionative pride; self-sufficiency. The verb and the participial adjective have shared the same fate. To be conceited once denoted, to be endowed with fancy; it is now applied to vain persons, to men who, without any good grounds, have lofty ideas of their own merit. This word is used with of before the object of conceit. Conceitedly, is fantastically; whimsically. Conceitless, is stupid

devoid of thought. The phrase, out of conceit with, means to have ceased to have a liking for the thing spoken of; it implies previous regard changed into an opposite feeling.

I shall be found of a quick conceit in judgment, and shall be admired. *Wisdom*, viii. 11.

Seest thou a man wise in his own conceit? There is more hope of a fool than of him.

Proverbs, xxv. 12.

A foolish faune indeed,

That couldst not hold thyself so hidden blest,
But wouldest needs thine own conceit aread.

Spenser's Faerie Queene.

How often, alas! did her eyes say unto me, that they loved! and yet I, not looking for such a matter, had not my conceit open to understand them. *Sidney*.

The first kind of things appointed by laws humane, containeth whatsoever is good or evil, is notwithstanding more secret than that it can be discerned by every man's present conceit, without some deeper discourse and judgment. *Hooker*.

One of two bad ways you must conceit me,
Either a coward, or a flatterer.

Shakespeare. Julius Caesar.

I shall not fail to approve the fair conceit

The king hath of you. *Id. Henry VIII.*

I know not how conceit may rob

The treasury of life, when life itself

Yields to the theft. *Id. King Lear*.

His wit is as thick as Tewksbury mustard: there is no more conceit in him than is in a mallet.

Id. Henry IV.

Thinkst thou I am so shallow, so conceitless,

To be seduced by thy flattery.

Id. Two Gentlemen of Verona.

They looked for great matters at their hands, in a cause which they conceited to be for the liberty of the subject. *Bacon*.

He was of countenance amiable, of feature comely, active of body, pleasantly conceited, and sharp of wit.

Knolles.

Conceitedly dress her, and be assigned

By you fit place for every flower and jewel:

Make her for love fit fuel. *Donne*.

The strong, by conceiting themselves weak, are thereby rendered as unactive, and consequently as useless, as if they really were so. *South's Sermons*.

Every man is building a several way, impotently conceited of his own model and his own materials.

Dryden.

Strong conceit, like a new principle, carries all easily with it, when yet above common sense. *Locke*.

Not that I dare assume to myself to have put him out of conceit with it, by having convinced him of the fantasticalness of it. *Tillotson, Preface*.

When men think none worthy esteem, but such as claim under their own pretences, partiality and conceitedness make them give the pre-eminence.

Collier on Pride.

What you write of me, would make me more conceited than what I scribble myself. *Pope*.

Some to conceit alone their works confine,

And glittering thoughts struck out at every line. *Id.*

Malbranche has an odd conceit,

As ever entered Frenchman's pate. *Prior*.

Since by a little studying in learning, and great conceit of himself, he has lost his religion; may he find it again by harder study, under humbler truth.

Bentley.

The conceit of Mr. Hobbes, that in the nature of things there is no distinction between just and unjust, right and wrong; and that in civil society the will of human governors is the sole standard of duty, and

consequently of the law of nature; this conceit, I say, we need not stop to examine. *Beattie*.

Philosophy, without his heavenly guide,

May blow up self conceit, and nourish pride,

But, while his province is the reasoning part,

It has still a veil of midnight on his heart. *Cowper*.

Our baritone I almost had forgot,

A pretty lad, but bursting with conceit—

With graceful action, science not a jot,

A voice of no great compass, and not sweet.

Byron's Don Juan.

CONCEIVE, *v. a. & n.*

CONCEIVER, *n.*

CONCEIVING, *n. s.*

CONCEIVABLE, *adj.*

CONCEIVABLENESS, *n.*

CONCEIVABLY, *adv.*

Fr. *concevoir*; Ital.

concepere; Sp. *con-*

cepere; Lat. *conci-*

perere. To receive

into, or form in, the

uterus; to form in

the mind; to comprehend; to think; to be of opinion that; to have an idea of; to become pregnant. Conceiving is apprehension; understanding. The derivatives do not stand in need of being defined.

I was shapen in iniquity, and in sin did my mother conceive me. *Psaln li. 5.*

Nebuchadnezzar hath conceived a purpose against you. *Jeremiah*.

There is a maner tree, as saith Saint Isidore, that whan men make a fire of the saide tree, and cover the coles of it with ashen, sothly the fire thereof wol last all a yere or more: and right so farth it of rancour when it is ones conceived in the herte of som men.

Chaucer's Canterbury Tales.

Sorowes many hath she suffrid trewly

Sith that she first conceived him and bare. *Id.*

What comfort can I wofull wretch conceive!

Or why should ever I henceforth desyre

To see faire heaven's face, and life not leave,

Sith that false traytour did my honour reeve?

Spenser's Faerie Queene.

It were a goodly storie to declare

By what strange accident faire Chrysgone

Conceived these infants. *Id.*

Her fickle hart conceived hasty fyre,

Like sparkes of fire that fall in slender flex. *Id.*

From her fayre eyes he took commandment,

And ever by her lookes conceived her intent. *Id.*

The grieved commons

Hardly conceive of me: let it be noised,

That, through our intercession, this revokement

And pardon comes. *Shakespeare. Henry VIII.*

This kiss, if it durst speak,

Would stretch thy spirits up into the air:

Conceive, and fare thee well. *Id. King Lear*.

Cadwal

Strikes life into my speech, and shows much more

His own conceiving. *Id. Cymbeline*.

O what avails me now that honour high,

To have conceived of God! or that salute,

Itail, highly favoured, among women blest!

Milton.

Though hereof prudent symbols and pious allegories be made by visor conceivers, yet common heads will fly unto superstitious applications.

Broune's Vulgar Errors.

This man conceived the duke's death; but what was the motive of that felonious conception, is in the clouds. *Wotton*.

If it were possible to contrive an invention, whereby any conceivable weight may be moved by any conceivable power, with the same quickness, without other instrument, the works of nature would be too much subject to art.

Wilkins.

The freezing of the words in the air, in the northern climes, is as *conceivable* as this strange union.

Glawille's Scepis.

The beauteous maid, whom he beheld, possessed;
Conceiving as she slept, her fruitful womb
Swelled with the founder of immortal Rome.

Addison.

Conceive of things clearly and distinctly in their own natures; *conceive* of things completely in all their parts; *conceive* of things comprehensively in all their properties and relations; *conceive* of things extensively in all their kinds; *conceive* of things orderly, or in a proper method.

Watts's Logick.

Faults in the life breed errors in the brain:

And these reciprocally those again.

The mind and conduct mutually imprint

And stamp their image in each other's mint:

Each, sire and dam, of an infernal race,

Begetting and *conceiving* all that's base. *Cowper.*

Nothing can be *conceived* more hard than the heart of a thorough-bred metaphysician. It comes nearer to the cold malignity of a wicked spirit than to the frailty and passion of a man. *Burke.*

Although no man can command his conviction, I have ever considered a deliberate disposition to make proselytes in infidelity as an unaccountable depravity. Whoever attempts to pluck the belief or the prejudice on this subject, style it which he will, from the bosom of one man, woman, or child, commits a brutal outrage, the motive for which I have never been able to trace or *conceive*. *Sheridan.*

CONCELEBRATE. Old Fr. *concelebrer*;
Lat. *concelebro*. To praise; to celebrate together.

CONCENT, v. & a.

CONCENTFUL, adj.

CONCENTED, part. adj.

CONCENTUAL, adj.

concento, Lat. *concentus*. The verb signifies singing together; the noun, a concert of voices; harmony; concord of sounds; and thence, figuratively, being consistent with; being in unison with. *Concentual* denotes harmonious.

All which together song full cherfully

A lay of love's delight with sweet *concent*.

Spenser's Faerie Queene.

Such musicke is wise words with time *concented*.

Id.

It is to be considered, that whatsoever virtue is in numbers, for conducting to *concent* of notes, is rather to be ascribed to the ante-number than to the entire number. *Bacon.*

Reasons borrowed from nature and the school-men, as subservient mediums, carry a musicke and *concent* to that which God hath said in his word. *Dr. Maine.*

'Tis in *concent* to his own principles, which allow no merit, no intrinsic worth, to accompany one state more than another. *Atterbury.*

Milton, full of these platonick ideas, has here a reference to this consummate or *concentual* song of the ninth sphere. *Warton. Notes on Milton.*

CONCENTRATE, v. a.

CONCENTRATION, n. s. } Fr. *concentrer*;
} Lat. *con* and *centrum*; κεντρον. To compress into a small compass; to impel from all points towards the centre; the opposite of expanding or dilating. The act of so compressing or impelling.

Spirit of vinegar, *concentrated* and reduced to its greatest strength, will coagulate the serum.

Arbuthnot on Aliments.

All circular bodies that receive a *concentration* of the light, must be shadowed in a circular manner.

Peacham, on Drawing.

The phenomena of chemical explosions cannot be accounted for without the supposition, that some of the bodies employed contain *concentrated* or solid heat combined with them, to which the French chemists have given the name of *ealorique*. *Darwin.*

Not that he was not sometimes rash, or so,
But never in his real and serious mood;
Then calm, *concentrated*, and still, and slow,
He lay coiled, like the boa in the wood;

Byron. Don Juan.

A kiss of youth and love,
And beauty, all *concentrating* like rays
Into one focus, kindled from above. *Id.*

CONCENTRE, v. a. & n. } Fr. *concentrer*;
CONCENTRICAL, adj. } Lat. *con* and *centrum*.
CONCENTRICK, adj. } The verb
CONCENTRICALLY, adv. } in its active
CONCENTRICKLY, adv. } meaning, is syn-
onymous with *concentrate*; in its neuter sense it signifies, to tend to a common centre; to have a centre in common with something else. Ben Jonson uses the word *concentric* as a noun, 'we are all *concentricks*.'

If, as in water stirred, more circles be
Produced by one, love such additions take;
Those, like so many spheres, but one heaven make;
For they are all *concentrick* unto thee. *Danne.*

In the *concentring* all their precious beams
Of sacred influence! *Milton.*

The bricks having first been formed in a circular mould, and then cut, before their burning, into four quarters or more, the sides afterwards join so closely, and the points *concentre* so exactly, that the pillars appear one intire piece. *Wotton.*

The having a part less to animate, will serve to *concentre* the spirits, and make them more active in the rest. *Decay of Piety.*

If a stone be thrown into stagnating water, the waves excited thereby continue some time to arise in the place where the stone fell into the water, and are propagated from thence into *concentrick* circles upon the surface of the water to great distances. *Newton's Opticks.*

Whatever turns the soul inward on itself, tends to *concentre* its forces, and to fit it for greater and stronger flights of science. By looking into physical causes, our minds are opened and enlarged; and in this pursuit, whether we take or whether we lose our game, the chase is certainly of service. *Burke.*

Whence in bright floods the vital air expands,
And with *concentric* spheres involves the lands. *Darwin.*

Turn to the Virtues—how different the decree!
Formed to connect, to blend, to associate, and to cooperate; bearing the same course, with kindred energies and harmonious sympathy, each perfect in its own lovely sphere, each moving in its wider or more contracted orbit, with different, but *concentring* powers, guided by the same influence of reason, and endeavouring at the same blessed end—the happiness of the individual, the harmony of the species, and the glory of the Creator. *Sheridan.*

All heaven and earth are still: from the high host
Of stars, to the lulled lake and mountain-coast,
All is *concentered* in a life intense,
Where not a beam, nor air, nor leaf is lost,
But hath a part of being, and a sense
Of that which is of all Creator and defence.
Byron's Child Harold.

CONCEPTACLE, *n. s.* Old Fr. *conceptacle*; Lat. *conceptaculum*. That in which any thing is contained; a vessel.

There is at this day resident, in that huge *conceptacle*, water enough to effect such a deluge.

Woodward's Natural History, Preface.

CONCEPTION, *n. s.* Fr. *conception*; Ital. **CONCEPTIBILE**, *adj.* } *conceptimento*; Span. **CONCEPTIOS**, *adj.* } *concepcion*; Lat. **CONCEPTIVE**, *adj.* } *ceptio*. Being received or held within, is the primary idea of the noun. With reference to the body, it means the act of becoming pregnant. As relating to the intellect, it signifies an idea; notion; purpose; the power of apprehending; the state of being conceived. Dryden uses it in the sense of a conceit, a pointed thought; but this meaning, even if it were ever given to the word by any one else, which is doubtful, is become obsolete. *Conceptible* denotes intelligible, fit to be conceived or understood; *conception*, that which is fertile, ready to conceive; and *conceptive*, that which has the capability of conceiving.

I will greatly multiply thy sorrow by thy *conception*; in sorrow thou shalt bring forth children.

Genesis, iii. 16.

Her berth was of the wombe of morning dew,
And her *conception* of the ioyous prime.

Spenser's Faerie Queene.

Joy had the like *conception* in our eyes,
And, at that instant, like a babe sprung up.

Shakspeare.

Please your highness, note
His dangerous *conception* in this point:
Not friended by his wish to your high person,
His will is most malignant, and it stretches
Beyond you to your friends. *Id. Henry VIII.*

Common mother,

Ensear thy fertile and *conception*s womb;
Let it no more bring out to ingrateful man.

Id. Timon.

And as if beasts conceived what reason were,
And that *conception* should distinctly show
They should the name of reasonable bear;
For, without reason, none could reason know. *Davies.*

In hot climates, and where the uterine parts exceed in heat, by the coldness of this simple they may be reduced into a *conceptive* constitution.

Broune's Vulgar Errors.

Some of his attributes, and the manifestations thereof, are not only highly delectable to the intellectual faculty, but are more suitable and easily *conceptive* by us, because apparent in his works.

Hale's Origin of Mankind.

As *conceptions* are the images or resemblances of things to the mind within itself, in the like manner are words or names the marks, tokens, or resemblances of those *conceptions* to the minds of them whom we converse with. *South's Sermons.*

Our own productions flatter us: it is impossible not to be fond of them at the moment of their *conception*.

Dryden's Dufresnoy.

He is too flatulent sometimes, and sometimes too dry; many times unequal, and almost always forced; and, besides, is full of *conceptions*, points of epigram, and witticisms; all which are not only below the dignity of heroic verse, but contrary to its nature.

Dryden's Juvenal, Dedication.

Whether they will call those immediate objects of their mind in thinking ideas or no, is perfectly in their own choice. If they dislike that name, they may call

them notions or *conceptions*, or how they please; it matters not, if they use them so as to avoid obscurity and confusion. *Locke.*

I have always thought that truth and knowledge, by the ill and over eager management of controversies, lose a great deal of the advantages they might receive from the variety of *conceptions* there is in men's understandings. *Id.*

The petty interests of such gentlemen, their low *conceptions* of things, their fears arising from the danger to which the very arduous and critical situation of public affairs may expose their places; their apprehensions from the hazards to which the discounts of a few popular men at elections may expose their seats in parliament; all these causes trouble and confuse the representations which they make to ministers of the real temper of the nation. *Burke.*

But in his delicate form—a dream of love,
Shaped by some solitary nymph, whose breast
Longed for a deathless lover from above,
And maddened in that vision—are exprest
All that ideal beauty ever blest
The mind within its most unearthly mood,
When each *conception* was a heavenly guest.

Byron's Child of Harold.

CONCEPTION, in physiology, the first formation: of the embryo, or fœtus, in the womb. See ANATOMY, *par.* 19—30.

CONCEPTION, in logic, the simple apprehension or perception which we have of anything, without proceeding to affirm or deny anything about it. Lord Kames justly distinguishes between *conception* and *perception*; making the latter to denote the consciousness of an object when present, or to include the reality of its object; whereas *conception* expresses the forming an idea of an object whether present or absent, or without any conviction of its reality.

CONCEPTION, a city of South America, called also Penco, is the second city of Chili in rank, and stands on the north side of the Biobio a league from the sea. It was originally built three leagues to the north of its present position, and has been twice destroyed by earthquakes. Talcahuano, the port of the present city, is six miles distant, on the south-west side, of the bay of Conception. This is one of the largest and safest bays on the coast of the Pacific. It is ten miles long from north to south, and nine from east to west. The mouth opens towards the north, and is divided by the island of Quiriquina into two channels: the eastern and safest is two miles broad, and the western about a mile and a half. Both have sufficient depths of water for the largest vessels. There is good anchorage under the south side of the island of Quiriquina, but the best is at the south-west extremity of the bay, opposite the town of Talcahuano. The new city, built in 1763, is said to have once contained 20,000 inhabitants; but the events of the late revolution have desolated it; and Mr. Miers did not consider it to contain above a fourth of that population at the period of his late travels in Chili. Extreme poverty, he says, was the universal appearance of the place: its cathedral, palace, and public buildings, being destroyed, and its trade annihilated.

By this name, as well as that of Penco, the entire province of Puchacal is sometimes called: an extremely fertile district, extending from that

of Rere on the east to the Pacific Ocean, and from the province of Itata south to the Indian territory of Arauco, from which it is separated by the Biobio. 'The bay of Conception, with its secure ports,' says the above writer, 'its vicinity to the city of Conception, formerly the capital of Chili, the convenience of river navigation in the interior, the greater productiveness of soil in the adjacent territory, its climate more congenial to activity and industry, present much greater advantages for commercial traffic than Valparaiso, or any other port or harbour in Chili; and will, no doubt, in time become of the greatest importance.'

CONCEPTION, a town of North America, in New Spain, and in the audience of Guatimala. It is seated near the sea coast, 100 miles west of Porto Bello. Long. 81° 45' W., lat. 10° 0' N.

CONCEPTION, a town of the province and government of Paraguay, situate about ninety miles north of Assumption. Long. 57° 16' W., lat. 23° 23' S.—Also a small place in the island of Itamarca, on the coast of Brasil—a settlement of South America, in New Grenada, in the province of San Juan de los Llanos, on the river Meta—and the name of a number of other minor settlements scattered throughout South America.

CONCEPTION, a bay in the gulf of California, North America.—Also a bay of Chili.

CONCEPTION BAY, a large bay on the east coast of Newfoundland, between Cape St. Francis on the south and Flamborough-head north. It has numerous small harbours on the west side, where are the two settlements Carboniere and Havre de Grace.

CONCEPTION DEL PAO, a town of the province and government of Caraccas, situated near the plains of the Orinoco. It contains a population of about 2300 inhabitants, who are generally in good circumstances. There is good water near the place; but the heat is excessive, and the inundations, occasionally; terrible. Cattle are exported in large numbers by the Guarapiche, or by the Orinoco. It is 125 mile S. S. W. of Barcelona, 165 south-west of Cumana, and eighty-four south-east of Caraccas.

CONCEPTION, IMMACULATE, OF THE HOLY VIRGIN, is a popish festival, held on the 8th of December, and established in honor of the virgin Mary, on the supposition of her having been conceived and born immaculate, i. e. without original sin. The immaculate conception is the great point of controversy between the Scotists and Thomists; the former maintaining, and the latter impugning it. In the three Spanish military orders, of St. James of the sword, Calatrava, and Alacantara, the knights take a vow at their admission, to defend the immaculate conception. This resolution was first taken in 1052. Peter d'Alva has published forty-eight huge volumes in folio on the Mysteries of the Conception.

CONCERN, *v. & n.* } Fr. *concerner* ;
 CONCERNANCE, *n.* } Ital. *concernere* ;
 CONCERNEDLY, *adv.* } Span. *concernir* ;
 CONCERNEDNESS, *n.* } low Lat. *concerno*.
 CONCERNING, *n. & prep.* } The primary word,
 CONCERNMENT, *n.* } and all its deriva-
 tives, imply something which excites considerable interest; something which is important in a worldly or moral point of view, whether with

relation to ourselves or to those who are dear to us. To be concerned, is to be anxious; to be much affected; to be sorry for; to participate in. To concern himself, has a condemnatory meaning; it indicates that the person spoken of meddles with that which does not concern him; that he acts intrusively. Concerning, as a preposition, has the meaning of relating to; as a noun, used by Shakspeare and others, it stands for business, affairs of moment. In familiar parlance, an extensive trade or business is called a large concern.

Vouchsafe ye then, whom only it concerns,
 To me those secret causes to display,
 For none but you, or who of you it learns,
 Can rightfully aread so doleful day.

Spenser. The Tears of the Muses.

A poet thrastest into the midst, even where it most concerneth him, and there recouring to the things forepaste, and divining of things to come, maketh a pleasing analysis of all.

Id. to Sir W. Raleigh.

Exclude the use of natural reasoning about the sense of Holy Scripture, concerning the articles of our faith; and then, that the Scripture doth concern the articles of our faith, who can assure us? *Hooker.*

Count Claudio may hear; for what I would speak of concerns him. *Shakspeare.*

I would not

The cause were known to them it most concerns. *Id.*

We shall write to you,

As time and our concernings shall importune. *Id.*

There is not any thing more subject to error, than the true judgment concerning the power and forces of an estate. *Bacon.*

Gracious things

Thou hast revealed; those chiefly which concern

Just Abraham, and his seed.

Milton's Paradise Lost.

To mix with thy concernments I desist

Henceforth, nor too much disapprove my own.

Id. Agonistes.

Sir, 'tis of near concernment, and imports

No less than the king's life and honour.

Denham's Sophy.

He married a daughter to the earl, without any other approbation of her father, or concernment in it, than suffering him and her to come into his presence.

Clarendon.

They had more positively and concernedly wedded his cause, than they were before understood to have done. *Id.*

Providence, where it loves a nation, concerns itself to own and assert the interest of religion, by blasting the spoilers of religious persons and places.

South's Sermons.

When my concernment takes up no more room or compass than myself, then, so long as I know where to breathe and to exist, I know also where to be happy. *Id.*

Ah, what concerns did both your souls divide!

Your honour gave us what your love denied.

Dryden.

While they are so eager to destroy the fame of others, their ambition is manifest in their concernments. *Id.*

Being a layman, I ought not to have concerned myself with speculations which belong to the profession. *Id.*

Mysterious secrets of a high concern,
 And weighty truths, solid convincing sense,

Explained by unaffected eloquence.

Roscommon.

The well educating of their children is so much the duty and the *concern* of parents, and the welfare and prosperity of the nation so much depends on it, that I would have every one lay it seriously to heart.

Locke.

No doubt Ulysses, who was a prudent man, preached up passive obedience, and exhorted them to a quiet submission, by representing to them of what *concernment* peace was to mankind.

Id.

This manner of exposing the private *concerns* of families, and sacrificing the secrets of the dead to the curiosity of the living, is one of those licentious practices, which might well deserve the animadversion of our government.

Addison's Frecholder.

Why all this *concern* for the poor? We want them not, as the country is now managed: where the plough has no work, one family can do the business of fifty.

Swift.

Propositions which extend only to the present life, are small, compared with those that have influence upon our everlasting *concernments*.

Watts on the Mind.

Ah, what have I to do with conquering kings,
Hands drenched in blood, and breast begirt with steel!

To those whom Nature taught to think and feel,
Heroes, alas! are things of small *concern*.

Beattie.

He sees that this great roundabout,
The world, with all its motley rout,
Church, army, physic, law,
Its customs, and its businesses,
Is no *concern* at all of his,
And says—what says he?—Caw.

Cooper.

There's no more to be said of Trafalgar,
'Tis with our hero quietly inar'd;
Because the army's grown more popular,
At which the naval people are *concern'd*.

Byron's Don Juan.

CONCERT, *v. a., v. n. & n. s.* Fr. *concerter*; Ital. *concertare*; Span. *concertar*; Lat. *concertare*. To form a plan together; to make preparation together for something that is to be done. The noun, as referring to the verb, signifies the act of communicating a design; the conjoint taking of proper measures to accomplish some purpose. In its second sense, the connexion of which with the first is obvious, it means many persons or instruments combined in one performance. See CONSORT.

Mark how, already, in his working brain
He forms the wail *concerted* scheme of mischief.

Rowe.

All these discontents, how ruinous soever, have arisen from the want of a due communication and *concert*.

Swift.

Will any man persuade me that this was not, from the beginning to the end, a *concerted* affair?

Tatler.

When a number of persons, not acting in *concert*, having no interest to disguise what is true, or to affirm what is false, and competent judges of what they testify, concur in making the same report, it would be accounted folly to disbelieve them, especially if what they testified were credible in itself.

Beattie.

Whilst men are linked together, they easily and speedily communicate the alarm of any evil design. They are enabled to fathom it with common counsel, and to oppose it with united strength. Whereas, when they lie dispersed, without *concert*, or order, or discipline, communication is uncertain, counsel difficult, and resistance impracticable.

Burke.

Nature, exerting an unwearied power,
Forms, opens, and gives scent to every flower;
Spreads the fresh verdure of the fields, and leads
The dancing Naiads through the dewy meads:

She fills profuse ten thousand little throats
With music, modulating all their notes;
And charms the woodland scenes and wilds unknown
With artless airs and *concerts* of her own.

Cooper.

CONCERTATION, *n. s.* } Lat. *concertatio*.
CONCE'RTATIVE, *adj.* } Strife; struggling
with; contention; contentious; prone to quarrel.

I wish to him whatever good himself desires to himself; these *concertations* between us notwithstanding.

Life of Firmin.

CONCERTO, Ital. *concerto*. A piece of music.

If that be the fashion I never will give
Any grand entertainment as long as I live;
For I'm of opinion, 'tis proper to cheer
The stomach and bowels, as well as the ear.
Nor me did the charming *concerto* of Abel,
Regale like the muffins I saw on the table.

Astley.

With wire and catgut he concludes the day,
Quavering and semiquavering care away.
The full *concerto* swells upon your ear;
All elbows shake. Look in, and you would swear
The Babylonian tyrant with a nod
Had summoned them to serve his golden god.

Cooper.

CONCERTO, a composition for a particular instrument, accompanied by an orchestra, more or less complete, for the purpose of showing off the ability, or rather execution of the performer.

CONCERTATO, signifies a piece of music composed in such a manner, as that all the parts may have their recitatives, be it for two, three or more voices or instruments.

CONCERTO GROSSO, a title given in the sixteenth century to symphonies with a violin principale, and other parts, obligato.

CONCH, *n. s.* } Lat. *concha*; Gr. *κογχη*.
CO'NCHEIT, *n. s.* } Conch is a sea-shell, which
CO'NCHOID, *n. s.* } is sometimes used as a trumpet. Conchite is a species of petrified shell. Conchoid is the name of a curve, so called from the resemblance to the shell of the same name. See CONCHOID.

He furnishes her closet first, and fills
The crowded shelves with rarities of shells:
Adds orient pearls, which from the *conchs* he drew,
And all the sparkling stones of various hue.

Dryden's Fables.

Nymphs, you adorn, in glossy volutes rolled,
The gaudy *conch*, with azure, green and gold.

Darum.

And how, when undecieved, the pair they bore
With sounding *conchs* and joyous shouts to shore;
How they had gladly lived and calmly died,
And why not also Torquil and his bride?

Byron. The Island.

CONCHA, in zoology, a synonyme of the mytilus and solen.

CONCHITES MARBLE, a name given by the ancients to a species of marble dug near Mezara, and remarkable for containing a great number of sea shells, and other marine bodies immersed in it.

CONCHOID, a curve invented by Nicomedes, and much used by the ancient mathematicians in the construction of solid problems; as we learn from the writings of Pappus of Alex-

andria. It is thus constructed: AP and BD,

being two straight lines intersecting each other at right angles, from P draw any number of lines P F D E, &c. on which take always $D E = D F = A B$ or $B C$; so shall the curve line drawn through the points E, E, E, be the first conchoid, or that of Nicomedes; and the curve drawn through all the other points F, F, F, is called the second conchoid, though they, in reality, be only parts of the same curve, having the same pole P, and four infinite legs, to which the line $D B D$ is a common asymptote. Newton approves of the use of the conchoid for trisecting angles, or finding two mean proportionals, and for constructing solid problems in general; because we ought either to exclude all lines besides the circle and right line out of geometry, or admit them according to the simplicity of their descriptions, in which case the conchoid yields to none except the circle.

CONCHOLOGY, (*κογχη*, a shell, and *λογος*, a discourse), the science which treats of shells, or testaceous animals. Some writers on other branches of natural history, have considered this study as too frivolous to be termed scientific; and certainly it has not been, at present, pursued with that degree of success, nor been exhibited in such close connexion with the necessary pursuits of life, as many other portions of the natural system. Conchologists have arrived at little beyond a lucid arrangement of shells; and the shapes that have been given to them in nature's bounty, or in her vagaries. The peculiarities of the animals inhabiting them, have never been sufficiently known to form the basis of any complete classification either of them, or of their bodies.

'It is not of species only that we speak,' says Mr. Donovan, 'but of whole natural families or genera, not a single species of which has been yet discovered with the animal appertaining, so little are we acquainted with the molluscous orders, or animals inhabiting the shells. Of the shells we daily see in collections few are fished up alive, the far greater number are found on shores, dead or empty. Neither, if it were otherwise, are accurate descriptions of animals, whose parts are not easily seen, or anatomical investigations, which are in many cases necessary, within the capacity of every one. Many of their parts, and their respective functions, are not to be ascertained, except by comparative analogy, and which in itself presents an insurmountable difficulty, or a field of critical enquiry so extensive and complicated that few, even with the ability to pursue it with success, could be prevailed upon to devote that attention to the subject which it requires.'

The best writers on this subject, however, have not disregarded the character and structure of

the animal, as far as they have been known. Linnæus, in particular, whose arrangement of this branch of natural history, modern authors have found it most convenient to follow, includes a description of the animal in all his general distinctions.

We should here, perhaps, at once distinguish between testaceous and crustaceous animals. In England we denominate both shell-fish: but the latter, as the crab, lobster, &c. differ from animals properly testaceous, by possessing a crust or defence upon each separate limb: whereas the former are entirely naked in particular parts, and defended only by one permanent calcareous covering. Mr. Hatched has pointed out a further distinction in the nature of their respective crusts or coverings, finding those of testaceous animals to consist only of carbonate of lime mixed with gelatinous matter, while in those of crustaceous animals the presence of phosphate of lime was detected. The echinus was the crustaceous body analysed.

Testaceous animals considered as a whole are composed, 1. Of a soft, molluscous body. 2. Of a hard calcareous shell, covering the body, and to which it is attached by certain muscles and ligaments. They are divided in the Linnæan system into univalves, bivalves, and multivalves, embracing thirty-six genera; the first two divisions being, in fact, those of Aristotle, and the last adopted from Dr. J. D. Major, a writer on this subject at the close of the seventeenth century. The genera are thus exhibited in the latest editions of the *Systema Naturæ*.

Div. I.—MULTIVALVIA.

- Gen. 1. *Chiton*.
2. *Lepas*, acorn shell.
3. *Pholas*, piddock or pierce-stone.

Div. II.—BIVALVIA.

- Gen. 4. *Mya*, Gaper.
5. *Solen*, razor or sheath-shell.
6. *Tellina*, double wedge-shell.
7. *Cardium*, cockle or heart-shell.
8. *Macra*.
9. *Donax*, Wedge-shell.
10. *Venus*.
11. *Spondylus*, spondyle.
12. *Chama*.
13. *Arca*, ark-shell.
14. *OSTREA*, oyster.
15. *Anomia*, bowl-shell.
16. *Mytilus*, muscle.
17. *Pinna*, Nacre.

Div. III.—UNIVALVIA.

i. Spira regulari cochlea.

- Gen. 18. *Argonauta*, argonaut or sailor.
19. *Nautilus*.
20. *Conus*, cone-shell.
21. *Cypræa*, gowry or cowry.
22. *Bulla*, dipper.
23. *Voluta*, rhomb-shell.
24. *Buccinum*, whelk.
25. *Strombus*, the screw.
26. *Murex*, the caltrop, or rock-shell.
27. *Trochus*, button-shell.
28. *Turbo*, whorl or wreath.

- 29. *Helix*, snail.
- 30. *Nerita*.
- 31. *Haliotis*, sea-ear.

ii. Absque spira regulari.

- 32. *Patella*, limpet.
- 33. *Dentalium*, tooth-shell.
- 34. *Serpula*, worm-shell.
- 35. *Teredo*.
- 36. *Sabella*.

Of these the inhabitants, as far as they are known, have been thus classed :

Shells.	Animals.		
1. Chiton . . .	Doris	Order MOLLUSCA.	
2. Lepas . . .	Triton		
3. Pholas	} Ascidia		
4. Mya			
5. Solen			
6. Mytilus			
7. Tellena			
8. Cardium			
9. Mactra			
10. Donax			
11. Venus			} Tethys
12. Spondylus			
13. Chama			
14. Arca			
15. Ostrea			
16. Pinna			
17. Conus			
18. Cypræa			
19. Bulla			
20. Voluta			
21. Buccinum	} Limax		
22. Strombus			
23. Murex			
24. Trochus			
25. Turbo			
26. Helix			
27. Neritas			
28. Haliotis			
29. Patella			
30. Dentalium			
31. Serpula			} Terebella
32. Teredo			
33. Sabella			
34. Argonauta			

Since the Systema Naturæ has been complete, Mullen, in his Zoology of Denmark, has considerably enlarged our acquaintance with the inhabitants of the testacea. Of his system we may offer the following synopsis.

DIV. OR FAM. I. TESTACEA UNIVALVIA.

§ I. *Testacea univalvia, testa pervalia.*

Gen. 1. *Echinus*. Testa crustacea, ano verticali, tentaculis simplicibus. 2. *Spatagus*. Testa crustacea, ano infero tentaculis penicillatis. 3. *Dentalium*. Testa calcarea, testa rude, tentaculis nullis.

§ II. *Testacea univalvia, testa patula.*

Gen. 4. *Akera*. Apertura effusa, tentaculis nullis. 5. *Argonauta*. Apertura profunda, tentaculis binis. 6. *Bulla*. Apertura repanda, tentaculis binis setaceis, colliculo extrinsecus oculatis. 7. *Buccinum*. Apertura ovata, tentaculis binis triangularibus, angulo intrinseco oculatis. 8. *Carychium*. Apertura ovata, tentaculis binis truncatis conspicuis, angulo intrinseco oculatis. 9. *Vertigo*. Apertura subquadrata, tentaculis binis sublinearibus, apice oculatis. 10. *Turbo*. Apertura orbiculari, tentaculis binis setaceis, conspicuis, angulo extrinseco oculatis. 11. *Helix*. Apertura lunari, tentaculis quatuor linearibus, apice oculatis. 12. *Planorbis*. Apertura simillunari, tentaculis binis setaceis, angulo intrinseco oculatis. 13. *Ancylus*. Apertura totali, tentaculis binis truncatis, occultis, angulo extrinseco oculatis. 14. *Patella*. Apertura totali, tentaculis binis setaceis, occulto angulo, extrinseco oculatis. 15. *Haliotis*. Apertura repanda, poris pertusa.

§ III. *Testacea univalvia, testa operculata.*

Gen. 16. *Tritonium*. Libera, apertura canaliculata, tentaculis duobus linearibus, angulo extrinseco oculatis. 17. *Trochus*. Libera, apertura sub-tetragona, tentaculis duobus, setaceis, colliculo extrinseco oculatis. 18. *Nerita*. Libera, apertura lunari, tentaculis duobus setaceis, angulo extrinseco oculatis. 19. *Valvata*. Libera, apertura circinnata, tentaculis duobus setaceis, angulo postico oculatis. 20. *Serpula*. Adnata, apertura orbiculari, tentaculis pinnatis.

DIV. OR FAM. II. TESTACEA BIVALVIA.

§ I. *Testacea bivalvia cardine dentata.*

Gen. 1. *Mya*. Testa altera extremitate hiante; cardine dente crasso solitario. 2. *Solen*. Testa utraque extremitate hiante; cardine dente reflexo, saepe gemino. 3. *Tellina*. Siphone duplici murico; cardine dentibus utrinque tribus alternis. 4. *Cardium*. Siphone duplici, cirrato, pedeque falciformi; cardine dentibus mediis alternis, remotis penetrantibus. 5. *Venus*. Siphone duplici, cirrata, pedeque laminæformi, cardine dentibus tribus approximatis, lateralibus divergentibus. 6. *Mactra*. Cardine dente medio complicato, adjacente foveola. 7. *Donax*. Cardine dentibus duobus lateraliq. solitario. 8. *Arca*. Cardine dentibus numerosis, alternis, penetrantibus. 9. *Terebratula*. Branchiis circinnatis; cardine dentibus alterius uncinatis, valvula superiore deorsum perforata.

The principal arrangements proposed before that of this great writer, were those of Lister (1685); Largius (1722); Bregnius (1732); Tournefort (1742); D'Argenville (*id*); Adanson (1757); to several of which Linnaeus, and all modern writers, have been under considerable obligations. The earliest was a noble contribution to the science of natural history, entitled, *Historia sive Synopsis Methodica Conchyliorum, folio*; containing from 1050 to 1067 plates, engraved by Dr. Lister's daughters, and published in different portions from 1685 to 1692. Dr. Lister calls it 'the basis and foundation of all good Conchology.' We do not, however, apprehend that the detail of their systems is sufficiently interesting to modern readers to occupy the large space they would require here.

§ II. *Testacea bivalvia, cardine edentulo.*

Gen. 10. *Anomia*. Branchiis simplicibus; valvula inferiore perforata. 11. *Ostrea*. Branchiis simplicibus, pede nullo; cardines fossula cava. 12. *Pecten*. Branchiis cirratis, pede juxta auriculum cardine fossula ovata byssum emittens. 13. *Mytilus*. Siphone duplici brevi; fossula lineare, byssum emittens.

DIV. or FAM. III. TESTACEA MULTIVALVIA.

Gen. 1. *Chiton*. Valvulae dorsales, tentacula nulla. 2. *Lepas*. Valvulae erectae, tentacula bipartita. 3. *Pholas*. Valvulae ad cardinem, minores.

Mr. Pennant, in his British Zoology, finished in 1777, was the first author who classed the animals of Britain according to the Linnæan arrangement. In the fourth volume of the above work he enumerates 163 species of testacea, of which he furnishes many good figures. To a new edition of this work his son has since added the recently discovered species.

Da Costa's arrangement, differing considerably, from that of Linnæus and displaying great taste and originality, is the only other modern system for which we have room. His work appeared under the title of British Conchology, 4to. 1778. It contains seventeen plates, with 123 figures of rare shells, and 'possesses,' says Dr. Turton, 'the rare, and we believe unique, excellence of giving the whole of the synonymes in the words of the respective authors themselves.' He adopts the primary division of univalves, bivalves, and multivalves, but the univalves he divides into sixteen families, which are divided into four orders.

Order I. Simple; consisting of four families.

1. Patella. 2. Haliotis. 3. Vermiculi. 4. Dentalia.

Order II. includes but one family, 5. Polythamia.

Order III. Revolved. 6. Turbinata involuta.

Order IV. Turbinate. 7. Cymbium. 8. Auris cochlea. 9. Cylindri. 10. Voluta. 11. Globosa. 12. Cassides. 13. Trochli. 14. Cochlea. 15. Buccini. 16. Murex.

II. THE BIVALVES include three orders.

Order I. With unequal valves, and shut close. Fam. 1. Pecten. 2. Spondylus. 3. Ostreum. 4. Anomia.

Order II. With equal valves, and shut close, is divided into three sections. Sect. 1. Multarticulate. Fam. 5. Pectinoides. 6. Pectunculi. 7. Arca. Sect. 2. Articulate. Fam. 8. Pectunculus. 9. Tellina. 10. Piacenta. Sect. 3. Inarticulate. Fam. 11. Margaritifera. 12. Musculus.

Order III. With valves that never shut close. Fam. 13. Chama, gapers.

III. THE MULTIVALVES contain one order. Fam. 14. Pholas. 15. Anatifera. 16. Balani.

We have noticed the important work of Dr. Lister. To complete our sketch of British conchology we may further observe that several local descriptions of shells have been given to the public from the commencement of the eighteenth century, which exhibit great clearness of conception and correctness of arrangement.

Among these are the accounts given of testaceous animals in Dr. Wallace's Description of the Orkney Islands, published in 1700; by Mr. Plot, in his History of Staffordshire and Oxfordshire; by Mr. Morton, in his Natural History of Northamptonshire; and Dr. Pulteney, in his Catalogue of the Shells of Dorsetshire, published in Hutchinson's History of that county.

In 1784 Messrs. Boys and Walker discovered many new and curious minute testacea on the shores of our island, and published a small quarto volume, entitled, Testacea Minuta rariora nuperime detecta in Arena Littoris Sandvicencis containing several beautiful microscopic species.

In 1795 Berkenhout published his Synopsis of the Natural History of Great Britain and Ireland, containing a correct list of the British testacea then known.

Mr. Donovan's work on British Shells, five volumes, was completed in the year 1804. It contains short descriptions, with well executed figures, of the different species, excluding most of the microscopic subjects. Dr. Turton characterises it as containing 'beautiful and correct colored portraits of nearly the whole of the British shells.' Of Montagu's Testacea Britannica, or a Natural History of British Shells, and Supplement, in 3 vols. 4to. with thirty plates, 1803, he says, 'To this laborious and lyncæan naturalist, who that of late has studied this elegant department of the Fauna of these islands, is not indebted for the greater part of his knowledge?' In the thirty plates and vignettes are figured about 230 species of the more rare and minute shells, all drawn and engraved under his immediate inspection, from original subjects in his own possession, and generally of his own collection. His cabinet of the natural history of the British islands is now in the British Museum.

A descriptive Catalogue of the British Testacea, by W. G. Maton, M. D. V. P. L. S. &c. and the Rev. Thomas Rackett, M. A. F. L. S. &c. in the eighth volume of the Linnæan Transactions; with six colored plates, is a valuable recent addition to the works on British conchology, as well as Mr. Wood's General Conchology, 8vo.; and Dr. Turton's own neat little volume, entitled, A Conchological Dictionary of the British Islands.

We ought not here, perhaps, to omit all notice of the arrangements that have been proposed by some celebrated modern French naturalists, among which that of Bosc, in his Histoire Naturelle des Coquilles des Vera et des Crustacées; and in the Dictionnaire d' Histoire Naturelle; and that of Lanark, in the Systeme des Animaux sans Vertèbres, are conspicuous. The last writer includes all the animals of the classes insecta and vermes of Linnæus in his system, and divides the mollusca into two orders; the first termed cephalous, from possessing a head, includes the univalves; the second, termed acephalous, from the absence of a head, includes the bivalves. An abridgment of his plan is contained in his Extrait du Cours de Zoologie, Paris, 1812.

Having thus placed the principal systems and literary history of this study before the reader, we proceed to offer a short description of the

parts of shells, as they are generally classed: following the Linnæan arrangement,

i. *The parts of multivalves*, as they are generally described, are, 1. *The valves* (valvulæ), which are said to be more or less articulated, as they seem to form one shell. 2. *The ligaments*, which are membranous substances, connecting the valves, or lining the cavities. 3. *The base*, which is the extremity, or part opposite to the apex, and is often fixed to other bodies by a tubular fleshy substance, called the peduncle. There are also, 4. *Accessory valves*, sometimes called the operculum, which close the principal entrance, or unite themselves with the primary valves, and act with them.

ii. *The parts of bivalves* are, 1. *The hinge*, upon which as a fulcrum the two sides of the shell move. In some shells this part is smooth, in others the inner surface is furnished with teeth. 2. *Beaks*, or umbones, on each side of the hinge, which are reflex, divaricate, or spiral. 3. *The ligaments*, a strong cartilaginous membrane, which connects the valves. 4. *A groove*, called a *chink*, generally situated towards the beak. 5. *The base* of bivalves, situated in the beak. 6. *The margin* of the shell which occupies the circumference of the valves, and is divided into four parts. The inferior margin, or margin of the hinge; the anterior margin, or margin next to the ligament; the posterior margin, or margin on the side of the beaks opposite the ligament. There is usually in this last a small depression, or lunule. The superior margin occupies a portion of the shell between the ligament and posterior margin. But in some species, the valves being unconnected in part, are said to have the margin gaping. 7. The valves of bivalves are divided into right and left, equal and unequal, equilateral and inequilateral, the shell being supposed to rest on its hinge, with the ligaments behind. The length of a shell is a line drawn from the beaks to the superior margin. When the longitudinal line divides the valves into two equal parts, then the shell is said to be equilateral; if into unequal parts, it is considered inequilateral. 8. *The cicatrix* is a mark on the inside of the valves, where the muscles adhered. 9. *The beard*, byssus, a collection of threads, by which some shells adhere to rocks, stones, &c.

iii. *The parts of univalves* are, 1. *The aperture*, or mouth, through which the animal protrudes itself. This is one of the principal distinctions of univalve shells, and differs very much in shape, some being bimarinate, i. e. having a lip with a double margin; bilabiate, i. e. with a double lip; gaping, the lower part of the lip distended; coarctate, i. e. straight; effuse, i. e. having the lips separated by a sinus or gutter; reflex, spreading, resupinate, &c. To the aperture belong, 2. *Labium*, the lip, or the internal margin of the aperture. This is, in respect to position, exterior, anterior, or posterior; in respect to form coarctate, digitate, disengaged, cloven, mucronate, &c. 3. *The canal*, which is the continuation or prolongation of the aperture along the beak, and forms a gutter from its commencement to the extremity. The mouth of univalves also sometimes possesses an operculum, or lid. 4. *The apex*, or summit, in a univalve shell, is

the extreme point of the spire: in bivalves it is the most elevated point of that part of the shell in which the hinge is placed. 5. *The base*, is the extremity or part opposite to the apex. In shells with a rostrum or beak, it implies the lowest part of the beak. In shells without a beak, it is the lowest part, or that which is next the aperture. 6. *The whorl*, is a wreath or convolution of the shell, sometimes bifid, at others, channelled, keeled, leafy, crowned, imbricate, lamellate, striate, lineate, &c. The contractions of the whorls are called geniculations. 7. *The spire* is a term used to describe all the whorls collectively, except the lower one, which is often called the body. The spire is a prominent feature of the univalve shell, and is either convex, crowned, capitate, or obtuse; attenuated, pointed, flattened, retuse, elevated, or depressed. 8. *The suture of the spire* is a fine spiral line, which separates the wreaths or whorls. 9. *The venter*, or belly, is the most prominent part of the body, generally situated in the vicinity of the lip, and formed by the convexity of the aperture. 10. *The umbilicus* is a circular perforation in the base of the body of many univalves. 11. *The columella*, or *pillar*, runs through the centre of the shell in the inside, from the base to the apex, in most univalve shells, and appears to be the support of the spire, and to form that part of the shell. It is either abrupt, i. e. truncate at the base; elongated, i. e. so as to project beyond the body; flat; or plated.

For the peculiarities of the inhabitants of shells, as far as they are known, see MOLLUSCA.

CONCHUCOS, a province of Peru, running along the centre of the Cordilleras. It is bounded on the north by Guamachucos, on the south by Caxatambo, east by Guamilos, and west by Huaiyllas, being of irregular shape, and very various climate. Conchucos produces fruit, grain, &c. and excellent pasture for cattle. Here are also some mines of silver, which were formerly very rich, and some washing places for gold of the standard weight of twenty-three carats.

Conchucos, a river of Peru, running south in the same province, and entering the Amazons.

CONCHYLIA, a general name for all petrified shells, as lympets, cochleæ, nautili, conchæ, lepadæ, &c.

CONCIATOR, in glass-making, is, for the crystal glass, what the founder is at the green glass-houses. He weighs and proportions the salt on ashes and sand, works them with a strong fire till they run into lumps and become white; and if the metal be too hard, and consequently brittle, he adds salt and ashes, and if too soft, sand; still mixing them to a fit temper, which is only known by the working.

CONCIERGE, old Fr. *consierge*; low. Lat. *conservius*. A palace, castle, or house, keeper. The word is used by Buck, Aubrey, and perhaps some other of our old writers; but is become obsolete. In the French language it still maintains its ground.

CONCILIABLE, old Fr. *conciliabile*. A conventicle; a small assembly. This word is now become obsolete.

Some have sought the truth in the conventicles and *conciliabiles* of heretics and sectaries. *Bacon.*

CONCILIAR, *adj.* } Lat. *concilium*. That
CONCILIARLY, *adv.* } which relates to a council; that which has been decided by a council.

Having been framed by men of primitive simplicity, in free and *conciliar* debates, without any ambitious regards. *Baker.*

CONCILIATE, *v. a.* } Lat. *concilio*. One
CONCILIATION, *n. s.* } of our etymologists,
CONCILIATING, *n.* } who finds in the Greek
CONCILIATOR, *n.* } the root of almost
CONCILIATORY, *adj.* } every English word,
CONCILIABLE, *adj.* } thus derives and defines
finer conciliate and its derivatives. 'Καλεω, καλω, voco; to call; unde concilium, concilio; to invite, or call to council; to unite in opinion, affection; also to acquire, to procure, or win favor.' His definition may be admitted, whatever may be thought of his derivation.

To the *conciliation* of sleep, it is required that there be a moderate repletion. *Gregory's Posthuma.*

It was accounted a fitre, or plants that *conciliate* affection. *Browne's Vulgar Errors.*

The very same tender, benevolent, feeling, liberal mind, which in the internal relations of life *conciliate* the genuine love of those who see men as they are rendered him an inflexible patriot. *Burke.*

In a great cause I should certainly wish, that my agent should possess *conciliating* qualities; that he should be of a frank, open, and candid disposition, soft in his nature, and of a temper to soften animosities and to win confidence. *Id.*

They would act towards them in the most *conciliatory* manner, and would talk to them in the most gentle and soothing language. *Id.*

You call these men a mob, desperate, dangerous, and ignorant; and seem to think that the only way to quiet the 'Bellua multorum capitum,' is to lop off a few of its superfluous heads. But even a mob may be better reduced to reason by a mixture of *conciliation* and firmness, than by additional irritation and redoubled penalties.

Byron. Speech on the Frame-breaking Bill.

CONCINNATE, *v. a. & adj.* } Lat. *concin-*
CONCINNITY, *n. s.* } *no, concinni-*
CONCINNOUS, *adj.* } *tos.* Concin-
nate, as a verb, means to make fit; as an adjective it signifies neat; trim; fit; compact. Concinnity is decency; fitness. Concinnous, that which is becoming; agreeable; pleasant. These words, however, are of rare occurrence in modern writers.

There a man would commend in Correggio delicateness, in Parmesano *concinnity*. *Wotton.*

CONCINATIONATOR, *n. s.* } Lat. *concio, con-*
CONCINATIONATORY, *adj.* } *cionarius*. A preacher. That which is used at public assemblies, whether religious or civil.

Their comeliness unbeguiled the vulgar of the old opinion the loyalists had formerly infused into them by their *concionatory* invectives. *Hovell.*

CONCINO CONSINI (marshal d'Ancre), of France, a court favorite, who, with his wife Leonora Galigai, accompanied Mary de' Medici, into France in 1600. He rose during the regency of that princess, to become first gentleman of the bed-chamber, governor of Normandy, and marshal of France, without ever having seen a battle.

The French nobility, however, fawned on him, and he administered all the public favors. At length the young king (Louis XIII.), influenced by his favorite Luynes, gave an order for his arrest, and the captain of the guard, Vitry, demanding his sword, as he passing the drawbridge of the Louvre, upon his hesitation, shot him dead. His body, after his funeral, we are told, was dug up by the Parisian mob, and treated with the most brutal indignity; one wretch even tore out the heart, broiled, and ate it! His wife, being brought to trial, and interrogated as to what sorcery she had employed to bewitch the queen? replied, 'That of a strong mind over a weak one.' She was executed in 1617.

CONCISE, *adj.* } Fr. *concis*; Ital. and
CONCISELY, *adv.* } Sp. *conciso*; Lat. *con-*
CONCISENESS, *n. s.* } *cisus*. Short; pithy;
CONCISION, *n. s.* } brief; compressed; broken into short periods; expressed in few words; the opposite of diffuse. Concision signifies cutting off; destroying.

Beware of dogs, beware of evil workers, beware of the *concision*. *Philippians iii. 2.*

The *concise* stile, which expresseth not enough, but leaves somewhat to be understood.

Ben Jonson's Discoveries.

Giving more scope to Mezentius and Lausus, that version which has more of the majesty of Virgil has less of his *conciseness*. *Dryden.*

Where the author is obscure, enlighten him; where he is too brief and *concise*, amplify a little, and set his notions in a fairer view. *Watts on the Mind.*

Ulysses here speaks very *concisely*, and he may seem to break abruptly into the subject.

Browne on the Odyssey.

This book, de Rerum Natura, is *concise* and methodical, and contains no very contemptible abstract of the physics which were taught in the decline of the Roman empire. *Burke.*

A man, once young, who lived retired

As hermit could have well desired,
His hours of study closed at last,
And finished his *concise* repast,
Stopped his cruise, replaced his book
Within its customary nook,
And, staff in hand, set forth to share
The sober cordial of sweet air. *Couper.*

This necessity of generally placing the accusative case after the verb is inconvenient in poetry; though it adds to the *conciseness* and simplicity of our language, as it saves the intervention of a preposition, or of a change of termination. *Darwin.*

CONCITE, *v. a.* } Fr. *conciter*; Lat.
CONCITATION, *n. s.* } *concito*. To stimulate; to urge on; to provoke. The act of stirring up. Both obsolete.

The revelations of heaven are conceived by immediate illumination of the soul; whereas the deceiving spirit, by *concentration* of humours, produces conceited phantasmes. *Browne.*

CONCITIZEN, Fr. *concitoyen*. KNOX and Stirling use this word as a synonyme for fellow-citizen.

CONCLAMATION, Lat. *conclamatio*. A simultaneous shouting, or calling out of many persons.

The Romans used *conclamation*, or a general outcry, set up at equal intervals before the corps, by persons who waited there on purpose. *Greenhill.*

CONCLAMATIO, in antiquity, a shout raised by those present at burning the dead, before they set fire to the funeral pile. The word was also applied to the signal given to the Roman soldiers to decamp, whence the expression *conclamare vasa*; and *conclamare arma*, was a signal for battle. It was likewise used for a practice of calling to a person deceased three times by his name; and, when no reply was returned, they thus expressed his decease, by 'conclatum est.' Whence the same term was afterwards applied to the cessation of the Roman empire.

CONCLAVE, *n. s.* } Fr. *conclave*; Ital. *Co'nclavista*, *n. s.* } *conclave*, *conclavi*; Sp. *conclave*; from Lat. *con* and *clavis*; because locked up. The assembly of cardinals to elect a pope; the room in which they are shut up; any private or secret assembly. Conclavist is the person who attends a cardinal during his abode in the conclave. See the next article.

I thank the holy *conclave* for their loves;
They have sent me such a man I would have
wished for. *Shakspeare.*

Still they cut their way.
Till to the bottom of hell's palace diving,
They enter Dis' deep *conclave*. *P. Fletcher.*

The great seraphick lords and cherubim
In close recess and secret *conclave* sat. *Milton.*

It was said of a cardinal, by reason of his apparent likelihood to step into St. Peter's chair, that in two *conclaves* he went in pope and came out again cardinal. *South's Sermons.*

Forthwith a *conclave* of the godhead meets,
Where Juno in the shining senate sits. *Garth.*

To the vestry indignant, he then stalked away.
Where churchwardens and sidesmen sat ranged in array,
And so grim did he look that their *conclave* astounded
Thought they saw Hamlet's ghost, or Don Quixote
dismounted. *Huddesford.*

CONCLAVE, the place in which the cardinals meet for the despatch of public business. The *conclave* is in the pontifical palace of the Vatican, and consists of a suite of grand halls or corridors, with rows of cells formed on each side of equal dimensions, being five feet long and four wide. Two are allotted to each cardinal; one for his eminence, and the other for his officer, called the *conclavist*, and his *valet de chambre*. They are all painted green, except those of the cardinals who were created by the deceased pope, whose cells are painted violet color, and the insides are lined with serge of the same color. On the election of a pope, the cardinals, after having heard all the bulls read which relate to the subject, the manner of living in *conclave*, &c. which they are all sworn to observe, are then kept in close *conclave* till they have decided upon which cardinal the election has fallen. The *conclave* is very strictly guarded by troops: neither the cardinals, nor any person shut up in it, are spoken to but at certain hours, even the provisions are examined, lest any letters should be conveyed from the ministers of foreign powers, or others, who might have an interest in influencing the issue of the election.

CONCLU'DE, *v. a. & v. n.* } Fr. *conclure*;
CONCLU'DENCY, *n. s.* } Ital. *concludere*;
CONCLU'DENT, *adj.* } Span. *concluir*;
CONCLU'DER, *n. s.* } Lat. *concludere*;
CONCLU'DINGLY, *adv.* } from *con* and *clu-*
CONCLU'SIBLE, *adj.* } *dere*. To shut up;
CONCLU'SION, *n. s.* } to bring to a close;
CONCLU'SIONAL, *adj.* } to place beyond
CONCLU'SIVE, *adj.* } the reach of fur-
CONCLU'SIVELY, *adv.* } ther change; to
CONCLU'SIVENESS, *n. s.* } draw to a decisive
point; to comprehend in; to terminate; are the ideas conveyed by this whole class of words. The various shades of meaning will be rendered obvious by the authorities quoted below.

God hath *concluded* them all in unbelief, that he might have mercy upon all. *Romans xi. 32.*

Let us hear the *conclusion* of the whole matter: Fear God and keep his commandments; for this is the whole duty of man. *Eccles. xii. 13.*

Unto a tent prince and princes
Me thought brought me and my maistres,
And said we werin at full age
There to *conclude* our marriage. *Chaucer.*
For whan that he himself *concluded* had,
Him thought eche other mannes wit so bad,
That impossible it were to repleie
Again his chois: this was his fantasie

Id. Cant. Tales.

And shortly to *concluden*, swiche a place
Was never in erthe in so litel a space. *Id.*

For many times when she wold make
A full gode syllogisme, I drude
That afterward there shall in dede
Folowe an ill *conclusion*.

Id. Romaunt of the Rose.

Ways of peaceable *conclusion* there are but those two certain; the one a sentence of judicial decision, given by authority thereto appointed within ourselves; the other, the like kind of sentence given by a more universal authority. *Hooker.*

The very person of Christ, therefore, for ever and the self-same, was only, touching bodily substance, *concluded* within the grave. *Id.*

They humbly sue unto your excellence,
To have a goodly peace *concluded* of
Between the realms of England and of France. *Shakspeare.*

Is it *concluded* he shall be protector?
It is determined, not *concluded* yet;
But so it must be, if the king miscarry.

Id. Richard III.

Her physician tell me,
She has pursued *conclusions* infinite
Of easy ways to die.

Id. Antony and Cleopatra.

The king would never endure that the base multitude should frustrate the authority of the parliament, wherein their votes and consents were *concluded*.

Bacon's Henry VII.

This I speak only to desire Enpolis not to speak peremptorily, or *conclusively*, touching the point of possibility, till they have heard me deduce the means of the execution. *Bacon.*

For why should we the busy soul believe,
When boldly she *concludes* of that and this,

When of herself she can no judgment give,
Nor how, nor whence, nor where, nor what she is. *Darce.*

Thus doth the wit, admitting all for true,
Build fond *conclusions* on those idle grounds. *Id.*

I can speak no longer; yet I will strain myself to breathe out this one invocation, which shall be my *conclusion*. *Howel*.

Judgment concerning things to be known, or the neglect and *concludency* of them, ends in decision. *Hale*.

Consideration of things to be known, of their several weights, *conclusiveness*, or evidence. *Id. Origin of Mankind*.

Though these kind of arguments may seem more obscure, yet, upon a due consideration of them, they are highly consequential and *concludent* to my purpose. *Id.*

Examine whether the opinion you meet with, repugnant to what you were formerly embued with, be *concludingly* demonstrated or not. *Digby*.

The last dictate of the understanding is not always absolute in itself, nor *conclusive* to the will, yet it produces no antecedent nor external necessity. *Branhall's Answer to Hobbes*.

'Tis as certainly *conclusive* from God's prescience, that they will voluntarily do this, as that they will do it all. *Hammond*.

Those that are not men of art, not knowing the true forms of syllogism, cannot know whether they are made in right and *conclusive* modes and figures. *Locke*.

If the consent of the majority shall not, in reason, be received as the act of the whole, and *conclude* every individual, nothing but the consent of every individual can make any thing to be the act of the whole: but such a consent is next to impossible ever to be had, if we consider the infirmities of health, and avocations of business, which in a number, though much less than that of a commonwealth, will necessarily keep many away from the public assembly. *Id.*

Youth, ere it sees the world, here studies rest; And age, returning thence, *concludes* it best. *Dryden*.

These are my theme, and how the war began, And how *concluded* by the godlike man. *Id. Æneid*.

And all around wore nuptial bonds, the ties Of love's assurance, and a train of lies, That, made in lust, *conclude* in perjuries. *Id. Fables*.

The providences of God are promiscuously administered in this world; so that no man can *conclude* God's love or hatred to any person, by any thing that befalls him. *Tillotson*.

Can we *conclude* upon Luther's instability as our author has done, because, in a single notion, no way fundamental, an enemy writes that he had some doubtings? *Atterbury*.

There is something infamous in the very attempt: the world will *conclude* I had a guilty conscience. *Arbutnot's History of John Bull*.

He granted him both the major and the minor; but denied him the *conclusion*. *Addison's Frecholder*.

I have been reasoning, and, in *conclusion*, have thought it best to return to what fortune hath made my home. *Swift*.

It might furnish matter *conclusive* in argument, and instructive in policy: but with all due submission to high authority, and with all decent deference to superior lights, it does not seem quite clear to a discernment no better than mine, that the premises in that piece conduct irresistibly to the *conclusion*. *Bahe*.

Give me the lonely valley,

The dewy eve, and rising moon

Fair beaming, and streaming,

Her silver light the boughs among;

While falling, recalling,

The amorous thrush *concludes* his sang. *Burris*.

Hence he *concludes* that the hot air at the bottom of the Andes becomes temperate by its own rarefaction when it ascends to the city of Quito. *Darwin*.

Calm and alternate storm, moisture and drought, Invigorate by turns the springs of life In all that live, plant, animal, and man, And in *conclusion* mar them. *Cowper*.

His friends, who found he fled the town, *Concluded* him a farmer grown; And called him, in derision pleasant, Laertes, or the new-made peasant. *Sheridan*.

CONCOAGULATE, *v. a.* } Fr. *coaguler*;
CONCOAGULATION, *n. s.* } Lat. *coagulatus*.
To curdle or congeal one thing with another. The coagulating together of different bodies.

The saline parts of those, upon their solution by the rain, may work upon those other substances, formerly *concoagulated* with them. *Boyle's Experiments*.

They do but coagulate themselves, with *concoagulating* with them any water. *Id. History of Firmness*.

CONCOCT, *v. a.* } Lat. *con* and *coquere*
CONCOCTES, *n. s.* } To convert food into nu-
CONCOCTION, *n. s.* } triment by the stomach;
CONCOCTIVE, *adj.* } to perfect or sublime by heat; to bring to maturity or ripeness. Concoction is the act of so doing. Concoctive is that which possesses the power of performing those operations.

The maister cooke was call'd *Concoction*, A careful man, and full of comely guise.

Spenser's Faerie Queene.

The working of purging medicines cometh two or three hours after the medicines taken; for that the stomach first maketh a proof, whether it can *concoct* them. *Bacon*.

The root which continueth ever in the earth, is still *concocted* by the earth; and fruits and grains are half a year in *concocting*, whereas leaves are out and perfect in a month. *Id.*

This hard rolling is between *concoction* and a simple maturation. *Id. Natural History*.

He, though he knew not which soul spake, Because both meant, both spake the same,

Might thence a new *concoction* take, And part far purer than he came. *Donne*.

Assuredly he was a man of a feeble stomach, unable to *concoct* any great fortune, prosperous or adverse. *Hayward*.

Errors in education should be less indulged than any: these, like faults in the first *concoction*, that are never mended in the second or third, carry their afterwards incorrigible taint with them through all the parts and stations in life. *Locke*.

The vital functions are performed by general and constant laws; the food is *concocted*, the heart beats, the blood circulates, the lungs play. *Cheyne's Philosophical Principles*.

The notions and sentiments of others' judgment, as well as of our own memory, makes our property: it does, as it were, *concoct* our intellectual food, and turns it into a part of ourselves. *Watts on the Mind*.

The small close-lurking minister of fate, Whose high *concocted* venom through the veins A rapid lightning darts. *Thomson's Summer*.

Past indiscretion is a venial crime, And if the youth, uncollowed yet by time, Bore on his branch, luxuriant then and rude, Fruits of a blighted size, austere and crude, Maturer years shall happier stores produce, And meliorate the well *concocted* juice. *Cowper*

CONCOLOUR, *adj.* Lat. *concolor*. Of one color; without variety.

In *concolour* animals, and such as are confined unto the same colour, we measure not their beauty thereby; for if a crow or blackbird grow white we account it more pretty.

CONCOMITATE, *v. a.*
CONCOMITANT, *n. s. & adj.*
CONCOMITANCE, *n. s.*
CONCOMITANCY, *n. s.*
CONCOMITANTLY, *adv.*
CONCOMITATION, *n. s.*

Lat. *con*, and *comitans*. The verb, which is unusual, signifies to be connected with anything collaterally; to come and go with it. Subsisting in concurrence with another thing, is denoted by concomitance and concomitancy. A concomitant is a person or thing which is collaterally connected with another.

The simple bloody spectation of the lungs, is differentiated from that which *concomitates* a pleurisy.

Harvey on Consumption.
 In consumptions, the preternatural *concomitants*, an universal heat of the body, a torminous diarrhoea, and hot distillations, have all a corrosive quality. *Id.*

The spirit that furthereth the extension or dilatation of bodies, and is ever *concomitant* with porosity and dryness. *Bacon.*

He made him the chief *concomitant* of his heir apparent and only son, in a journey of much adventure. *Watt n.*

The secondary action subsisteth not alone, but in *concomitancy* with the other; so the nostrils are useful for respiration and smelling, but the principal use is smelling. *Brown.*

To argue from a *concomitancy* to a causality, is not infallibly conclusive. *Glauville's Scepis.*

The other *concomitant* of ingratitude is hard-heartedness, or want of compassion. *South's Sermons.*

It has, therefore, pleased our wise Creator, to annex to several objects, and the ideas which we receive from them, as also to several of our thoughts, a *concomitant* pleasure, and that in several objects, to several degrees; that those faculties which he had endowed us with, might not remain wholly idle and unemployed by us. *Locke.*

And for tobacco, who could bear it?
 Filthy *concomitant* of claret! *Prior.*

Reproach is a *concomitant* to greatness, as satires and invectives were an essential part of a Roman triumph. *Addison.*

Horror stalks around,
 Wild staring, and his sad *concomitant*
 Despair, of abject look. *Philips.*

Where antecedents, *concomitants*, and consequents, causes and effects, signs and things signified, subjects and adjuncts, are necessarily connected with each other, we may infer. *Watts.*

The coloured fluid was carried to the extremities of the leaf by vessels most conspicuous on the upper surface, and there changed into a milky fluid, which is the blood of the plant, and then returned by *concomitant* veins on the under surface. *Darwin.*

CONCORD, *v. n. & n. s.*
CONCORDABLE, *adj.*
CONCORDANT, *n. s. & adj.*
CONCORDANTLY, *adv.*
CONCORDANCE, *n.*
CONCORDANCY, *n.*
CONCORDLY, *adv.*

The noun is of perpetual recurrence. It denotes peace; union; acting harmoniously together; suitableness; agreement between persons and things; harmonious combination of sounds; the principal grammatical relation of one word to

another, distinct from regimen. The words derived from it do not require definition, with the exception of concordance, and concordate; the former of which, in addition to its obvious sense, has also that of a grammatical concord, and of a book, showing in how many texts of Scripture any word occurs; while concordate means a compact, a convention.

What *concord* hath Christ with Belial?
 2 Cor. vi. 15.

Now cometh the snine of hem that maken discord among folke, which is a sin that Crist hateth utterly; and no wonder is, for he died for to make *concord*.
Chaucer's Cant. Tales.

But lovely *concord* and most sacred peace
 Doth nourish virtue, and fast friendship breeds;
 Weake she makes strong, and strong things doth increase,
 Till it the pitch of highest praise exceeds.

Spenser's Faerie Queene.
 After three *concordances* learned, let the master read unto him the epistles of Cicero.

Ascham's Schoolmaster.
 Had I power, I should
 Pour the sweet mi'k of *concord* into hell,
 Uproar the universal peace.

Shakspeare. Macbeth.
 The man who hath not music in himself,
 Nor is not moved with *concord* of sweet sounds,
 Is fit for treason. *Id. Merchant of Venice.*
 The richest jewel in all the heavenly treasure,
 That ever yet unto the earth was shown,
 Is perfect *concord*, the only perfect pleasure
 That wretched earth-born men have ever known,
 For many hearts it doth compound in one.

Darley.
 It appeareth by the *concord* made between Henry and Roderick the Irish king. *Id. On Ireland.*

Unsafe within the wind
 Of such commotion; such as, to set forth
 Great things by small, if nature's *concord* broke,
 Among the constellations war were sprung. *Milton.*
 Were every one employed in points *concordant* to their natures, professions, and arts, commonwealths would rise up of themselves. *Brown's Vulgar Errors.*
 Have those who have writ about declensions, *concord*s, and syntaxes, lost their labour? *Locke.*

Some of you turn over a *concordance*, and there having the principal word, introduce as much of the verse as will serve your turn. *Swift.*

How comes he to number the want of synods in the Gallican church among the grievances of that *concordate*, and as a mark of their slavery, since he reckons all convocations of the clergy in England to be useless and dangerous? *Id.*

His abilities, industry, and influence, were employed without interruption to the last hour of his life, to give stability to the liberties of his country; security to its landed property; increase to its commerce; independence to its public councils; and *concord* to its empire. *Burle.*

So to the sacred sun in Memnon's fane,
 Spontaneous *concord*s quire the matins strain;
 Touched by his orient beam, responsive rings
 The living lyre, and vibrates all its strings.

Darwin.
 So when with light and shade, *concordant* strife¹
 Stern Clotho weaves the chequered thread of life,
 Hour after hour the growing line extends,
 The cradle and the coffin bound its ends. *Id.*

What one fine stimulated sense discerns,
 Another sense by imitation learns—
 So in the graceful dance the step sublime,
 Learns from the ear the *concordance* of time. *Id.*
CONCORD, in grammar, that part of syntax,

or construction, by the rules of which nouns are put in the same gender, number, and case; and verbs in the same number and person with nouns and pronouns. See GRAMMAR.

CONCORD, in music, the relation of two sounds that are always agreeable to the ear, whether applied in succession or consonance.

CONCORD, a large and flourishing post town of Massachusetts, situated on the river Concord, in a healthy and pleasant spot, nearly in the centre of Middlesex county, eighteen miles north-west of Boston, and seventeen east of Lancaster. Its Indian name was Musquetequid; and it owes its present designation to the peaceable manner in which it was obtained from the natives. The first settlers having fairly purchased the spot, before they obtained an act of incorporation. This was on September 3rd, 1635; and they are said never to have had any contest with the Indians. For thirteen years previous to 1791, the average number of deaths was seventeen; one in four of whom was seventy years old and upwards. The public buildings are very respectable. Over the river are three convenient bridges, one of which is 208 feet long, and eighteen feet wide, supported by twelve piers built after the manner of that over the Charles. This town is famous in the history of the revolution, having been the seat of the provincial congress in 1774, and the spot where the first opposition was made to the British troops on the memorable 19th of April, 1775. The general court frequently held their sessions here when contagious diseases prevailed in the capital. It is 357 miles north-east of Philadelphia.

CONCORD, a flourishing post town of New Hampshire, is pleasantly situated on the west bank of the Merrimack, in Rockingham county, eight miles above Hookset falls. The legislature have often held their sessions here; and much of the trade of the upper country centers in it. A handsome toll bridge across the Merrimack, connects this town with Pembroke. Its Indian name was Penacook. It is fifty-five miles W. N.W. of Portsmouth, fifty-eight south-west of Dartmouth College, and seventy north from Boston.

CONCORD, FORM OR, in ecclesiastical history, a standard book among the Lutherans, composed at Torgaw, in 1576, and thence called the book of Torgaw. It was reviewed at Burg, by six Lutheran doctors of Germany, the principal of whom was James Andree. It was first imposed on the Saxons by Augustus, and occasioned great opposition. The dispute was revived in Switzerland in 1718, when the magistrates of Bern published an order for adopting it as the rule of faith; the consequence of which was a contest, that reduced its credit and authority.

CONCORDANCE is a term that has generally been restricted to dictionaries or indexes of the Bible, wherein all the leading words are ranged alphabetically; and the books, chapters, and verses wherein they occur referred to. Cardinal Hugo de St. Charo is said to have employed 500 monks at once in compiling a Latin concordance. There are various concordances in that language; one, in particular, called the Concordance of England, compiled by J. Darling-

ton, of the order of Predicants; another, more accurate, by the Jesuit Zamora. In 1523 Rabbi Mordecai Nathan first published a Hebrew concordance, at Venice; but the best and most useful Hebrew concordance is that of Buxtorf, printed at Basil, in 1632. Calasius has given us concordances of the Hebrew, Latin, and Greek, in two columns: the first, which is Hebrew, is that of Rabbi Mordecai Nathan, verbatim, and according to the order of the books and chapters; in the other column is a Latin interpretation of each passage of scripture quoted by Rabbi Mordecai; this interpretation is Calasius's own; but in the margin he adds that of the LXX. and the Vulgate, when different from his. The work is in four volumes, folio, Rome, 1621.

Dr. John Taylor published, in 1754, a Hebrew concordance, in two volumes, folio, adapted to the English Bible, and disposed after the manner of Buxtorf. The Greek concordances are only for the New Testament; except one by Conrad Kircher, on the old, containing all the Hebrew words in alphabetical order; and underneath all the interpretations of them in the LXX., and, in each interpretation, all the places where they occur in that version. In 1718 Trommius published his Greek concordance for the LXX., at Amsterdam, in two volumes, folio; and Schmidius, improving on a similar work of H. Stephen, has given an excellent Greek concordance for the New Testament, the best edition of which is that of Leipsic, anno 1717. We have several very copious concordances in English, as Newmann's Butterworth's, &c. but the last, and best esteemed, is that by Alexander Cruden, M. A.

CONCORDANT VERSES, such as have several words in common; but which, by the addition of other words, convey a different meaning. Such are these:

Et canis in silva venatur, et omnia servat.

Et lupus in silva nutritur, et omnia vastat.

CONCORDIA, in ancient geography, a town of Lusitania, on the Tagus, north-west of Trajan's bridge, mentioned by Ptolemy. 2. A town of the Nemetes, in Belgica, on the west side of the Rhine; a Roman fortress, situated between Brocomagus, and Noviomagus; now called Drusenheim. 3. A town of the Veneti, situated at the confluence of the rivers Romatinus Major and Minor, thirty-one miles west of Aquileia. It was a Roman colony, and surnamed Julia, but destroyed by Attila. It is still called Concordia, and though ruinous is the see of a bishop. It lies in the province of Friuli, and ci-devant territories of Venice, ceded to the emperor, by the French, in 1797.

CONCORDIA, in the Roman polytheism, the goddess of concord. She had temples on the declivity of the capitol, in the portico of Livia, and on Mount Palatine. This last was built of brass by Cneius Flavius, on reconciling the senate and people. She was drawn with a cup in her right hand, and in her left a sceptre or cornucopiae. Her symbols were two hands joined, as is seen in coins of Nero and Aurelius Verus: also two serpents twisting about a caduceus.

CONCORPORATE, *v. a. & v. n.* } Lat. *con*
CONCORPORATION, *n. s.* } and *corpus.*

To unite into one mass or substance. The union thus produced.

When we *concorporate* the sign with the signification, we conjoin the word with the spirit.

Taylor's Worshy Communicant.

Thus we chastise the god of wine

With water that is feminine,

Until the cooler nymph abate

His wrath, and so *concorporate*.

Cleaveland.

Concorporation with the mundane spright. *Morc.*

CONCOURSE, *n. s.* Fr. *concorso*; Ital. *concorso*; Span. *concurso*; Lat. *concursum*. Many persons or things congregated together; the congregating of numerous persons or things; the point at which two bodies join or intersect.

Do all the nightly guards,

The city's watches, with the people's fears,

The *concourse* of all good men strike thee nothing?

Ben Jonson.

The coalition of the good frame of the universe was not the product of chance, or fortuitous *concourse* of particles of matter. *Hale's Origin of Mankind.*

The prince with wonder hears, from every part,

The noise and busy *concourse* of the mart.

Dryden's Virgil.

So soon as the upper glass is laid upon the lower, so as to touch it at one end, and to touch the drop at the other end, making with the lower glass an angle of about ten or fifteen minutes; the drop will begin to move towards the *concourse* of the glasses, and will continue to move with an accelerated motion, till it arrives at that *concourse* of the glasses. *Newton.*

But why should I his childish feats display?

Concourse, and noise, and toil, he ever fled;

Nor cared to mingle in the clamorous fray

Of squabbling imps.

Battie.

CONCRE'ATE, *v. a.* old Fr. *concreer*; Lat. *con* and *creo*. To create simultaneously.

Upon loving God above all, and our neighbour as ourselves, hang all the law and all the gospel. And this, as a rule *concreated* with man, is that which the apostle calls the royal law; which if we fulfil, we do well. *Feltham.*

CONCRE'DIT. Lat. *concredo*. To entrust with; to confide to the keeping of.

Hath the most celestial and important matters *concredited* to him. *Barrow.*

CONCREMATION. Lat. *concremo*. The burning of several things together.

CONCRETE, *v. a. & n.*

CO'NCRETE, *n. s. & adj.*

CONCRE'TELY, *adv.*

CONCRI'TENESS, *n. s.*

CONCRE'TION, *n. s.*

CO'NCRE'TIVE, *adj.*

CO'NCRE'TIVELY, *adv.*

CO'NCRE'MENT,

CONCRE'SCENCE, *n. s.*

CONCRE'TURE, *n. s.*

Fr. *concret*; Ital. and Sp. *concreto*; Lat. *concretus*. To concrete is to unite into one mass; to coalesce; to harden into a solid substance. *Concretion* is the act of the concrete

power in forming this union; and likewise the mass. *Concrete*, *concrement*, or *concreture*, so formed. In logic, *concrete* is opposed to abstract, and *concretely* to abstractly. *Concreescence* is the act or quality of being concreted.

A kind of mutual commutation there is, whereby those *concrete* names, God and man, when we speak of Christ, do take interchangeably one another's room; so that, for truth of speech, it skilleth not whether we say that the son of God hath created the world, and the son of man by his death hath saved it; or else that the son of man did create, and the son of God died to save the world. *Hooker.*

Seeing it is neither a substance perfect, nor inchoate, how any other substance should thence take *concreescence*, hath not been taught.

Raleigh's History of the World.

Some plants, upon the top of the sea, are supposed to grow of some *concretion* of slime from the water, where the sea stirreth little.

Bacon's Natural History.

When wood and other bodies petrify, we do not ascribe their induration to cold, but unto salinuous spirit, or *concretive* juices. *Boerhaave's Vulgar Errors.*

That there are in our inferior world divers bodies, that are *concreted* out of others, is beyond all dispute; we see it in the meteors. *Hale's Origin of Mankind.*

There is the cohesion of the matter into a more loose consistency, like clay, and thereby it is prepared to the *concrement* of a pebble or flint. *Id.*

The first *concrete* state, or consistent surface of the chaos, must be of the same figure as the last liquid state. *Burnet.*

Sin, considered not abstractedly for the mere act of obliquity, but *concretely*, with such a special dependence of it upon the will as serves to render the agent guilty. *Norris.*

Heat, in general, doth not resolve and attenuate the juices of a human body: for too great heat will produce *concretions*. *Arbuthnot on Aliments.*

If gold itself be admitted, as it must be, for a porous *concrete*, the proportion of void to body, in the texture of common air, will be so much the greater.

Bentley's Sermons.

Concrete terms, while they express the quality do also either express, or imply, or refer to some subject to which it belongs; as white, round, long, broad, wise, mortal, living, dead: but these are not always noun adjectives, in a grammatical sense; for a knave, a fool, a philosopher, and many other *concretes*, are substantives, as well as knavery, folly, and philosophy, which are the abstract terms that belong to them. *Watts's Logick.*

It is shrunk into the polished littleness of modern elegance and personal accommodation: it has evaporated from the gross *concrete* into an essence and rectified spirit of expense, where you have tuns of ancient pomp in a vial of modern luxury. *Burke.*

The impatient Senses, goaded to contract, Forge new ideas, changing as they act; And, in long streams dissevered, or *concrete* In countless tribes, the fleeting forms repeat. *Darwin.*

Many are the opinions both of ancient and modern writers concerning the production of pearls. Mr. Roaumur thinks they are formed like the hard *concretions* in many land animals, as stones of the bladder, gall stones, and bezoar, and hence concludes them to be a disease of the fish. *Id.*

CONCRETE, in natural philosophy and chemistry, signifies a body made up of different principles, or any mixed body: thus soap is a factitious *concrete*, mixed together by art; and antimony is a natural *concrete*, or a mixed body compounded in the bowels of the earth.

CONCRE'W. Lat. *concreasco*. To grow entangled. I know of no other authority but Spenser for this word; and he seems to have coined it for the sake of a rhyme. He says, of the squire of prince Arthur, that his locks, which were wont 'to sweat out dainty dew, he let to grow and griesly to concrew.'

CO'NCUBINE, *n. s.*
 CONCU'BINACY, *n. s.*
 CONCU'BINATE, *n. s.*
 CONCU'BINAGE, *n. s.*
 CONCU'BINARY, *n. s. & adj.*

Fr. *concubine*;
 Ital. Span. and
 Lat. *concubina*;
 from *con* and
cumbere. A fe-
 male who lives as a wife with a man, without
 being married to him. The state of being a con-
 cubine.

He wolde suffre for a quart of wine,
 A good felaw to have his *concubine*
 A twelvemonth, and excuse him at the full.

Chaucer. Cant. Tales.

I know I am too mean to be your queen,
 And yet too good to be your *concubine*.

Shakespeare. Henry VI.

When his great friend was suitor to him to pardon
 an offender, he denied him: afterwards, when a
concubine of his made the same suit, he granted it to
 her; and said, Such suits were to be granted to
 whores.

Bacon.

Or like some strange disguised Messaline,
 Hires a night's lodging of his *concubine*.

Hall.

He caused him to paint one of his *concubines*, Cam-
 paspe, who had the greatest share in his affection.

Dryden.

The wife, though a bright goddess, thus gives
 place

To mortal *concubines* of fresh embrace.

Granville.

Adultery was punished with death by the ancient
 heathens: *concubinage* was permitted.

Broome.

CONCUBINAGE, in the Roman law, was called
licita consuetudo, an allowed custom. This ex-
 pression, in the constitutions of the Christian
 emperors, signifies what we now call a marriage
 in conscience. Inheritances descended to chil-
 dren, which sprung from such a tolerated co-
 habitation. This concubinage they looked on as a
 kind of marriage, and even allowed it several
 privileges; but it was confined to a single per-
 son, and was of perpetual obligation as much as
 marriage itself. Hottoman observes, that the
 Roman laws had allowed of concubinage long
 before Julius Cæsar made that law, whereby
 every one was allowed to marry as many wives
 as he pleased. Valentinian allowed every man
 two. Cujas observes, that the ancient laws
 allowed a man to espouse, under the title of
concubine, persons esteemed unequal to him, on
 account of the want of some qualities requisite
 to sustain the full honor of marriage. Though
concubinage was beneath marriage, both as to
 dignity and civil effects; yet *concubine* was a
 reputable title, very different from that of mis-
 tress among us. The commerce was esteemed
 so lawful that the *concubine* might be accused of
 adultery in the same manner as a wife. This
 kind of concubinage is still in use in some coun-
 tries, particularly in Germany, under the title of
 half marriage, morgengabic marriage, or mar-
 riage with the left hand; alluding to the manner
 of its being contracted, viz. by the man's giving
 the woman his left hand instead of his right.
 The children are not reputed either legitimate or
 bastards, but natural children, and capable only
 of donations. They retain the low rank of the
 mother; and are on this ground disqualified for
 inheriting the effects of the father.

CONCU'LCATE, *v. a. 2*
 CONCU'LCATION, *n. s.*

Fr. *conculquer*;
 Ital. *conculcare*; Sp.

conculcar; Lat. *conculcare*. To tread down; to
 tread under foot; to lay waste.

Conculcating and trampling under foot whatsoever
 is named of God.

Montagu.

CONCU'PISCENCE, *n. s.*
 CONCU'PISCENT, *adj.*
 CONCU'PISCENTIAL, *adj.*
 CONCU'PISCIBLE, *adj.*

Fr. *concupis-
 cence*; Ital. *con-
 cupiscenza*; Sp.
concupiscencia;

Lat. *concupiscere*. An eager, earnest desire; a
 longing for; coveting after; libidinous desire;
 lechery. *Concupiscible* signifies exciting de-
 sire; eager to gain anything.

This *concupiscence*, when it is wrongfully disposed
 or ordained in man, it maketh him covet by covetise
 of flesh, fleshly sinne by sight of his eyen, as to erth-
 ly things, and also covetise of highnesse by pride of
 hearte.

Chaucer. Cant. Tales.

What thinge is the plesure of swetnesse,

And most bitter in final succession?

Or what thing giveth man occasion

In tender age to be *concupiscent*?

Chaucer.

Of just Davide by perfitte penitence,

Where rulers may see in a myrrour clear,

The bytter fruite of false *concupiscence*,

How Jewry bought Uria's death ful deare.

Earl of Surrey.

We know even secret *concupiscence* to be sin; and
 are made fearful to offend, though it be but in a
 wandering cogitation.

Hooker.

He would not, but by gift of my chaste body

To his *concupiscent* intemperate lust,

Release my brother. *Shakespeare. Measure for Measure*

In our faces the evident signs

Of foul *concupiscence*; whence evil store,

Even shame, the last of evils.

Milton's Paradise Lost.

The schools reduce all the passions to these two
 heads, the *concupiscible* and irascible appetites.

South's Sermons.

What then!—are appetites and lusts laid down

With the same ease that man puts on his gown?

Will avarice and *concupiscence* give place,

Charmed by the sounds—Your Reverence or your
 Grace?

Cowper.

CONCU'R, *v. n.*

CONCU'RRENCE, *n. s.*

CONCU'RRENCY, *n. s.*

CONCU'RRENT, *n. & adj.*

CONCU'RRENTLY, *adv.*

CONCU'RSIONS, *n. s.*

Fr. *concourir*;
 Ital. *concurrere*;
 Span. *concurrir*;
 Lat. *concurrere*. The
 meaning which the
 CONCU'RSIONS, *n. s.*
 Latin root has, is

easily to be discovered in all the modern deriva-
 tives from it. Conjoint action is always ex-
 pressed or implied. To *concur*, therefore, sig-
 nifies to unite in one point; to agree in opinion
 or actions; to be in unison with; to be a joint
 contributor to any effect or event. *Concur* takes
to before the effects to which the agent contri-
 butes; and *with* before the person with whom
 the agent agrees. The secondary follow closely
 the sense of the primary words.

It is not evil simply to *concur* with the heathens,
 either in opinion or action; and that conformity with
 them is only then a disgrace, when we follow them
 in that they do amiss, or generally in that they do
 without reason.

Hooker.

Their *concurrance* in persuasion, about some mate-
 rial points belonging to the same polity, is not strange.

Id. Preface.

There is no difference between the *concurrent* echo
 and the iterant, but the quickness or slowness of the
 return.

Bacon.

I conjoin with these laws the personal presence of the king's son, as a *concurrent* cause of this reformation.
Davies on Ireland.

Struck with these great *concurrences* of things.

Crashaw.

For, without the *concurrent* consent of all these three parts of the legislature, no such law is, or can be made.

Hale.

The *concurrence* of the peers in that fury, can be imputed to the irreverence the judges were in.

Clarendon.

Their affections were known to *concur* with the most desperate counsels.

Id.

To have an orthodox belief, and a true profession, *concurring* with a bad life, is only to deny Christ with a greater solemnity.

South.

To all affairs of importance there are three necessary *concurrents*, without which they can never be dispatched; time, industry, and faculties.

Decay of Piety.

We have no other measure but our own ideas, with the *concurrence* of other probable reasons, to persuade us.

Locke.

Though reason favour them, yet sense can hardly allow them; and, to satisfy, both these must *concur*.

Temple.

All combined

Your beauty, and my impotence of mind;
And his *concurrent* flame, that blew my fire;
For still our kindred souls had one desire.

Dryden's Fables.

When outward causes *concur*, the idle are soonest seized by this infection.

Collier on the Spleen.

Extremes in nature equal good produce,

Extremes in man *concur* to general use.

Pope.

He views our behaviour in every *concurrence* of affairs, and sees us engage in all the possibilities of action.

Addison's Spectator.

Acts which shall be done by the greater part of my executors, shall be as valid and effectual as if all my executors had *concurred* in the same.

Swift's Last Will.

A bishop might have officers, if there was a *concurrence* of jurisdiction between him and the archdeacon.

Ayliffe.

Their omnifarious *concursions*, and combinations, and coalitions.

Bentley.

Governments of all kinds are administered only by men; and great mistakes, tending to inflame these discontents, may *concur*.

Burke.

He far exceeded all other statesmen in the art of drawing together, without the seduction of self-interest, the *concurrence* and co-operation of various dispositions and abilities of men, whom he assimilated to his character and associated in his labours.

Id.

CONCUS'S, *v. n.*

CONCUSSATION, *n. s.*

CONCUS'SION, *n. s.*

CONCUS'SIVE, *adj.*

Lat. *concutio*; *con-*
cusso. The verb is of
rare occurrence, and
appears to be now dis-

used. Daniel, the poet, says, 'concusSED with uncertainty.' Concussation, which denotes violent agitation, or shaking, is also not frequent. Concussion signifies the act of shaking abruptly and violently; the state of being so shaken. A concussive power is possessed by the agent who performs the act.

It is believed that great ringing of bells, in populous cities, hath dissipated pestilent air; which may be from the *concussion* of the air.

Bacon's Natural History.

There want not instances of such an universal *concussion* of the whole globe, as must needs imply an agitation of the whole abyss.

Woodward's Natural History.

The strong *concussion* of the heaving tide
Roll'd back the vessel to the island's side.

Pope's Odyssey.

The vast structure of superstition and tyranny, which had been for ages in rearing, and which was combined with the interest of the great and of the many; which was moulded into the laws, the manners, and civil institutions of nations, and blended with the frame and policy of states; could not be brought to the ground without a fearful struggle; nor could it fall without a violent *concussion* of itself and all about it.

Burke.

Winds from all quarters agitate the air,
And fit the limpid element for use,

Else noxious; oceans, rivers, lakes, and streams,
All feel the freshening impulse, and are cleansed
By restless undulation; e'en the oak

Thrives by the rude *concussion* of the storm.

Cowper.

Palsy's cold hands the fierce *concussion* own,
And life clings trembling on her tottering throne.

Parwin.

COND, *v. a.* } Goth. *kunde*. To guide or

CON'DER, *n. s.* } conduct a ship; to give notice. Con'd seems to be a maritime corruption of the verb to com, or con. A conder is a person who stands before the compass, and gives direction to the helmsman how to steer; it is also the name of a man employed in the manner described in the following quotation. Some etymologists, and not unplausibly, derive conder from the French, *conduire*. 'Such as stand upon high places near the sea coast, at the time of herring fishing, to make signs to the fisher which way the shoal passeth, which may better appear to such as stand upon some high cliff, by a kind of blue color that the fish causeth in the water, than to those in the ships. These he likewise called huers, by likelihood of the French, *huyer*, *exclamare*, and balkers.'

Cowell.

CONDAMINE (Charles Marie de la), a celebrated traveller and natural philosopher, was born in 1701, at Paris. His father, who was receiver-general of the taxes for the province of Bourbonnois, first procured him a situation in the army, but his desire of knowledge soon induced him to travel. In the year 1731, having resigned the military profession, he left his native country to visit the shores of the Mediterranean. He surveyed many parts of the coast of Africa and Asia, resided some time at Constantinople, and returned to Paris after nearly two years absence, where he published an account of his travels. This account was first read to the Academy of Sciences, as a member of which he had been admitted before his departure. By the same body he was appointed as one of their commissioner in the splendid undertaking of measuring a degree of the meridian and of the equator in Peru; and on the sixteenth of May, 1735, he and his philosophic companions set sail from Rochelle for this destination. This undertaking was at first suggested by Condamine, and its difficulties and dangers suited his zeal and enterprising spirit. It is well known what success attended the labors of the academicians both in Lapland and Peru; and nothing but the share that Condamine had in bringing them to a happy termination could give them any place in this narrative. After the instructions of the academy were fulfilled, one of the greatest of Condamine's adventures commenced. Having been

stimulated, by his curiosity and spirit of enterprise, to attempt a passage across the American continent, along the river Amazons, he committed himself to the stream of that river with a single servant, and after encountering various dangers, and surmounting numerous obstacles, he arrived at Cayenne, where he was obliged to wait more than five months for a vessel to carry him to Europe. This delay, amid the anxious desires that he must have felt to communicate the result of his labors and observations to his countrymen, and to enjoy in return their surprise and their admiration, produced a depression of spirits that sensibly affected his health. He recovered, however, when the opportunity at last occurred of his returning to Europe; and, in a vessel provided for him by the governor of Surinam, he was conveyed to Holland, and from thence hastened to Paris, where he was received with such universal applause as to excite the jealousy of his colleague, Bouquier, a man of more science and knowledge, but of retired and unassuming habits and manners. In 1757, several years after his return from South America, he undertook a journey to Italy for the benefit of his health; and, during his stay at Rome, procured from the church a dispensation to marry his niece. He afterwards published an account of several interesting observations he had made during this tour, in a book, entitled, *Extract d'un Journal de Voyage en Italie*. Inoculation for the small pox had been introduced about this time from Turkey into England; and in a visit which our traveller made to this country, he had observed the beneficial effects of the practice; on his return, therefore, he published in two volumes *Lettres et Memoires sur l' Inoculation*, stating what had been done, and what might be expected from doing more. While he was in London he was admitted a member of the Royal Society, an honor to which he had been elected several years before. He was also elected a member of many other learned societies, as those of Petersburg, Berlin, and Bologna. He died in 1774 in consequence of an operation for hernia. His peculiar propensities and habitual character may be collected from the foregoing brief account of his life. His reputation as a philosopher does not rank very high, although he had amassed extensive information, and was by no means destitute of science. Posterity will regard him rather as a man of brilliant parts and general knowledge, who, by his ardent and unremitting exertions, contributed to diffuse the light of science, than one who could add to its splendor, or bring new regions within its sphere.

CONDAPILLY, one of the northern Circars of Hindostan extending between the sixteenth and seventeenth degrees of north latitude, and sometimes called Mustapha Nagur; the entire district, occupies an area of 3400 miles, exclusive of the mountains on the west. It is on the whole well cultivated; but the diamond mines have long ceased to be productive. It is well watered by the Krishna and some minor streams. The principal towns are Condapilly, Masulipatam, and Tron-tailoor.

CONDAPILLY, the capital of the above province, is situated on a hill and was formerly esteemed

a place of much strength; but the fortifications have of late been neglected. The principal officers of the government reside at Masulipatam. Condapilly, according to Mr. Hamilton, was first conquered from the Hindoo princes, about the year 1471, by the Bhamenee sovereigns of the Deccan, and it came into the British possession, along with the northern Circars, in 1765. Travelling distance from Hyderabad, 142 miles; from Madras 306; and from Seringapatam 444 miles.

CONDATCHY, a bay and town of the island of Ceylon, where is carried on a very extensive pearl fishery. The banks on which the oysters are found, extend about forty miles along this coast. See our article CEYLON. In the town reside the polishers and drillers of the pearls. The neighbourhood is distinguished for nothing else.

CONDE, a strong town of France, in the department of the North. It first came into the possession of France at the peace of Nimeguen, in 1679, when the works were strengthened. It was one of the French fortresses occupied by the allies of the second treaty of Paris, in 1815, and is now regarded as one of the strongest barrier-fortresses on this side the Netherlands. It was taken by the allies, July 10th, 1793, but retaken in October, 1794, and its name changed for a time, by a decree of the convention, to Nord Libre, or North Free. It is seated at the confluence of the Scheld and the Haisne, twelve miles south-east of Tournay, containing about 6000 inhabitants; thirteen miles west of Mons, seven N. N. E. of Valenciennes; and 117 north by east of Paris.

CONDE (Lewis de Bourbon, prince of), one of the greatest generals of his age, was born at Paris, September 7th, 1621. He was styled Duke d' Enghien, till by his father's death, in 1646, he succeeded to the title of prince of Conde. Three years previous to this event, at the age of twenty-two, the king, by the advice of cardinal Mazarine, gave him the command of the army destined to cover Champagne and Picardy; and in this station he soon established his reputation, by defeating the Spaniards at Rocroi, and by the siege and capture of Thionville. Having covered Alsace and Lorraine from the enterprises of the imperialists, he returned to Paris, and obtained the government of Champagne, and of the city of Stenai. In 1644, 1645, and 1646, he distinguished himself in the three battles of Frisbourg, and by the taking of Philipsbourgh making himself master of the palatinate, and of the whole course of the Rhine, by the siege and conquest of Dunkirk, and by the siege of Lerida, from which, though he was obliged to rise, he kept the Spaniards in awe, and cut to pieces their rear-guard. During the civil wars, arising out of the administration of cardinal Mazarine, and the conduct of the queen-mother, he joined the malcontents, for which conduct he was arrested and detained a year in prison. In the civil war which ensued, he was opposed by Turenne, and would probably have been defeated, but for the assistance of mademoiselle, the daughter of the duke of Orleans, who caused the cannon of the bastille to be fired at the king's troops. On the restoration of peace he

went into the Low Countries, where he joined the Spaniards. In 1659, on the peace of the Pyrenees, the prince was re-established in France, and afterwards employed in Flanders against the prince of Orange. He was wounded at the passage of the Rhine, but he continued the war, notwithstanding, with activity, and reduced the whole of Franche-Comté. Succeeding Turenne in the command of the French army, he was sent in 1675 into Alsace to check the progress of the imperial general Montecuculi. He obliged the enemy to cross the Rhine, and then closed his military career. He now retired to Chantilly to combat with the gout, and passed the rest of his life in cultivating the fine arts, in which he had considerable taste. He died in 1686, at Fontainebleau, leaving two sons.

CONDEMN, *v. a.* } Fr. *condemner*; Ital. }
 CONDEMNABLE, *adj.* } *condannare, conden-*
 CONDEMNATION, *n. s.* } *nare*; Sp. *condenar*; }
 CONDEMNATORY, *adj.* } Lat. *condemnatio*. Tooke }
 CONDEMNEDLY, *adv.* } considers the Ang- }
 CONDEMNER, *n. s.* } Sax. *deman*, to deem, }
 CONDEMNING, *n. s.* } as being the root of the }
 English word. To condemn is to pronounce criminal; to pass sentence; to censure; to reprehend; to inflict a fine; to show guilt by contrast.

The righteous that is dead shall *condemn* the ungodly which are living. *Wisdom iv. 16.*

And the king of Egypt put him down at Jerusalem, and *condemned* the land in an hundred talents of silver. *2 Chronicles xxxvi. 3.*

The son of man shall be betrayed unto the scribes, and they shall *condemn* him to death. *Matt. xx. 13.*
 There is therefore now no *condemnation* to them.

Rom. viii. 1.

Who is he that *condemne*th? It is Christ that died, yea, rather that is risen again. *Rom. viii. 34.*

But O vaine judgment, and conditions vaine,
 That which the prisoner points unto the free;

The whites I him *condemne*, and deeme his paine,

He where he lists goes loose, and laughs at me.

Spenser's Faerie Queene.

Condemned to that dungeon merciless,
 Where they should live in wo, and dye in wretchednesse *ll.*

One while she blamed herselfe, another while
 She him *condemned* as trustlesse and untrew. *ll.*

My conscience hath a thousand several tongues,

And every tongue brings in a several tale,

And every tale *condemns* me for a villain.

Shakespeare. Richard III.

Is he found guilty? ———

——— Yes, truly, is he, and *condemned* upon't.

ll. Henry VIII.

And if we dare to judge our Maker's will,
 He can *condemn* us, and himself can clear. *Davies.*

He commands to deface the print of a candle in ashes; which strictly to observe, were *condemnable* superstition. *Browne.*

Since thou determinest weakness for no plea,

In man or woman, thought to thy own *condemning*,

Hear what assaults I had. *Milton. Samson Agonistes.*

The poet, who flourished in the scene, is *condemned* in the ruelle. *Dryden's Æneid, Preface.*

He who was so unjust as to do his brother an injury, will scarce be so just as to *condemn* himself for it.

Locke.

He that passes the first *condemnatory* sentence, is like the incendiary in a popular tumult, who is chargeable with all those disorders to which he gave rise.

Government of the Tongue.

Some few are the only refusers and *condemners* of this catholic practice. *Taylor's Worthy Communicant.*

They who approve my conduct in this particular, are much more numerous than those who *condemn* it.

Spectator.

Considered as a judge, it *condemns* where it ought to absolve, and pronounces absolution where it ought to *condemn*.

Fiddes's Sermons.

Escaped the dungeon, does the slave complain,
 Nor bless the friendly hand that broke the chain?

Say, pines not Virtue for the lingering morn,

On this dark wild *condemned* to roam forlorn! *Beattie.*

The laws in many countries to *condemn* require more than a mere majority; less than an equal number to acquit. In our judicial tribunals we require unanimity either to *condemn* or absolve. *Burke.*

When the trial is by friends, if the decision should happen to be favourable, the honour of the acquittal is lessened; if adverse, the *condemnation* is exceedingly embittered. It is aggravated by coming from lips professing friendship, and pronouncing judgment with sorrow and reluctance. *Id.*

Condemns the injurious deed, the slanderous tongue,
 The thought that meditates a brother's wrong;

Brings not alone the more conspicuous part,

His conduct, to the test, but tries his heart. *Cowper.*

Your sneaking water drinkers all

I utterly *condemn* 'em,

He that would write like Homer,

Must drink like Agamemnon. *Huddesford.*

CONDENSE, *v. a. & n. & adj.* } Fr. *conden-*

CONDENSATE, *v. a. & n. & adj.* } *sar*; Ital. *con-*

CONDENSATION, *n.* } *densare*; Span. }

CONDENSABLE, *adj.* } *condensar*; Lat. }

CONDENSATIVE, *adj.* } *condensar*. — }

CONDENSER, *n. s.* } The verbs *con-*

CONDENSITY, *n. s.* } *densare* and *con-*

densate are synonymous. Both mean to thicken; to compress into a narrower space; to be thickened; to be compressed into a narrower space. The kindred words do not require definition; with the exception of the scientific term *condenser*, which denotes an apparatus for compressing the air into a strong metallic vessel. See the next article.

If by natural arguments it may be proved, that water, by *condensation*, may become earth; the same reason teacheth that earth, rarefied, may become water. *Raleigh's History.*

By water-glasses the account was not regular; for, from attenuation and *condensation*, the hours were shorter in hot weather than in cold.

Brown's Vulgar Errors.

Moving in so high a sphere, he must needs, as the sun, raise many obvious exhalations; which, *condensed* by a popular odium, were capable to cloud the brightest merit. *King Charles.*

This agent meets with resistance in the moveable; and not being in the utmost extremity of density, but *condensable* yet further, every resistance works something upon the mover to condense it.

Digby on the Soul.

Water by nature is white; yea, thickened or *condensate*, most white, as it appeareth by the hail and snow. *Pearchain.*

They colour, shape, and size

Assume, as likes them best, *condense* or rare

Milton.

The water falling from the upper parts of the cave, does presently there *condense* into little stones.

Boyle's Scept. Chym.

Some lead their youth abroad, while some *condense*
Their liquid store, and some in cells dispense.

Dryden's Virgil.

All vapours, when they begin to *condense* and
coalesce into small parcels, become first of that bigness
whereby azure must be reflected, before they can con-
stitute other colours.

Newton's Opticks.

Such dense and solid strata arrest the vapour at the
surface of the earth, and collect and *condense* it there.

Woodward.

The supply of its moisture is by rains and snow,
and dews and *condensation* of vapours, and perhaps by
subterraneous passages.

Bentley.

They might be separated without associating into
the huge *condense* bodies of planets.

Id. Sermons.

For them the rocks dissolved into a flood,

The dews *condensed* into angelic food,

Their very garments sacred, old yet new,

And Time forbid to touch them as he flew.

Couper.

O'er those blest isles no ice-crowned mountains
towered,

No lightnings darted, and no tempests loured;

Soft fell the vesper drops *condensed* below,

Or bent in air the rain-refracted bow.

Darwin.

When heaven's high vault *condensing* clouds de-
form,

Fair Amaryllis flies the incumbent storm,

Seeks with unsteady step the sheltered vale,

And turns her blushing beauties from the gale.

Id.

It is also well known, that the thinner the glass is,
(which is thus coated on both sides so as to make a
Leyden phial), the more electricity can be *condensed*
on one of its surfaces, till it becomes so thin as to
break, and thence discharge itself. Nor is it possible
that the quantity of electricity *condensable* on one side
of a coated phial, may increase in some high ratio in
respect to the thinness of the glass.

Id.

CONDENSATION, is commonly applied to the
conversion of vapor into water, by distillation,
or naturally in the clouds. Vapor com-
monly condenses by the application of some
cold substance. On touching it the vapor parts
with its heat which it had before absorbed, im-
mediately loses the proper characteristics of
vapor, and becomes water. But though this is
the most common and usual way in which we
observe vapor to be condensed, nature certainly
proceeds after another method: since we often
observe the vapors most plentifully condensed
when the weather is really warmer than at other
times. See CLOUDS.

A CONDENSER is a pneumatic engine by which
an uncommon quantity of air may be forced into
a small space; so that sometimes ten atmos-
pheres, or ten times as much air as there is at
the same time in the same space, without the
engine, may be thrown in by means of it, and
its egress prevented by valves properly disposed.
It consists of a brass cylinder, wherein is a move-
able piston, which being drawn out, the air
rushes into the cylinder through a hole provided
on purpose; and, when the piston is again forced
into the cylinder, the air is driven into the re-
ceiver through an orifice, furnished with a valve
to hinder its getting out. The receiver, or vessel
containing the condensed air, should be made
very strong, to bear the force of the air's spring
thus increased; for which reason they are gene-
rally made of brass: its orifice is fitted with a
female screw to receive the male screw at the

end of the condenser. Some condensers are
made of glass for entertaining experiments, but
they cannot bear much condensation.

CONDESCEND, <i>v. n.</i>	} Fr. <i>condescen-</i> <i>dre</i> ; It. <i>condescen-</i> <i>dere</i> ; Span. <i>con-</i> <i>descender</i> ; Latin <i>condescendere</i> . The primary idea of all these words is voluntarily abating of, or yielding up,
CONDESCENCE, <i>n. s.</i>	
CONDESCENDENCE, <i>n. s.</i>	
CONDESCENDENCY, <i>n. s.</i>	
CONDESCENDING, <i>n. s.</i>	
CONDESCENDINGLY, <i>adv.</i>	
CONDESCENSION, <i>n. s.</i>	

CONDESCENSIVE, *adj.*
CONDESCENT, *n. s.*

something that is due; gracefully descending
from superiority; putting ourselves partly on a
level with those who have no claim to be con-
sidered as our equals. Condесent, condес-
cendence, and condесcence, are old synonymes
with condесcension.

Alas, my lord! take from me this damage;

To my desire for mercy *condescende*,

For none but thou may my grievance amende.

Chaucer.

They, rather to gratify Heriodias, made way for so
slight and easy a *condесcent*.

Hall.

By the warrant of St. Paul's *condесcendence* to the
capacities he wrote unto, I may speak after the man-
ner of men.

Montague

This queen of most familiar *condесcendings* is con-
tent to be our every week's prospect.

Hammond.

Can they think me so broken, so debased,
With corporal servitude that my mind ever
Will *condесcend* to such absurd commands.

Milton.

Nor shall my resolution

Disarm itself, nor *condесcend* to parly

With foolish hopes.

Denham's Sophy.

Spain's mighty monarch,

In gracious clemency does *condесcend*,

On these conditions, to become your friend.

Dryden's Indian Emperor.

He did not primarily intend to appoint this way;
but *condесcended* to it, as accommodate to their pre-
sent state.

Tillotson.

It forbids pride, and ambition, and vain glory; and
commands humility, and modesty, and *condесcension*
to others.

Id.

Raphael, amidst his tenderness, shews such a dig-
nity and *condесcension* in all his behaviour, as are
suitable to a superior nature.

Addison.

We *condесcendingly* made Luther's works umpires
in the controversy.

Atterbury.

Courtesy and *condесcension* is a happy quality,
which never fails to make its way into the good opi-
nion, and into the very heart; and allays the envy
which always attends a high station.

Id. Sermons.

This method carries a very humble and *condесcend-*
ing air, when he that instructs seems to be the en-
quirer.

Watts

There is, indeed, this difference from the Saxon
times, that as in the itinerant exhibitions of the stage,
for want of a complete company, they are obliged to
throw a variety of parts on one performer, so our so-
vereign *condесcends* himself to act, not only the prin-
cipal, but all the subordinate parts of the play. He
condесcends to dissipate the royal character, and to
trifle with those light subordinate lacquered sceptres,
in those hands that sustain the ball, representing the
world, or which wield the trident that commands the
ocean.

Burke.

If guards, mechanically formed in ranks,
Playing at beat of drum their martial pranks,

Shouldering and standing as if stuck to stone,
While *condescending* majesty looks on;
If monarchy consist in such base things,
Sighing, I say again, I pity kings!

Cowper.

If ever I should *condescend* to prose,

I'll write poetical commandments, which

Shall supersede beyond all doubt all those

That went before; in these I shall enrich

My text with many things that no one knows,

And carry precept to the highest pitch.

Byron's Don Juan.

CONDIGN, *adj.* } Fr. *condigne*; Ital. *con-*

CONDIGNNESS, *n. s.* } *degno*; Span. *condigno*;

CONDIGNITY, *n. s.* } *lat. condignus*. Worthy;

CONDIGNLY, *adv.* } merited. When used in

conjunction with the noun punishment, to which it is almost confined, it implies a degree of severity. Johnson says that it is always applied to something deserved by crimes. This assertion Mr. Todd controverts, and refers to our old writers for proofs of the contrary. Johnson, however, is in the right, as far as regards the present time; the adjective being now never used but in the manner which he specifies. *Condignity* is equivalent to merit; desert.

Herself of all that rule she deemed most *condigne*.

Spenser's Faerie Queene.

Unless it were a bloody murderer,

I never gave them *condigna* punishment.

Shakspeare. Henry VI.

Such a worthiness of *condignity*, and proper merit of the heavenly glory, cannot be found in any of the best, most perfect, and excellent of created beings.

Bishop Bull.

As Mercury has turned himself into me, so I may take the toy into my head to turn myself into Mercury, that I may swinge you off *condignly*.

Dryden's Amphitryon.

Consider who is your friend, he that would have brought him to *condign* punishment, or he that has saved him.

Arbuthnot.

CONDILLAC (Stephen Bonnet de), was an eminent French metaphysician, who attained great distinction by his writings on the most abstruse subjects. The work by which he first became known to the public, and which will probably constitute his best passport to fame among posterity, was a metaphysical treatise which he published in 1746, entitled an *Essay on the Origin of Human Knowledge*. Six years afterwards he published a *Treatise on Sensation*, which is regarded as more ingenious and more original, if possible, than his first work. In the following year he published a *Treatise on the Nature of Animals*. His object is to show that the actions they perform, and the faculties they manifest, cannot be explained on the principles of Descartes, of their being merely machines of more delicate construction. His most extensive work is entitled, *A Course of Study*, drawn up for the instruction of the Prince of Parma. This was published in the year 1776, and consists of sixteen volumes. His last work was entitled, *Commerce and Government* considered relatively to each other. He died in 1780, a short time after the publication of the treatise above mentioned, and left behind him a reputation for talents of the first order, extensive general knowledge, and great metaphysical penetration.

CONDIMENT, *n. s.* Ital. *condimento*; Lat. *condimentum*. Seasoning; sauce; that which excites the appetite by a pungent taste.

As for radish and the like, they are for *condiments* and not for nourishment. *Bacon's Natural History.*

Many things are swallowed by animals rather for *condiment*, gust, or mendicament, than any substantial nutriment. *Brouene.*

CONDISCIPLE, *n. s.* Lat. *condiscipulus*. A schoolfellow; a fellow disciple.

A *condisciple* of his, or one that had been, hearing so much of the man, went to him. *M. Casaubon.*

CONDISE, *n. s.* A conduit. The word is used by Chaucer, and the spelling was probably altered by him to make it chime with the ending of the preceding line.

CONDITE, *v. a. & adj.* } Ital. and Lat. *con-*
CONDITEMENT, *n. s.* } *ditum*. To pickle; to
CONDITING, *n. s.* } preserve by salt,
sugar, or aromatics; to season. *Conditement* signifies a composition of preserves, powders, and spice, blended together, by means of syrup, into an electuary.

The most innocent of them are but like *condited* or pickled mushrooms, which, carefully corrected, may be harmless, but can never do good.

Taylor's Rule of Holy Living.

Scoltzj would fain have them use all summer the *condite* flowers of succory, strawberry water, &c.

Barton. Anatomy of Melancholy.

Much after the same manner as the sugar doth, in the *conditing* of pears, quinces, and the like.

Grew's Museum.

CONDITION, *v. a. v. n. & n. s.* } Fr. *con-*
CONDITIONAL, *n. s. & adj.* } *dition*; It.
CONDITIONALITY, *n. s.* } *condizione*;
CONDITIONALLY, *adv.* } Sp. *condi-*
CONDITIONARY, *adj.* } *cion*; Lat.
CONDITIONATE, *v. a. & adj.* } *conditus*.
CONDITIONED, *adj.* } The lead-
CONDITIONLY, *adv.* } ing idea of

condition is, the state, make, or disposition, of any thing. The applications are numerous. The noun denotes quality, whether good or bad, moral or physical; distinctive property or attribute; external circumstances; rank; terms of agreement; the writing in which those terms are contained. The verb signifies to stipulate; to enter into terms. Conditional and conditionally mean that the act is done under some condition, the non-performance of which voids the contract. Sidney has conditionly in the sense of the latter word. A condition is that which limits or restricts what otherwise would be unconfined in its operation. To conditionate is to qualify; to regulate. Conditioned is the having properties, whether good or bad. Johnson denominates conditional an adjective, and defines it, stipulated; but, in the sentence which he quotes, unless we suppose a harsh ellipsis, the word is equivalent to condition, and, consequently, is a noun.

For trelliche I holde it a grete deinite,

A kinge's son in armis wel to do,

And be of gode *condicions* therto,

For grete power and moral vertue here

Is s-ldre isene in one person ifere.

Chaucer. Troilus and Criseide.

But half so well beloved a man as he,
 Ne was ther never in court of his degre.
 He was so gentil of *condition*,
 That thurghout all the court was his renoun.

Id. Canterbury Tales.

Bl'phely, (and he) come, sit the down;
 I te) the on *conditoun*,
 Thou shalt wholly with all thy wit
 Dy thyne entente to herlion it. *Id.*

Hardie thing it is to weene by might
 That man to hard *conditions* to bind,
 Or ever hope to match in equal fight,
 Whose prowessse paragone saw never living wight.
Spenser. Faerie Queene.

Every substance is *conditioned*
 To change her hew, and sendry forms to don,
 Meet for her temper and complexion. *Id.*

The child taketh most of his nature of the mother,
 besides speech, manners and inclination, which are
 agreeable to the *conditions* of their mothers.

Id. on Ireland.

For the use we have his express commandment,
 for the effect his *conditional* promise; so that, without
 obedience to the one, there is of the other no as-
 surance. *Hooker.*

A rage, whose heat hath this *condition*,
 That nothing can allay, nothing but blood.
Shakspeare. King John.

To us all,
 That feel the bruises of the days before,
 And suffer the *condition* of these times
 To lay an heavy and unequal hand
 Upon our noums. *Shakspeare. Henry IV.*

I am, in my *condition*,
 A prince, Miranda. *Id. Tempest.*

I here entail
 The crown to thee, and to thine heirs for ever;
Conditionally, that ere thou take an oath
 To cease his civil war. *Id. Henry VI.*

The dearest friend to me, the kindest man,
 The best *conditioned*. *Merchant of Venice.*

I yield upon *conditions*.—We give none
 To traitors: strike him down.
Ben Jonson's Cataline.

Jupiter is hot and moist, temperate, modest, honest,
 adventurous, liberal, merciful, loving, and faithful;
 that is, giving these inclinations: and therefore those
 ancient kings, beautified with these *conditions*, might
 be called thereafter Jupiter.

Raleigh's History of the World.

It was *conditioned* between Saturn and Titan, that
 Saturn should put to death all his male children. *Id.*

It seemed to us a *condition* and property of Divine
 Powers and Beings, to be hidden and unseen to
 others. *Bacon.*

He said, if he were sure that young man were king
 Edward's son, he would never bear arms against him.
 This case seems hard, both in respect of the *condi-*
tional, and in respect of the other words. *Id. Henry VII.*

Many are apt to believe remission of sins, but they
 believe it without the *condition* of repentance. *Taylor.*

Small towns, which stand stiff till great shot
 Enforce them, by war's law *condition* not. *Donne.*
 That ivy ariseth but where it may be supported, we
 cannot ascribe the same unto any science therein,
 which suspends and *conditionates* its eruption.

Broune's Vulgar Errors.

A false apprehension understands that positively,
 which was but *conditionally* expressed. *Id.*

The king himself met with many entertainments,
 at the charge of particular men, which had been
 rarely practised till then by the persons of the best
condition. *Clarendon.*

That which is mistaken to be particular and abso-
 lute, duly understood, is general, but *conditionate*;
 and belongs to none who shall not perform the *con-*
dition. *Hammond.*

Estimate the greatness of this mercy by the *con-*
dition it finds the sinner in, when God vouchsafes it
 to them. *South's Sermons.*

Many scriptures, though as to their formal terms
 they are absolute, yet as to their sense they are *con-*
ditional. *Id.*

We see large preferments tendered to him, but
conditionally, upon his doing wicked offices: con-
 science shall here, according to its office, interpose
 and protest. *Id.*

'Tis one thing, I must confess, to *condition* for a
 good office, and another thing to do it gratis.

L' Etrange.

Though uselessness, which is one of the *conditions*
 that makes punishments just, when it is away, may
 hinder punishments from being lawful in any body's
 hands; yet uselessness, when present, being but one
 of those *conditions*, cannot give the other, which is a
 commission to punish; without which also punish-
 ment is unlawful. *Locke.*

Not to be endured (a lie) in any one, who would
 converse with people of *condition*, or have any esteem
 or reputation in the world. *Id.*

And as this clear proposal of the promises may
 inspirit our endeavours, so is the *conditionality* most
 efficacious to necessitate and engage them.

Decay of Piety.

Would God in mercy dispense with it as a *condi-*
tionary, yet we could not be happy without it, as a
 natural qualification for heaven. *Norris.*

Did we perfectly know the state of our own *con-*
dition, and what was most proper for us, we might
 have reason to conclude our prayers not heard, if not
 answered. *Wake's Preparation.*

They will be able to conserve their properties un-
 changed in passing through severa' mediums; which
 is another *condition* of the rays of light.

Newton's Opticks.

Condition, circumstance, is not the thing;
 Bliss is the same in subject as in king.

Pope's Essay on Man.

Some desponding people take the kingdom to be in
 no *condition* of encouraging so numerous a breed of
 beggars. *Swift.*

The great inconvenience of public education arises
 from its being dangerous to morals; and, indeed,
 every *condition* and period of human life is liable to
 temptation. *Beattie.*

In considering any complex matter, we ought to
 examine every distinct ingredient in the composition,
 one by one; and reduce every thing to the utmost
 simplicity, since the *condition* of our nature binds us
 to strict law and very narrow limits. *Burke.*

CONDITION, in the civil law, a clause of obli-
 gation, stipulated as an article of a treaty, or a
 contract; or in a donation of a testament, legacy,
 &c. in which last case a donee does not lose his
 donative if it be charged with any dishonor or
 impossible conditions.

CONDITIONAL CONJUNCTIONS, in grammar,
 are those which serve to make propositions condi-
 tional: as *if, unless, provided, &c.*

CONDITIONAL PROPOSITIONS, in logic, such as
 consist of two parts connected together by a condi-
 tional particle.

CONDITIONAL SYLLOGISM, a syllogism where
 the major is a conditional proposition. Thus,
 'If there is a God, he ought to be worshipped.—

But there is a God;—therefore he ought to be worshipped.'

CONDO'LE, *v. n.* } Fr. *se condouloir*; It.
CONDO'LEMENT, *n. s.* } *condolersi*; Sp. *condolense*; Lat. *condolere*,
CONDO'LENCE, *n. s.* } from *con* and *dolere*.
CONDO'LING, *n. s.* } To sympathise with;
CONDO'LER, *n. s.* }

to express concern for the misfortunes or sorrows of others; to offer consolation; to lament or bewail with another. It has *with* before the person who is the object of our pity. Condolence is the opposite of congratulation.

Amongst the which there was a nymph that hight Molana, daughter of old father Mole,
And sister unto Mulla, faire and bright,
Unto whose bed false Bregog whylome stole,
That shepheard Colin dearely did *condole*.

Spenser. Faerie Queene.

To persevere

In obstinate *condolement*, is a course
Of impious stubbornness, unmanly grief.

Shakspeare. Hamlet.

come not, Sampson, to *condole* thy chance,

As these perhaps; yet wish it had not been,
Though for no friendly intent. *Milton's Agonistes.*

Why should I think that all that devout multitude,
which so lately cried Hosanna in the streets, did not
also bear their part in these public *condolings*?

Bishop Hall.

Why should our poet petition Isis for her safe delivery,
and afterwards *condole* her miscarriage?

Dryden.

Your friends would have cause to rejoice, rather
than *condole* with you. *Temple.*

I congratulate with the beasts upon this honour
done to their king; and must *condole* with us poor
mortals, as they are rendered incapable of paying our
respects. *Addison.*

The reader will excuse this digression, due by way
of *condolence* to my worthy brethren. *Arbutnot.*

We are still in the old cut; and have not so far
conformed to the new Parisian mode of good-breed-
ing, as to think it quite in the most refined strain of
delicate compliment (whether in *condolence* or congratulation)
to say to the most humiliated creature that
crawls upon the earth, that great public benefits are
derived from the murder of his servants, the attempted
assassination of himself and his wife, and the mortifi-
cation, disgrace, and degradation, that he has
personally suffered. *Burke.*

CONDOM, a town of France, in the depart-
ment of Gers, and ci-devant province of Gascony,
containing about 7000 inhabitants, who
manufacture wax and wool: the trade, princi-
pally with Bourdeaux, is in corn, wine, brandy,
leather and the above manufactures. Condom
was once a bishop's see, and filled by the cele-
brated Bossuet before he became bishop of
Meaux. The neighbourhood is very fertile and
delightful. It is seated on the Baize and the
Gelisse, twenty-eight miles south-east of Bour-
deaux.

CONDOMA, in zoology. See CAPRA.

CONDONATION. Lat. *condonatio*. A
forgiving of transgression. The word is now
obsolete, except in the ecclesiastical court, which
it is still in use, to express the forgiveness of a
wife by a husband after she has been unfaithful
to his bed.

CONDOR, in ornithology. See VULUR.

CONDORCET (John Antony Nicolas),
Caritat, marquis of, a celebrated French author,
philosopher, and politician. He was born at
Ribemont in Picardy, in 1743, and educated at
the college of Navarre, where he distinguished
himself by his attachment to the study of the
mathematics and physical science. On entering
into public life, he became intimate with Vol-
taire, D'Alembert, and the literati of their school.
As a mathematician Condorcet first attracted
public attention by a treatise on Integral Calcu-
lations, composed when he was twenty-two years
of age. His solution of the problem of the
Three Bodies appeared in 1767, and the first
part of his Essay on Analysis in 1768. He was
admitted a member of the Academy of Sciences
in 1769, and contributed greatly to enrich its
memoirs by various papers on the most abstruse
branches of mathematical science. Turgot soon
after this united him with D'Alembert and Bos-
suet, in constructing the various financial calcu-
lations of his administration. Meanwhile he
was indefatigable in the study of politics and
metaphysics, and published a defence of the
sect with which he was connected, from an at-
tack upon them in the *Trois Siecles*; as well as
a reply to M. Neckar's Essay on the Corn Laws.
In 1773 he was appointed secretary to the Aca-
demy of Sciences. In 1783 he pronounced an
oration before the Academy on the influence of
philosophy, and was received into that body.
D'Alembert dying this year, Condorcet suc-
ceeded to his place of secretary to the Academy,
and rendered himself conspicuous by the publi-
cation of eulogies on different eminent charac-
ters; particularly by that on his predecessor.
In his encomium on the famous Euler, he en-
tered into a circumstantial account of the specific
improvements in science and the mathematics
suggested by that individual; a species of me-
moir for which Condorcet had a peculiar taste.
In 1787 he published his labored *Life of Vol-
taire*. His last biographical sketch was an
eulogy on the celebrated Dr. Franklin, which
appeared in 1790.

We now come to a somewhat more active
part of the life of Condorcet. When the French
revolution took place, he was the chief conductor
of La Bibliotheque de l'Homme, designed to
analyse the writings of the most eminent politi-
cians; and of a newspaper entitled La Chro-
nique de Paris, full of declamation against
royalty; as well as an assistant in the Journal de
Paris. About the time the unfortunate Louis
XVI. fled to Varennes, he proposed a paper called
Le Republicain, and became an active member
of the Jacobin club. When the constituent na-
tional assembly was dissolved, he was chosen
representative for Paris, and adhered to the
Brissotine party. He was now employed in
drawing up a plan for public instruction, which
he completed in two elaborate memoirs. He
also drew up the manifesto addressed to the
European powers by the people of France, on
the approach of war, and became president of
the national assembly.

In this capacity he wrote a letter of expostu-
lation to the king, and is said to have vindicated
the populace in insulting that unfortunate prince

Amidst this degradation of royalty, it is also said, that he secretly solicited the office of tutor to the dauphin; but was decidedly rejected by the king, on account of his infidelity. When the trial of the king was agitated, Condorcet gave it as his opinion that he could not be brought to judgment in a legal manner; though his conduct in regard to the final sentence appears ambiguous. Madame Roland says 'the genius of Condorcet is equal to the comprehension of the greatest truths; but he has no other characteristic besides fear. It may be said of his understanding, combined with his person, that it is a fine essence absorbed in cotton.' After the death of the king, Condorcet was employed by the Girondists to frame a new constitution, which was approved by that party; though not by the people at large. Condorcet's native timidity prevented him from taking part with either the Gironde or mountain parties, during the struggle between them; and he escaped the general massacre of the Brissotines; but he fell under the invincible displeasure of the blood-thirsty Robespierre, and a decree of arrest was passed against him in July 1793. He concealed himself in Paris for about nine months; but a rumor of a domiciliary visit led him to quit his place of abode, and passing through the barriers without being noticed, he went to the house of a friend at Mont-Rouge, who unfortunately happened to be then in Paris, and was not to return for three days. He was thus obliged to pass two dreary nights in the open fields, and venturing to a small inn at Calmars, the keenness with which he devoured what he ordered and his meagre appearance, attracted the attention of an officer, through whom he was thrown into a dungeon, to be carried to Paris next day; but in the morning, 28th of March, 1794, was found dead; as it is supposed by poison, as he generally carried it about him. Thus terminated the life of Condorcet, after thirty years of study, consecrated to the sciences and his country, or rather to all Europe; and after laboring for years exclusively for the revolution and liberty. Not long after his death, appeared his Sketch of an Historical picture of the Progress of the Human Mind. He also left behind him in MS. a Treatise on Calculation, and an Elementary Treatise on Arithmetic; and published, besides the works already noticed, Letters to the King of Prussia, with whom, as well as with Catharine, empress of Russia, he kept up a correspondence. Although Condorcet was professedly hostile to revealed religion, he was, in a philosophical sense, a man of integrity and virtue.

CONDORÉ, or PULO CONDORÉ, an island in the Indian Ocean, near the coast of Cochin China. It has an excellent harbour; which induced the English East India Company to form a settlement here in 1702, but a quarrel happening, most of the factory were murdered by the Cochin Chinese, and the rest expelled in 1705. This and the neighbouring cluster of islands abound with mangoe trees. See MANGIFERA. The natives are of a dark olive color; short, but well shaped; their faces are long and their hair long and black; they have small black

eyes, high noses, thin lips, white teeth and little mouths. The women are said to be licentious in their manners. The island is about twelve miles long and two broad.

CONDORMIENTES, Lat. in church history, religious sectaries, so named from lying all together, men and women, young and old. They arose in the thirteenth century, near Cologne; where they are said to have worshipped an image of Lucifer, and to have received oracular answers from him.

CONDRIEU, or CONDRIEUX, a flourishing town of France, in the department of the Rhone and Loire, remarkable for its wines. It is seated at the foot of a hill seventeen miles south of Lyons, and contains 4050 inhabitants.

CONDRUSII, in ancient geography, a people of Belgica, originally Germans, dwelling about the Maese, in the country, now Condroz.

CONDU'CE, <i>v. a. & v. n.</i>	} Lat. <i>conducere</i> . The verb followed by <i>to</i> , signifies to further some purpose; to contribute to bring about. By our old writers it was used in the sense of to conduct, but this is become obsolete. Conducement means tendency. Hale employs <i>conducibile</i> as a noun, 'the conducibles thereunto.' The adjective <i>conducibile</i> takes <i>to</i> after it.
CONDU'CEMENT, <i>n. s.</i>	
CONDU'CENT, <i>adj.</i>	
CONDUCTI'BLITY, <i>n. s.</i>	
CONDU'CIBLE, <i>n. s. & adj.</i>	
CONDU'CIBLY, <i>adv.</i>	
CONDU'CIBLENESS, <i>n. s.</i>	
CONDU'CI'VE, <i>adj.</i>	
CONDU'CI'VENS, <i>n. s.</i>	

The boring of holes in this kind of wood, and then laying it abroad, seemeth to *conduce* to make it shine.

Bacon.

The means and preparations that may *conduce* unto the enterprize.

Id. Holy War.

To both, the medium which is most propitious and *conducibile*, is air.

Id. Natural History.

He was sent to *conduce* hither the princess Henrietta Maria.

Wotton.

I give you free and full power to move the heads, or to do any other act fitting or *conducive* to the good success of this business.

Archbishop Laud.

Which two contemplations are not inferior to any for either pleasantness in themselves, or *conducibleness* for the finding out of the right frame of nature.

H. More.

Those motions of generations and corruptions, and of the *conducibles* thereunto, are wisely and admirably ordered and contemporated by the rector of all things.

Hale.

None of these magnetical experiments are sufficient for a perpetual motion, though those kind of qualities seem most *conducive* unto it.

Wilkin's Mathematical Magick.

I mention some examples of the *conduciveness* of the smallness of a body's parts to its fluidity.

Boyle.

An action, however *conducive* to the good of our country, will be represented as prejudicial to it.

Addison's Freeholder.

Every man does love or hate things, according as he apprehends them to *conduce* to this end, or to contradict it.

Tillotson.

They may *conduce* to farther discoveries for completing the theory of light.

Newton.

Our Saviour hath enjoined us a reasonable service; all his laws are in themselves *conducive* to the temporal interest of them that observe them.

Bentley.

CONDUCT, *v. a.* } Fr. *conduire*; Ital.
 CO'NDUCT, *n. s.* } *conduire*; Span. *condu-*
 CONDUCTING, *n. s.* } *cir*; Lat. *conducere.*
 CONDUCTIOS, *n. s.* } To lead; to direct; to
 CONDUCTIOUS, *ad.* } guide; to have the ma-
 CONDUCTOR, *n. s.* } nagement of; to com-
 CONDU'TRESS, *n. s.* } mand troops; to usher

in. Conduct signifies the management of an affair; course of action; regularity of behaviour; the act of escorting or guarding; a guide; and, with the addition of the adjective *safe*, a written order to ensure protection from being injured. Conductitious means hired. Conduction is an obsolete word for the act of training up. In addition to its obvious senses, conductor denotes a surgical instrument, and a body capable of transmitting the electric fluid. See ELECTRICITY and SURGERY.

I was ashamed to ask the king footmen and horsemen, and *conduct* for safeguard against our adversaries,
Esdras 1.

So having all things well about her dight,
 She on her way east forward to proceede,
 And they her forth *conducted*.

Pray receive them nobly, and *conduct* them
 into our presence. *Shakspeare. Henry VIII.*

Some three or four of you,
 Go, give him courteous *conduct* to this place. *Id.*
 His majesty,

Tendering my person's safety, hath appointed
 This *conduct* to convey me to the Tower.
Id. Richard III.

Who is *conductor* of his people?
 As 'tis said, the bastard son of Gloucester.
Id. King Lear.

Young men, in the *conduct* and manage of actions,
 embrace more than they can hold, stir more than they
 can quiet, and fly to the end without consideration of
 the means. *Bacon.*

I shall straight *conduct* you to a hill side, where I
 will point you out the right path.
Milton on Education.

Conduct of armies is a prince's art. *Waller.*
 O may thy power, propitious still to me,
Conduct my steps to find the fatal tree,
 In this deep forest. *Dryden's Æneid.*

How void of reason are our hopes and fears!
 What in the *conduct* of our life appears
 So well designed, so luckily begun,
 But when we have our wish, we wish undone?
Id. Juvenal.

Shame of change, and fear of future ill;
 And zeal, the blind *conductor* of the will. *Id.*
 Every man must, some time or other, be trusted
 to himself and his own *conduct*; and he that is a
 good, virtuous, and able man, must be made so within.
Locke.

If he did not entirely project the union and re-
 gency, none will deny him to have been the chief
conductor in both. *Addison.*

Though all regard for reputation is not quite laid
 aside, it is so low, that very few think virtue and *con-*
duct of absolute necessity for preserving it. *Swift.*

The persons were neither titularies nor perpetual
 curates, but entirely *conductions*, and removeable at
 pleasure. *Ayliffe.*

There are even a sort of splendid impositions so
 well contrived, that, at the very time the path of rec-
 titude is quitted for ever, men seem to be advancing
 into some higher and nobler road of public *conduct*.
Eur.c.

If an inquiry thus carefully *conducted* should fail at
 last of discovering the truth, it may answer an end
 perhaps as useful, in discovering to us the weakness of
 our own understanding. If it does not make us know-
 ing, it makes us modest. *Id.*

His fable is well *conducted*, and for the most part
 consistent with itself, and connected with probable
 circumstances. *Beattie.*

Instead of advising their king to consult his own
 and his peoples' dignity, by making the law the rule
 of his conduct, they have used him much more cruelly
 than our Charles I. was used; they have made him a
 prisoner and a slave. *Id.*

Thou withered sibly, my sage *conductress* (Frugal-
 ity), usher me into the refulgent, adored presence.
 The power (Wealth), splendid and potent as he now
 is, was once the puling nursing of thy faithful care
 and tender arms. *Bur*

Here Ouse, slow winding through a level plain
 Of spacious meads, with cattle sprinkled o'er,
Conducts the eye along his sinuous course
 Delighted. *Cowper.*

The air, like all other bad *conductors* of electricity,
 is known to be a bad *conductor* of heat. *Darwin.*
 CONDUCTORS, in electrical experiments, bodies
 that receive and communicate electricity.

CONDUCTIONS, in surgery, are used in laying up
 sinuses and fistulas.

CONDUIT, *n.* Fr. *conduit*. A water course:
 the pipe whence the water obtains egress. It is
 derived from *conduct*, the water being conducted
 to the spot where it is wanted. The figurative
 use of the word is obvious.

The Hode out of the wounde as brode as terte,
 As watir, whan the *conduite* broken is. *Chaucer.*

But all the liguour, which was foule and waste;
 Not good nor servicable elles for ought,
 They in another great rownd vessel plaste,
 Tell by a *conduit* pipe it thence was brought.

Spenser. Faerie Queene.
 This face of mine is hid
 In sap consuming winter's drizzled snow,
 And all the *conduits* of my blood froze up.

Shakspeare.
 I charge and command, that the *conduits* run
 nothing but claret wine. *Id. Henry VI.*

These *conduit* pipes of knowledge feed the mind;
 But the other three attend the body still. *Davies.*

These organs of the nerves, which are the *conduits*
 to convey them from without to their audience in the
 brain. *Locke.*

God is the fountain of honour; and the *conduits*,
 by which he conveys it to the sons of men, are virtu-
 ous and generous practices. *South.*

Wise nature likewise, they suppose,
 Has drawn two *conduits* down our nose. *Prior.*

CONDUITS are, in general, made of either
 lead or iron; those of stone being expensive
 and massy. The ancients, however, never used
 any other: the Romans excelled all other na-
 tions in the beauty of these works, above which
 a great part of their city stood. The cement of
 the stone works, beneath the water, soon became
 as hard as the stones which they joined, and the
 cloacinæ of Rome are yet among its most cele-
 brated antiquities. In Cheapside, London, there
 were once two celebrated conduits, the *Great* and
 the *Little*. The *Great* conduit was the first cis-
 tern of lead erected in the city: it was built in
 1285, and constructed principally of castellated
 stone. At the procession of Anne Boleyn it was
 repaired, and ran with white and claret wine all
 the afternoon.

CONDUPPLICATE, *v. a.* } Lat. *condupli-*
 CONDUPPLICATION, *n. s.* } *co, conduplicatio.*

To double, doubling.

CONDYLE, or the CONDYLOID PROCESS.
 See ANATOMY.

CONDYLOMA, in medicine, a tubercle, or callous eminence, which arises in the folds of the anus, or rather a swelling or hardening of the wrinkles of that part.

CONDYLUS, in anatomy, a knot in any of the joints, formed by the epiphysis of a bone.

CONE, *n. s.* } Fr. *cone*; Ital. and
 CONICK, *adj.* } Span. *cono*; Lat. *conus*;
 CO'NICAL, *adj.* } *κωνος*. A solid body,
 CO'NICALNESS, *n. s.* } the base of which is cir-
 CO'NICALLY, *adv.* } cular, and which gra-
 CONIFEROUS, *adj.* } dually diminishes in
 CONOID, *n. s.* } diameter, till it ends in
 CONOIDICAL, *adj.* } a point; also the fruit of
 the fir tree. Conoid signifies a figure which bears a resemblance to a cone. Coniferous is defined in the quotation from Quincy. The meaning of the kindred words is obvious. See CONIC SECTIONS.

Now had night measured with her shadowy *cone*
 Half way up hill this vast sublunar vault.

Paradise Lost.

The tympanum is not capable of tension as a drum; there remains another way, by drawing it to the centre into a *conoid* form.

Holder.

In a watering pot, shaped *conically*, or like a sugar-loaf, filled with water, no liquor falls through the holes at the bottom, whilst the gardener keeps his thumb upon the orifice at the top.

Boyle's Spring of the Air.

The *cones* dependent, long, and smooth, growing from the top of the branch.

Evelyn.

Tow'ring firs in *conic* forms arise,

And with a pointed spear divide the skies. *Prior.*

A brown flint of a *conic* figure: the basis is oblong.

Woodward.

They are *conical* vessels, with their bases towards the heart; and, as they pass on, their diameters grow still less.

Arbuthnot.

Such trees or herbs are *coniferous*, as bear a squamose scaly fruit, of a woody substance, and a figure approaching to a *cone*, in which are many seeds; and when they are ripe, the several cells in the *cone* open, and the seeds drop out. Of this kind are the fir, pine, and beech.

Quincy.

Burst from each pyramid expiring groans,
 And darker shadows stretched their lengthened *cones*.

Darwin.

In the West Indies the sea rises like a *cone* in the whirl, and is met by black clouds produced by the cold upper air and the warm lower air being rapidly mixed; whence are produced the great and sudden rains called water-spouts; while the upper and lower airs exchange their plus or minus electricity in perpetual lightnings.

Id.

But, as these are necessarily more or less of a cylindrical or *cone* form, the nodules or globular flints above described, cannot have been constructed in this manner.

Id.

CONE, in botany. See CONUS.

CONE, in geometry. See CONIC SECTIONS.

CONF, MELTING, in chemistry, is a hollow cone formed of copper or brass, with a handle, and with a flat bottom adjoining to the apex of the cone, upon which it is intended to rest. Its use is to receive a mass of one or more metals

melted together, and cast into it. This mass, when cold, may be easily shook out of the vessel, from its figure. Also, if a melted mass consisting of two or more metals, or other substances not combined together, be poured into this vessel, the conical figure facilitates the separation of these substances according to their respective densities. The cone ought to be well heated before the melted mass is thrown into it; that it may not contain any moisture, which would occasion a dangerous explosion. It ought also to be greased internally with tallow, to prevent the adhesion of the fluid matter.

CONE OF RAYS, in optics, includes all the several rays which fall from any radiant point upon the surface of a glass.

CONEY. See CONY.

CONFABULATE, *v. n.* } Old Fr. *confa-*
 CONFABULATION, *n. s.* } *buler*; Lat. *confa-*
 CONFABULATORY, *adj.* } *bulatio*. To talk familiarly together; to narrate tales; prattling; familiar talk; belonging to such talk.

I was going on in my *confabulation*, when Tranquillus entered. *Tatler.*

I shall not ask Jean Jacques Rousseau
 If birds *confabulate* or no;

'Tis clear that they were always able

To hold discourse at least in fable.

And even the child, who knows no better

Than to interpret by the letter

A story of a cock and bull,

Must have a most uncommon skull. *Cowper.*

CONFAMILIAR, *adj.* Compounded of con and familiar. Glanville uses it to signify that which has an intimate connexion with.

CONFARREATION, *n. s.* Lat. *confarreatio*. From *far*, corn. The solemnisation of marriage by eating bread together.

By the ancient laws of Romulus, the wife was by *confarreatio* joined to the husband. *Ayliffe's Par.*

CONFARREATION, among the ancient Romans, was used in the marriage of persons whose children were destined for the priest hood. It was the most sacred of their three modes of marrying. The pontifex maximus and flamen dialis joined and contracted the man and woman, by making them eat of the same cake of salted bread: whence the term *far*, signifying meal or flour. Ulpian says, it consisted in the offering up of some pure wheaten bread, and rehearsing a certain formula, in presence of ten witnesses. Dionysius Halicarnassus adds, that the husband and wife did eat of the same.

CONFATED, *adj.* From con and fate. The word is of rare occurrence. In Search's Freewill, &c., it is used to signify synonymously decreed; decreed at the same time with something else.

CONFECT, *v. a. & n. s.* } Fr. *confection*;
 CONFECTION, *n. s.* } Ital. *confezione*; Sp.
 CONFECTIIONED, *ad.* } *conficcio*; Lat. *con-*
 CONFECTIIONARY, *n. s.* } *ficere*. To confect
 CONFECTIIONER, *n. s.* } is, to make sweet-
 CONFECTORY, *adj.* } meats with sugar;

or to preserve by means of that substance. Confect, now corrupted into comfit, is a sweetmeat, generally solid, and in the shape of small spheres or eggs. Confection signifies, primarily, a sweetmeat, or fruit preserved with sugar; and, secondarily, an assemblage of various ingredients.

The confectioner, or confectionary, is the person whose trade it is to make sweetmeats, desert cakes, and other delicacies of a similar kind.

Spices belonging to the potiquanes,
 With many wholesome sweet confections. *Henderson.*
 Hast thou not learned me to preserve? yea so,
 That our great king himself doth woo me oft
 For my confections? *Shakspeare. Cymbeline.*
 Of best things then, what world shall yield con-
 fection
 To liken her? *Shakspeare.*
 Myself,

Who had the suck as my confectionary,
 The mouths, the tongues, the eyes, the hearts of men
 At duty, more than I could frame employments. *Id.*

There will be a new confection of mould, which
 perhaps will alter the seed. *Bacon.*

At supper eat a pipkin roasted, and sweetened
 with sugar of roses and carraway confects.
Harvey on Consumptions.

Nature's confectioner, the bee,
 Whose suckers are moist alchimy,
 The still of his refining mold
 Minting the garden into gold. *Cleveland.*

Confectioners make much use of whites of eggs.
Boyle.

He saw him devour fish and flesh, swallow wines
 and spices, confections, and fruits of numberless
 sweets and flavours. *Addison.*

Thy morning bounties ere I left my home.
 The biscuit, or confectionary plum;
 The fragrant waters on my cheeks bestowed
 By thy own hand, till fresh they shone and glowed;
 All this, and, more endearing still than all,
 Thy constant flow of love, that knew no fall.
Cowper.

CONFECTOR, among the ancient Romans, a
 sort of gladiator, hired to fight in the amphithe-
 atre against beasts; thus called à conficiendis
 bestiis, from their despatching and killing beasts.
 The Greeks called them ταραξολογ, q. d. daring,
 rash, desperate; whence the Latins borrowed
 the appellations parabolani and parabolarii. The
 Christians were sometimes condemned to this
 sort of combat.

CONFEDER, v. a.	} Fr. con- federer ;	
CONFÉDERATE, v. a., n., n. s., adj.		
CONFÉDERATING, n. s.		} Ital. con- federare ;
CONFEDERATION, n. s.		
CONFEDERACY, n. s.		} Sp. con- federar ;
CONFÉDERATOR, n. s.		

Lat *con* & *fiedus*. To confederate is, to league
 together; to combine for the purpose of mutu-
 ally supporting, or conjointly attacking. A
 confederation, or confederacy, is the league or
 alliance so formed; and a confederate, or con-
 federator, is one of the members of that alliance.
 To confeder is obsolete.

For they have consulted together with one consent:
 they are confederate against thee.

Psalm lxxxiii. 5.

Judas sent them to Rome, to make a league of amity
 and confederacy with them. *1 Macc. viii. 17.*

About her herse there stodin lustily
 Withoutin any mo as thoughtin me,
 Bountie, perfetly well armed and richely,
 And freshe Beaute, and Lust, and Jolite,
 Assurid Manir, Youthe, and Honeste,
 Wisdome, Estate, with Drede and Governauce,
 Confedrid both by honde and aliaunce. *Chaucer.*

VOL. VI.

All the swords

In Italy, and her confederate arms,
 Could not have made this peace.

Shakspeare. Coriolanus.

Sir Edmund Courtney, and the haughty prelate,
 With many more confederates, are in arms.

Id. Richard III.

What confederacy have you with the traitors?

Id. King Lear.

While the mind of man looketh upon second causes
 scattered, it may sometimes rest in them, and go no
 farther; but, when it beholdeth the chain of them
 confederate and linked together, it must need fly to
 providence and deity. *Bacon.*

The three princes enter into some strict league
 and confederation amongst themselves.

Bacon's Henry VII.

They were confederated with Charles's enemy.

Knolles.

With these the Piercys them confederate,
 And as three heads conjoin in one intent. *Daniel.*
 Nor can those confederations or designs be durable,
 when subjects make bankrupt of their allegiance.

King Charles.

By words men come to know one another's minds;
 by those they covenant and confederate. *South.*

This is a principle which is thought to extend itself
 to the dens of thieves, and the confederacies of the
 greatest villains. *Locke.*

Virgil has a whole confederacy against him, and I
 must endeavour to defend him. *Dryden.*

We still have fresh recruits in store,
 If our confederates can afford us more. *Id. Beach.*
 It is a confederating with him to whom the sacrifice
 is offered. *Athenry.*

In a confederate war, it ought to be considered
 which party has the deepest share in the quarrel.

Swift.

An avaricious man in office is in confederacy with
 the whole clan of his district, or dependance; which,
 in modern terms of art, is called to live and let live.

Id.

The friendships of the world are oft
 Confederacies in vice, or leagues of pleasure.

Addison.

Oh race confederate into crimes, that prove
 Triumphant o'er the eluded rage of Jove!

Pope's Statues.

But there is yet a liberty, unsung
 By poets, and by senators unprais'd,
 Which monarchs cannot grant, nor all the powers
 Of earth and hell confederate take away. *Cowper.*

Bad men, profaning friendship's hallow'd name,
 Form, in its stead, a covenant of shame:

A dark confederacy against the laws
 Of virtue, and religion's glorious cause. *Id.*

The minister, however, takes no strong ground of
 defence. I will not say he dare not take it. There
 he sits, to receive the attack of the new confederacy,
 who are not great in numbers, but in talents. The
 ex-minister is mounted on a kind of hill-fort, to fire
 down on the assailants, but the garrison is all manned
 with deserters from the principles of the war!

Sheridan.

CONFEDERACY, in law. See CONSPIRACY.

CONFEDERATION OF THE RHINE, the title
 by which several German states near the Rhine
 associated themselves into a body, at the com-
 mand, and under the protection, of the late
 emperor Napoleon Buonaparte. These states
 were formerly under the protection of the em-
 peror of Germany, and owed to him a certain
 degree of allegiance; but, after humbling the
 house of Austria in 1805, her haughty conqueror

Y

proceeded to diminish, or to annihilate, the influence of her authority, beyond the boundary of her own territories. He effectually dissolved the constitution of the German empire, forced Francis II. to abdicate what, in fact, had been for some time only a title of dignity, without any substantial power, and united under his own superintendance, and for his own aggrandisement, the most considerable states, which had formerly acknowledged a real or nominal subjection to the emperor. The league by which they were bound together was drawn up by the French government, and contained forty stipulations, possessing at this time but little interest. It was signed at Paris, August, 1806.

CONFÉR, *v. a. & n.* } Fr. *conférer*; It. *con-*
 CONFÉRENCE, *n. s.* } *ferire*; Sp. *conferrir*;
 CONFÉRRER, *n. s.* } Lat. *conferre*. To dis-
 CONFÉRRING, *n. s.* } course seriously, dis-
 cuss, or advise, together; to compare opinions and sentiments; to give; to bestow; and (but not of common use) to contribute or conduce to anything. Conference signifies conversing or discussing seriously; a formal meeting, convened for the purpose of discussing some important point; collation and comparison of things. Byron uses the verb in the sense of inflicted, which is, at least, unusual. When taken in the sense of to bestow, confer has on before the receiver of the gift; when it means to contribute it has to.

When they had commanded them to go aside out of the council, they *conferred* among themselves.

Acts iv. 15.

The *conference* of these two places, containing so excellent a piece of learning as this, expressed by so worthy a wit as Tully's was, must needs bring on pleasure to him that maketh true account of learning.

Ascham's Schoolmaster.

Sometime they deliver it, whom privately zeal and piety moveth to be instructors of others by *conference*; sometime of them it is taught, whom the church hath called to the public, either reading thereof, or interpreting.

Hooker.

You will hear us *confer* of this, and by an auricular assurance have your satisfaction.

Shakspeare. King Lear.

What passion hangs these weights upon my tongue! I cannot speak to her; yet she urged *conference*.

Shakspeare.

I shall grow skilful in country matters, if I have often *conference* with your servant.

Sidney.

Reading makes a full man, *conference* a ready man, and writing an exact man; and therefore, if a man write little, he had need have a great memory; if he *confer* little, he had need have a present wit; and, if he read little, he had need have much cunning, to seem to know that he doth not.

Bacon.

The words in the eighth verse *conferred* with the same words in the twentieth, make it manifest.

Raleigh.

Pliny *conferring* his authors, and comparing their works together, found those that went before transcribed by those that followed.

Broune.

Rest to the limbs, and quiet I *confer*
 On troubled minds.

Waller.

He was thought to *confer* with the lord Colepeper upon the subject; but had some particular thoughts, upon which he then *conferred* with nobody.

Clarendon.

The *conferring* this honor upon him would increase the credit he had.

Id.

Coronation to a king, *confers* no royal authority upon him.

South.

If we *confer* these observations with others of the like nature, we may find cause to rectify the general opinion.

Boyle.

The Christian princess in her tent *confers*
 With fifty of your learned philosophers;

Whom with such eloquence she does persuade,
 That they are captives to her reasons.

Dryden's Tyrannic Love.

There is not the least intimation in scripture of this privilege *conferred* upon the Roman church.

Tillotson.

Thou *conferrest* the benefits, and he receives them; the first produces love, and the last ingratitude.

Arbutnot's Hist. of John Bull.

— I shall say nothing at all to your mad present — you have so long and often been of important service to me; and I suppose you mean to go on *confering* obligations until I shall not be able to lift up my face before you.

Burns.

On Noah, and in him all mankind,
 The charter was *conferred*, by which we hold
 The flesh of animals in fee, and claim
 O'er all we feed on, power of life and death.

Cowper.

Much conversant with heaven, she often holds,
 With those fair ministers of light to man,
 That fill the skies nightly with silent pomp,
 Sweet *conference*.

Id.

It is not that I may not have incurred
 For my ancestral faults or mine the wound
 I bleed withal; and, had it been *conferred*
 With a just weapon, it had flowed unbound

Byron. Childe Harold.

CONFESS, *v. a. & v. n.* } Fr. *confesser*;
 CONFESSING, *n. s.* } It. *confessare*; Sp.
 CONFESSEDLY, *adv.* } *confesar*; Lat. *con-*
 CONFESSIO, *n. s.* } *fitere*. To disclose;
 CONFESSIO, *n. s.* } to acknowledge;
 CONFESSIO, *n. s.* } to own; to show; to
 CONFESSIO, *n. s.* } attest; to shrieve;
 CONFESSOR, *n. s.* } to admit to be
 CONFEST, *adj.* } true. Such are
 CONFESTLY, *adv.* } the meanings of
 CONFITENT, *n. s.* } the verb. Confes-

sion signifies the acknowledgment of a crime; avowal; a formulary, containing articles of faith. Confessor has the three-fold meaning of one who boldly avows his faith, at the risk of life or fortune; a priest, who shrieves a penitent; one who owns his crimes. The confessional and confessions denote the box in which the priest sits to hear the penitent. Confest, a poetical word for confessed, has the sense of open; acknowledged; undisputed; apparent. A confessary or confitent, is he who confesses anything.

Whosoever therefore shall *confess* me before men, him will I *confess* also before my Father which is in heaven; but whosoever shall deny me before men, him will I also deny before my Father which is in heaven,

Matt. x. 32, 33.

Who, before Pontius Pilate, witnessed a good *confession*.

1 Tim. vi. 13.

He must *confesse* him of all the conditions that belongeth to his sinne as forsoth as he can.

Chaucer. Cant. Tales.

Your owen mouth, by your *confession*,
 Hath damned you, and I wel it recorde.

Id.

Ful swetely herde he *confession*,
 And pleasant was his absolution,
 He was an esy man to give penance.

Id.

Whereto himself he did to witness call,
Who being askt, accordingly *confessed* all.

Spenser's Faerie Queene.

He doth in some sort *confess* it—If it be *confessed*, it is not redressed.

Shakspeare. Merry Wives of Windsor.

If that the king

Have any way your good deserts forgot,
Which he *confesseth* to be manifold,
He bids you name your griefs. *Id.*

Confess thee freely of thy sin ;
For to deny each article with oath,
Cannot remove nor choke the strong conception.

Id. Othello.

If there be one amongst the fair'st of Greece,
That loves his mistress more than in *confession*,
And dare avow her beauty and her worth
In other arms than hers ; to him this challenge.

Id. Troilus and Cressida.

See that Claudio

Be executed by nine-to-morrow morning ;
Bring him his *confessor*, let him be prepared ;
For that's the utmost of his pilgrimage.

Id. Measure for Measure.

The doctrine in the thirty-nine articles is so orthodoxly settled, as cannot be questioned without danger to our religion, which hath been sealed with the blood of so many martyrs and *confessors*.

Bacon's Advice to Villiers.

Your engaging me first in this adventure of the Moxa, and desiring the story of it from me, is like giving one the torture, and then asking his *confession*, which is hard usage. *Temple.*

They address to that principle which is *confestly* predominant in our nature. *Decay of Piety.*

If we directly *confess*, you must commend his ingenuity, and pardon the fault, be it what it will, and pardon it so, that you never so much as reproach him with it, or mention it to him again : for, if you would have him in love with ingenuity, and by a constant practise make it habitual to him, you must take care that it never procure him the least inconvenience ; but, on the contrary, his own *confession*, bringing always with it perfect impunity, should be, besides, encouraged with some marks of approbation. *Locke.*

I must *confess* I was most pleased with a beautiful prospect, that none of them have mentioned.

Addison on Italy.

In one of the churches I saw a pulpit and *confessional*, very finely inlaid with lapis-lazuli. *Id.*

The patience and fortitude of a martyr or *confessor* lie concealed in the flourishing times of Christianity.

Id. Spectator.

Our beautiful votary took the opportunity of *confessing herself* to this celebrated father. *Id.*

Tall thriving trees *confessed* the fruitful mold ;

The reddening apple ripens here to gold.

Pope's Odyssey.

Great geniusses, like great ministers, though they are *confessedly* the first in the commonwealth of letters, must be envied and calumniated.

Pope's Essay on Homer.

Human faults with human grief *confess* ;

'Tis thou art changed. *Prior.*

But wherefore should I seek

Since the peridious author stands *confest* ?

This villain has traduced me. *Rowe's Royal Conv.*

If our sin be only against God, yet to *confess* it to his minister may be of good use.

Wake's Preparation for Death.

I guess by the dear angel smile,

I guess by the love-rolling ee ;

But why urge the tender *confession*

'Gainst fortune's fell cruel decree—Jessy.

Burns.

How can I prevent all these arts of royal policy and all these displays of royal magnificence ? How can I prevent the successor of Frederick the Great from aspiring to a new, and, in this age, unexampled kind of glory ! Is it in my power to say that he shall not make his *confessions* in the style of St. Austin or of Rousseau ? *Burke*

Can a truth by all *confessed*

Of such magnitude and weight,

Grow, by being oft impressed,

Trivial as a parrot's prate ?

Cooper.

Harmonious speech, whose pure and liquid tone
Gives verse a music, scarce *confessed* its own ;
As light from gems assumes a brighter ray,
And clothed with orient lues, transcends the day.

Sheridan.

Long had the giant form on Gallia's plains
Inglorious slept, unconscious of his chains ;
Round his large limbs were wound a thousand strings,

By the weak hands of *confessors* and kings. *Darwin.*

From storms of hate thy mariner

And blast of chill indifference save,

So to thy power I'll frame the votive lay

And moored in Lesbia's arms *confess* thy sovereign

sway. *Id.*

Oh never yet beneath

The breast of man such trusty love may breathe !

That trying moment has at once revealed

The secret long, and yet but half concealed ;

In baring to revive that lifeless breast,

Its grief seemed ended—but the sex *confest*.

Byron. Lara.

Never at our vesper prayer.

Nor e'er before *confession* chair

Kneels he, nor reck he where arise

Incense or anthem to the skies,

But broods within his cell alone,

His faith and race alike unknown.

Id. The Giaour.

CONFESSION, among the Romish divines, has been advanced to the dignity of a sacrament. It is made to the priest, and is private and auricular. The priest is not to reveal what he hears in confession, under pain of the highest punishment. Catholics quote from the fathers, 'If the serpent, the devil, secretly bite a man, and thus infect him with the poison of sin, and this man still remain silent, and not do penance, nor be willing to make known his wound to his brother and master: the master who has a tongue that can heal, cannot be of service to him.' To which Protestants object that the priest is neither master nor physician in this case ; and is not competent to heal. The Romanists however add, 'The confession of sin is profitable [only] if amendment follow. For where is the use of showing the wound, if the medicine be not applied ?'

CONFESSION, in our law, is never to be divided, but always taken entire. A criminal is never condemned on his simple confession, without other collateral proofs ; nor is a voluntary extrajudicial confession admitted as any proof. A person is not admitted to accuse himself, according to that rule in law, *nemo auditur perire volens*.

CONFESSIOAL, or CONFESSIOALARY, was also a place in churches under the great altar,

where the bodies of deceased saints, martyrs, and confessors, were deposited.

CONFESSOR, in ecclesiastical history, the word is frequently used for martyr; in after times it was confined to those who, after having been tormented by the tyrants, were permitted to live and die in peace. And at last it was also used for those who, after having lived a good life, died under an opinion of sanctity.

CONFESSOR, in the Romish church, also gives absolution. The church calls him in Latin *confessarius*, to distinguish him from confessor, a name consecrated to saints. The confessors of the kings of France, from the time of Henry IV. were constantly Jesuits: before him the Dominicans and Cordeliers shared the office between them.

CONFICIENT, *adj.* Lat. *conficiens*. That which causes or brings about; having efficacy.

CONFIDE, *v. n. & a.* } Fr. *confier*; Ital. *confidarsi*; Sp. *confiar*. To put faith in; to trust implicitly, is the primary idea of to confide, and of all the words belonging to the same stock. Confidence, confident, and confidently, in some instances, are expressive of censure: they signify qualities, in themselves praiseworthy, carried to an excess; pushed into the limits of overbearingness or impudence. Confidential and confidentially, which imply an obligation to keep secret, are words of modern introduction; but are completely naturalised. A confidant is one who is entrusted with the secrets of the confider, and chiefly with those relating to love. Thus spelled, it is derived from the French, *confidant*. The English word *confident* has the same meaning.

Beloved, if our heart condemn us not, then have we confidence towards God. 1 John iii. 21.
Be merciful unto them which have not the confidence of good works. 2 Esd. viii. 36.
Be not confident in a plain way. Eccl. xxxii. 21,
— Submit you to high Providence,
And ever in your noble hart prevence,
That all the sorrow in the world is lesse
Than vertus's might, and value's confidence.

Spenser. Faerie Queene.
Yet stirred not at all for doubt of more,
But kept her place with courage confident. Id.
Sith only God surmounts all time's decay,
In God alone my confidence do stay.

Id. Visions of Ballay.
The fervent reprehenders of things established by public authority, are always confident and bold-spirited men; but their confidence, for the most part, riseth from too much credit given to their own wits, for which cause they are seldom free from errors.
Hooker. Dedication.
Both valiant, as men despising death; both confident, as unwonted to be overcome. *Sidney.*
Alas, my lord,
Your wisdom is consumed in confidence,
Do not go forth to-day.

Shakspeare. Julius Cæsar.
Douglas and the Hotspur, both together,
Are confident against the world in arms.
Id. Henry IV.

It is strange how the ancients took up experiments upon credit, and yet did build great matters upon them: the observation of some of the best of them, delivered confidently, is, that a vessel filled with ashes will receive the like quantity of water as if it had been empty; this is utterly untrue. *Bacon.*

Just confidence and native righteousness,
And honor. *Milton's Paradise Lost.*

He had an ambition and vanity, and a confidence in himself, which sometimes intoxicated, and transported, and exposed him. *Clarendon.*

I am confident that very much may be done towards the improvement of philosophy. *Boyle.*

People forget how little they know, when they grow confident upon any present state of things. *South.*

Society is built on trust, and trust upon confidence of one another's integrity. *Id.*

Every fool may believe, and pronounce confidently, but wise men will conclude firmly. *Id.*

It is preposterous, therefore, to sacrifice his innocency to the attaining of confidence, and some little skill of bustling for himself among others, by his conversation with ill-bred and vicious boys; when the chief use of that sturdiness, and standing upon his own legs, is only for the preservation of his virtue. *Locke.*

Aristotle was certainly a knowing man, but nobody ever thought him so, because he blindly embraced, and confidently vented, the opinions of another. *Id.*

Confidence is a plant of slow growth in aged bosoms. *Lord Chatham.*

He alone won't betray, in whom none will confide. *Congreve.*

Martin composed his billet-deux, and entrusted it to his confidant. *Arbuthnot and Pope.*

We shall not be ever the less likely to meet with success, if we do not expect it too confidently. *Atterbury.*

He may sacrifice the royalists of France, whom he had called to his standard, as a salutary example to those who shall adhere to their native sovereign, or shall confide in any other who undertakes the cause of oppressed kings and of loyal subjects. *Burke.*

It is an erect countenance; it is a firm adherence to principle; it is a power of resisting false shame and frivolous fear, that assert our good faith and honour, and assure to us the confidence of mankind. *Id.*

The man I trust, if shy to me,
Shall find me as reserved as he;
No subterfuge or pleading
Shall win my confidence again,
I will by no means entertain
A spy on my proceeding. *Cowper.*

Sweet moralist! afloat on life's rough sea,
The Christian has an art unknown to thee.
He holds no parley with unmanly fears;
Where duty bids he confidently steers,
Faces a thousand dangers at her call.

And, trusting in his God, surmounts them all. *Id.*
SIR BENJ.—To say truth, ma'am, 'tis very vulgar to print; and, as my little productions are mostly satires and lampoons on particular people, I find they circulate more by giving copies in confidence to the friends of the parties. *Sheridan. School for Scandal.*

CONFIGURATE, *v. n.* } Ital. *configurare*;
CONFIGURE, *v. a.* } Sp. *configurar*; Fr.
CONFIGURATION, *n. s.* } *configuration*; Ital. *configurazione*; Sp. *configuración*; Lat. *con* and *figura*. To configure is to adapt to a form; to configure is to show like the mutual aspects of the planets. Configuration signifies the figure of the parts of anything; the outline of a thing;

and also the conjunction, or mutual aspects of stars.

He that was sharp-sighted enough to see the *configuration* of the minute particles of the spring of a clock, and observe upon what peculiar structure and impulse its elastic motion depends, would no doubt discover something very admirable; but if eyes so framed could not view at once the hand and the characters of the hour-plate, and thereby at a distance see what o'clock it was, their owner could not be much benefited by that acuteness; which, whilst it discovered the secret contrivance of the parts of the machine, made him lose its use. *Locke.*

The different effects of fire and water, which we call heat and cold, result from the so differing *configuration* and agitation of their particles. *Glanville's Scepis.*

No other account can be given of the different animal secretions, than the different *configuration* and action of the solid parts. *Arbuthnot on Aliments.*

There is no plastic virtue concerned in shaping them, but the *configurations* of the particles whereof they consist. *Woodward.*

Mother earth brought forth legs, arms, and other members of the body, scattered and distinct, at their full growth; which coming together, cementing and so *configuring* themselves into human shape, made lusty men. *Bentley's Sermons.*

Ideas consist of synchronous motions or *configurations* of the extremities of the organs of sense. *Darwin.*

CONFINE, v. a. & n.	Fr. <i>confiner</i> ; Ital. <i>confinare</i> ; Span. <i>confinar</i> ; Lat. <i>confinis</i> . Limiting, circumscribing, retaining within certain bounds, is the master idea in all this class of words. To confine, therefore, is to enclose, to restrain within a definite space; to immure; to fasten to or up. A confiner is one who lives on the confines or frontiers of a country; or who is a near neighbour; also one who puts another into confinement; and it is applied to things as well as to persons. Confinity signifies proximity.
CONFINEDNESS, n. s.	
CONFINEMENT, n. s.	
CONFINER, n. s.	
CONFINABLE,	
CONFINITY, n. s.	

CONFINE, v. a. & n. Fr. *confiner*; Ital. *confinare*; Span. *confinar*; Lat. *confinis*. Limiting, circumscribing, retaining within certain bounds, is the master idea in all this class of words. To confine, therefore, is to enclose, to restrain within a definite space; to immure; to fasten to or up. A confiner is one who lives on the confines or frontiers of a country; or who is a near neighbour; also one who puts another into confinement; and it is applied to things as well as to persons. Confinity signifies proximity.

I'll not over the threshold.—
—Fy, you *confine* yourself most unreasonably:
Come, you must go visit the good lady. *Shakespeare. Coriolanus.*

I had been
As broad and general as the casing air;
But now I'm cabined, cribbed, *confined*, bound in. *Id.*

Here in these *confines* slyly have I lurked,
To watch the waining of mine enemies. *Id. Richard III.*

But that I love the gentle Desdemona,
I would not my unheused, free condition,
Put into circumscription and *confine*,
For the sea's worth. *Id. Othello.*

The senate hath stirred up the *confiners*. *Id. Cymbeline.*
Esteem him as a lamb, being compared
With my *confineless* harms. *Id. Macbeth.*

The particles or *confiners* between plants and living creatures are such as have no local motion; such as oysters. *Bacon.*

Half lost, I seek
What readiest path leads where your gloomy bounds
Confine with heaven. *Milton's Paradise Lost.*

All bodies are *confined* within some place,
But she (the soul) all place within herself *confines*. *Davies.*

Happy *confiners* you of other lands,
That shift your soil. *Daniel's Civil War.*

Where honour or where conscience does not bind,
No other tie shall shackle me;
Slave to myself I will not be;
Nor shall my future actions be *confined*
By my own present mind. *Cowley.*

Though gladness and grief be opposite in nature,
yet they are such neighbours and *confiners* in art, that
the least touch of a pencil will translate a crying into
a laughing face. *Wotton.*

Make one man's fancies, or failings, *confining* laws
to others, and convey them as such to their successors. *Boyle.*

The idea of duration, equal to a revolution of the
sun, is applicable to duration, where no motion was;
as the idea of a foot, taken from bodies here, to distances
beyond the *confines* of the world, where are no
bodies. *Locke.*

He is to *confine* himself to the compass of numbers,
and the slavery of rhyme. *Dryden.*

Full in the midst of this created space,
Betwixt heaven, earth, and skies, there stands a place
Confining on all three. *Id.*

Our hidden foes,
Now joyful from their long *confinement* rose. *Dryden's Virgil.*

'Twas ebbing darkness, past the noon of night,
And Phosphor on the *confines* of the light. *Id. Fables.*

The mind hates restraint, and is apt to fancy itself
under *confinement* when the sight is pent up. *Addison.*

No subtle nor superfluous lore he sought,
Nor ever wished his Edwin to pursue,
'Let man's own sphere,' said he, '*confine* his view
Be man's peculiar work his sole delight.' *Beattie.*

Even to those persons whose mode of observation
are *confined* within a narrow circle, the exercise of the
necessary arts may open inexhaustible sources of
amusement, to alleviate the cares of a solitary and
laborious life. *Id.*

After six weeks *confinement* I am beginning to walk
across the room. They have been six horrible weeks;
anguish and low spirits made me unfit to read, write,
or think. *Burns.*

Peace be the lot of the mind
That's lock'd in meekness and love:
But rapture and bliss are *confined*
To the spirit'd spirits above. *Cowper.*

Yet Leulin' lik' the late though Orpheus strang
His lyre to stann' divine, its amorous lord
For thee had left Eurydic' unsung,
And Pluto's gloomy *confines* unexplor'd. *Hudibras.*

CONFIRM, v. a.	Fr. <i>confirmer</i> ; It. <i>confirmare</i> ; Span. <i>confirmar</i> ; Lat. <i>confirmare</i> . To make stable; to fix beyond doubt; to strengthen; to settle; to perfect; are the ideas conveyed by the verb to confirm. These meanings are attached to all its kindred words, which, therefore, it is needless to define. See CONFIRMATION.
CONFIRMABLE, adj.	
CONFIRMANCE, n. s.	
CONFIRMATION, n. s.	
CONFIRMATIVE, adj.	
CONFIRMATOR, n. s.	
CONFIRMATORY, adj.	

CONFIRMATION, n. s. To make stable; to fix beyond doubt; to strengthen; to settle; to perfect; are the ideas conveyed by the verb to confirm. These meanings are attached to all its kindred words, which, therefore, it is needless to define. See CONFIRMATION.

I confirm thee in the high priesthood, and appoint thee ruler. *I Macc. xi. 57.*
The testimony of Christ was *confirmed* in you. *I Cor. i. 6.*

Ye that have not chosen in humble wise,
Without repenting, cheseth now your make,
Yet at the lest renoveleth your service,
And ye that have full chosen, as I devise,
Confermeth it perpetually to dure. *Chaucer.*

I consent, and *confirme* every del
Your wordes all, and your opinion.

Id. Cant. Tales.

And to *confirmin* my resonne
Thou wotist wel that speche is sowene,
Or ellis no man might it here.

Id. House of Fame.

So settled he his kingdome, and *confirmed* his right.

Spenser's Faerie Queene.

Confirm the crown to me and to mine heirs.

Shakspeare. Henry VI.

He only lived but till he was a man :

The which no sooner had his prowess *confirmed*,

But like a man he died. *Id. Macbeth.*

Be these sad sighs *confirmers* of thy words ?

Then speak again. *Id. King John.*

Embrace and love this man.—

— With brother's love I do it.—

— And let heaven

Witness how dear I hold this *confirmation*!

Id. Henry VIII.

The sea-captains answered, that they would perform his command ; and in *confirmation* thereof promised not to do any thing which besemed not valiant men.

Knolles's History.

So was his will
Pronounced among the gods, and by an oath,
Which shook heaven's whole circumference, *confirmed.*

Milton.

Confirmed then I resolve,

Adam shall share with me in bliss or woe. *Id.*

There wants herein the definitive *confirmator*, and test of things uncertain, the sense of man. *Brown.*

Wanting frequent *confirmation* in a matter so confirmable, their affirmation carrieth but slow persuasion. *Id.*

It may receive a spurious inmate, as is *confirmable* by many examples. *Id.*

What is prepared for in catechising, is, in the next place, performed by *confirmation* ; a most profitable usage of the church, transcribed from the practice of the apostles. *Id.*

The arguments brought by Christ for the *confirmation* of his doctrine, were in themselves sufficient.

South.

If the difficulty arise from the *confirmedness* of habit, every resistance weakens the habit, abates the difficulty. *Decay of Piety.*

These divisions also have given occasion to the reading these epistles by parcels, and in scraps, which has farther *confirmed* the evil arising from such partitions. *Locke.*

Whilst all the stars that round her burn,

And all the planets in their turn,

Confirm the tidings as they roll,

And spread the truth from pole to pole.

Addison's Spectator.

That treaty, so prejudicial, ought to have been re-mitted rather than *confirmed.* *Swift.*

But martyrs struggle for a brighter prize,

And win it with more pain. Their blood is shed

In *confirmation* of the noblest claim,

Our claim to feed upon immortal truth,

To walk with God, to be divinely free,

To soar, and to anticipate the skies. *Cowper.*

Chained to the chariot of triumphal Art,

We stand as captives, and would not depart.

Away!—there need no words, nor terms precise,
The paltry jargon of the marble mart,

Where Pedantry gulls Folly—we have eyes :
Blood—pulse—and breast, *confirm* the Dardan shep-
herd's prize. *Byron. Child Harold.*

CONFIRMATION, in law, a conveyance of an estate, or right in esse, from one man to another, whereby a voidable estate is made sure and unavoidable, or a particular estate is increased, or a possession made perfect.

CONFIRMATION, in the established church, is the ceremony of laying on of hands. In the primitive church it was administered, we are told, after baptism, if the bishop happened to be present. Throughout the East, it still accompanies baptism ; but the Romanists make it a distinct independent sacrament ; and the person to be confirmed, has a god-father and god-mother appointed him, as in baptism.

CONFISCATE, *v. a. & adj.* } Fr. *confis-*
CONFISCATION, *n. s.* } *quer* ; It. *con-*
CONFISCATOR, *n. s.* } *fiscare* ; Span. }
CONFISCATORY, *adj.* } *confiscar.* To

confiscate is for the prince to seize, to his own use, the property of the subject, as the penalty of some crime, really or pretendedly committed. It is a common resource of tyrants, and numerous modern examples of it have been afforded by Spain, under the dominion of the worthless Ferdinand. The origin of the word is thus traced by Cowel. ' Confiscare, confisquer, i. e. in publicum addicere ; from fiscus, which originally signifieth a hamper, pannier, basket, or freil ; but metonymically the emperor's treasure, because it was anciently kept in such hampers.' Shakspeare uses the adjective, *confiscate*, with the accent on the first syllable.

Thy lands and goods

Are, by the laws of Venice, *confiscate*

Unto the state of Venice.

Shakspeare. Merchant of Venice.

It was judged that he should be banished, and his whole estate *confiscated* and seized, and his houses pulled down. *Bacon.*

It was in every man's eye, what great forfeitures and *confiscations* he had at that present to help himself. *Id. Henry VII.*

Whatever fish the vulgar fry excel,
Belong to Cæsar, wheresoe'er they swim,
By their own worth *confiscated* to him.

Dryden's Juvenal.

So that no constitution fancier may go unsuited from his shop, provided he loves a pattern of pillage, oppression, arbitrary imprisonment, *confiscation*, exile, revolutionary judgment, and legalised premeditated murder, in any shapes into which they can be put.

Burke.

I see the *confiscators* begin with bishops, and chapters, and monasteries ; but I do not see them end there. *Id.*

Those terrible *confiscatory* periods. *Id.*

He fished

For wandering merchant vessels, now and then,

And sometimes caught as many as he wished ;

The cargoes he *confiscated*, and gain

He sought in the slave-market too, and disbed

Full many a morsel for that Turkish trade,

By which, no doubt, a good deal may be made.

Byron. Don Juan.

CONFIT, *n. s.* } Fr. *confit*; Ital. *con-*
CONFITURE, *n. s.* } *fetta*; Sp. *confite*; Lat.
confectura. A confit; a sweetmeat; a con-
fection.

It is certain, that there be some houses wherein
confitures and pies will gather mould more than in
others. *Bacon*.

We contain a *confiture* house, where we make all
sweetmeats, dry and moist, and divers pleasant
wines. *Id.*

Would you not use me scurvily again, and give me
possets with purging *confits* in't?

Beaumont and Fletcher.

CONFIX, *v. a.* } Lat. *configo*, *confixum*;
CONFIXURE, *n. s.* } To fix down; to fasten;
the act of fastening.

As this is true,

Let me in safety raise me from my knees;
Or else for ever be *confixed* here,
A marble monument!

Shakspeare. Measure for Measure.

CONFLAGRANT, *adj.* } Fr. *conflagration*;
CONFLAGRATION, *n. s.* } It. *conflagrazione*;
Sp. *conflagracion*; Lat. *conflagrans*, *conflagratio*.
Conflagration signifies a widely extended fire;
conflagrant, burning together; being involved in
a general fire.

The opinion deriveth the complexion from the de-
viation of the sun, and the conflagration of all things
under Phaeton. *Brocue's Vulgar Errors.*

Then raise

From the *conflagrant* mass, purged and refined,
New heavens, new earth. *Milton's Paradise Lost.*

Next o'er the plains, where ripened harvests grow,
The running *conflagration* spreads below.

Milton's Ovid.

Mankind hath had a gradual increase, notwith-
standing what floods and *conflagrations*, and the re-
ligious profession of celibacy, may have interrupted.

Bentley's Sermons.

A *conflagration*, or a wintry flood,
Has left some hundreds without home or food:
Extravagance and avarice shall subsistible,
While fame and self complacence are the bribe.

Cowper.

CONFLAGRATION OF THE WORLD. The ancient
Pythagoreans, Platonists, Epicureans, and Stoics,
appear to have had a notion of the general con-
flagration: though whence they should have
derived it, unless from the sacred books, it is
difficult to conceive; except, perhaps, from the
Phœnicians, who had it from the Jews. Seneca
says expressly, *Tempus advenit quo sidera*
sideribus incurrent, et omni flagrante materia
uno igne, quicquid nunc ex deposito lucet arde-
bit. This general dissolution the Stoics call
εκπρωσις, *ecpyrosis*. Mention of the conflagra-
tion is also made in the books of the Sybils,
Sophocles, Hystaspes, Ovid, Lucan. &c. Dr.
Burnet says, the Siamese believe that the earth
will at last be parched up with heat; the moun-
tains melted down; the earth's whole surface
reduced to a level, and then consumed with fire.
And the brahmins of Siam not only hold that the
world shall be destroyed by fire, but also that a
new earth shall be made out of it. Various are
the sentiments of authors on the subject of the
conflagration; the cause whence it is to arise,
and the effects it is to produce.

CONFULATE, *adj.* } Lat. *confutum*. The
CONFULATION, *n. s.* } Act of blowing many in-
struments together; also casting of metal.

The sweetest harmony is, when every part or in-
strument is not heard by itself, but a *confulation* of
them all. *Bacon*.

CONFLEXURE, *n. s.* Lat. *conflexura*. A
bending or turning.

CONFLICT, *v. n.* } Fr. *conflict*; Ital.
CONFLICT, *n. s.* } *confitto*; Span. *con-*

CONFLICTATION, *n. s.* } *flicto*; Lat. *configo*,
conflictus. To fight; to contend; to strive ar-
dently; to dash together. Violent collision;
combat; strife; pangs of body or mind. Con-
flictation is synonymous with conflict; but it is
obsolete.

And each one taking part in other's aid,
This cruel *conflict* raised thereabout
Whose dangerous success depended yet in doubt.

Spenser's Faerie Queene.

O! what a sight it was wistly to view
How she came stealing to the wayward boy;
To note the fighting *conflict* of her hue,
Hew white and red each other did destroy.

Shakspeare. Venus and Adonis.

Bare unhooused trunks,
To the *conflicting* elements exposed,
Answer me nature.

Id. Timon.

No assurance touching victories can make present
conflicts so sweet and easy, but nature will shrink
from them. *Hooker.*

You shall hear under the earth a horrible thunder-
ing of fire and water *conflicting* together.

Bacon's Natural History.

Pour dephlegmed spirit of vinegar upon salt of tar-
tar, and there will be such a *conflict* or ebullition, as
if there were scarce two more contrary bodies in
nature. *Boyle.*

A man would be content to strive with himself,
and *conflict* with great difficulties, in hopes of a mighty
reward. *Tillotson.*

He perceived

The unequal *conflict* then, as angels look
On dying saints. *Thomson.*

Lashed into foam, the fierce *conflicting* brine
Seems o'er a thousand raging waves to burn. *Id.*

He said no more, for in his breast
Conflicting thoughts the voice suppressed:
The ire of vengeance seemed to stream
From his swollen eyeballs' yellow gleam. *Beattie.*

These opposed and *conflicting* interests, which you
considered as so great a blemish in your old and in
our present constitution, interpose a salutary check to
all precipitate revolutions. *Burke.*

He that wrestles with us, strengthens our nerves,
and sharpens our skill. Our antagonist is our helper.
This amicable *conflict* with difficulty obliges us to an
intimate acquaintance with our object, and compels
us to consider it in all its relations. It will not suffer
us to be superficial. *Id.*

Every speck

Seen in the dim horizon turns thee pale
With *conflict* of contending hopes and fears.
But comes at last the dull and dusky eve,
And sends thee to thy cabin, well prepared,
To dream all night of what the day denied.

Cowper.

Hark! heard you not those hoofs of dread? note?
Sounds not the clang of *conflict* on the heath?
Saw ye not whom the reeking sabre smote;
Nor saved your brethren ere they sank beneath
Tyrants and Tyrant's slaves? *Byron's Child Harold.*

CONFLOW, *v. n.* } Fr. *confluent*; It.
 CONFLUENT, *n. s.* } *confluente*; Sp. *con-*
 CONFLUENT, *adj.* } *fluir, confluencia*;
 CONFLUOUS, *adj.* } Lat. *confluere*. Hol-
 CONFLUENCE, *n. s.* } land, the translator,
 CONFLUIBILITY, *n. s.* } as the Encyclopædia
 CONFLUIBLENESS, *n. s.* } Metropolitana ob-
 serves, seems to be the only writer who has used the
 verb *conflow*; it was probably coined by him; and
 it deserves a place in our language. Confluence
 and *conflux* signify the junction of streams; the
 crowding of people to one spot; the multitude
 so formed; the concurring together of several
 circumstances to one end. Confluent and con-
 fluent mean running one into another. Boyle
 employs the word *confluxibility* to express a ten-
 dency to form a junction by flowing together.

You see this *confluence*, this great flood of visitors.
Shakespeare.

Knots, by the *conflux* of meeting sap,
 Infect the sound pine and divert his grain. *Id.*

Nimrod, who usurped dominion over the rest, sat
 down in the very *confluence* of all those rivers which
 watered Paradise. *Raleigh's History of the World.*

Some come to make merry, because of the *con-*
fluence of all sorts. *Bacon.*

You had found by experience the trouble of all
 men's *confluence*, and for all matters to yourself.
Bacon to Villiers.

To the gates east round thine eye, and see
 What *conflux* issuing forth, or entering in. *Milton.*

He quickly by the general *conflux* and course of
 the whole people, streightened his quarters.
Clarendon.

We may there be instructed how to rate all goods
 by those that will concentrate into the felicity we shall
 possess, which shall be made up of the *confluence*,
 perfection, and perpetuity of all true joys. *Boyle.*

This will draw a *confluence* of people from all parts
 of the country. *Temple.*

Let us, to make their various currents one,
 Be congregated floods together run:

These *confluent* streams make some great river's
 head,
 By stores still melting and descending fed.
Blackmore.

In the veins, innumerable little rivulets have their
confluence into the great vein, the common channel
 of the blood. *Bentley.*

Thus where the veins their *confluent* branches bend,
 And milky eddies with the purple blend;
 The chyle's white trunk, diverging from its source,
 Seeks through the vital mass its shining course.
Darwin.

CONFORM, *v. a. & n., & adj.* } Fr. *confor-*
 CONFORMABLE, *adj.* } *mer*; It. *con-*
 CONFORMABLY, *adv.* } *formare*; Sp.
 CONFORMATION, *n. s.* } *conformar*;
 CONFORMER, *n. s.* } Lat. *confor-*
 CONFORMIST, *n. s.* } *mare*. Min-
 CONFORMITY, *n. s.* } shew, (No.

2294), gives the radical meaning with great clear-
 ness. 'To conforme,' says he, 'Lat. *conformare*,
 à *con* and *formare*, q. eandem formam rei alicui
 imponere.' Accordingly, to conform signifies, in
 its active senses, to reduce to a similar appearance,
 shape, manner, or opinion, with something else;
 and in its neuter sense; to give way; to comply
 with. That which has been so reduced becomes
 conformable *to* or *with*; acts conformably *to*, or

in conformity *with*, the agent by which the re-
 duction has been effected. Conform, as an
 adjective, means having a similarity to; being
 in consonance with. Conformation indicates the
 act of fashioning, or ordering a thing; the par-
 ticular texture and consistence of the parts of a
 body; and the act of producing suitability to
 anything. A conformer, or conformist, is one
 who conforms, who submits to; the words are
 particularly used with reference to the established
 church.

And then *conforming* it unto the light,
 Which in itself it hath remaining still,
 Of that first sun, yet sparkling in his sight.
Spenser.

Demand of them wherefore they *conform* not them-
 selves unto the order of the church? *Hooker.*

For all the kingdoms of the earth to yield them-
 selves willingly *conformable*, in whatever should be re-
 quired, it was their duty. *Id.*

By the knowledge of truth, and exercise of virtue,
 man, amongst the creatures of this world, aspireth to
 the greatest *conformity* with God. *Id.*

I've been to you a true and humble wife,
 At all times to your will *conformable*.
Shakespeare's Henry VIII.

Then followed that most natural effect of *conforming*
 one's self to that which she did like. *Sidney.*

Variety of tunes doth dispose the spirits to variety
 of passions *conform* unto them.
Bacon's Natural History.

Judge not what is best
 By pleasure, though to nature seeming meet;
 Created as thou art to nobler end,
 Holy and pure, *conformity* divine!

Milton's Paradise Lost.
Conformity in building to other civil nations, hath
 disposed us to let our old wooden dark houses fall to
 decay. *Grant.*

Whatsoever should thus be universally useful, as a
 standard to which men should *conform* their manners,
 must have its authority either from reason or revela-
 tion. *Locke;*

Printers, binders, sellers, and others that make a
 trade, and gain out of them (books), have universally
 so odd a turn and corruption of mind, that they have
 a way of dealing peculiar to themselves, and not *con-*
formed to the good of society, and the general fairness
 that cements mankind. *Id.*

Such a law of morality Jesus Christ hath given us
 in the New Testament, but by the latter of these ways,
 by revelation. We have from him a full and sufficient
 rule for our direction, and *conformable* to that of
 reason. *Id.*

So a man observe the agreement of his own
 imaginations, and talk *conformably*, it is all certainty.
Id.

The dissenting congregations are supposed by their
 teachers to be more accurately instructed in the
 matters of faith, and better to understand the Christian
 religion, than the vulgar *conformists*, who are charged
 with great ignorance—how truly I will not here de-
 termine. *Id.*

Among mankind so few there are,
 Who will conform to philosophic fare.
Dryden's Juvenal.

We cannot be otherwise happy but by our *conformity*
 to God. *Tillotson.*

Many instances prove the *conformity* of the essay
 with the notions of Hippocrates.

Arbuthnot on Aliments.

Where there happens to be such a structure and *conformation* of the earth, as that the fire may pass freely into these spiracles, it then readily gets out.

Woodward's Natural History.

The productions of a great genius, with many lapses, are preferable to the works of an inferior author, scrupulously exact, and *conformable* to all the rules of correct writing.

Addison.

The fragments of Sappho give us a taste of her way of writing, perfectly *conformable* with that character we find of her.

Id.

I have treated of the sex *conformably* to this definition.

Id.

This metaphor would not have been so general, had there not been a *conformity* between the mental taste and the sensitive taste.

Id.

Virtue and vice, sin and holiness, and the *conformation* of our hearts and lives to the duties of true religion and morality, are things of more consequence than the furniture of understanding.

Watts.

It is not your fond desires or mine that can alter the nature of things; by contending against which, what have we got, or shall ever get, but defeat and shame? I did not obey your instructions: no, I *conformed* to the instructions of truth and nature, and maintained your interest against your opinions, with a constancy that became me.

Burke.

Through the same plan of a *conformity* to nature in our artificial institutions, and by calling in the aid of her unerring and powerful instincts, to fortify the fallible and feeble contrivances of our reason, we have derived several other, and those no small benefits, from considering our liberties in the light of an inheritance.

Id.

CONFORT, *v. a.* } Fr. *conforter*; low
CONFORTATION, *n. s.* } Latin, *conforto*. To
CONFORTATIVE, *adj.* } strengthen; to comfort;
CONFORTATORY, *us.* } to act as a corroborative. Obsolete.

For corroboration and *confortation*, take such bodies as are of an astringent quality, without manifest cold.

Bacon's Natural History.

CONFOUND, *v. a.* } Fr. *confondre*;
CONFOUNDED, *part. adj.* } Ital. *confondere*;
CONFOUNDEBLY, *adv.* } Sp. *confundir*;
CONFOUNDEDNESS, *n. s.* } Lat. *confundere*.
CONFUNDER, *n. s.* } *à con* and *fundere*, to powre out, i. e. to powre out one with another, says Minshew. To commingle things in such a manner that the separate parts can no longer be distinguished, is here the primary idea. Hence, to confound, means, to render indistinct, or unintelligible; to involve in perplexity; to deprive of the power of distinguishing; to astonish; to throw into consternation; to destroy; to subvert. Confounded and confoundedly are low words, never used but in familiar speech, or ludicrous composition. They indicate that which is hateful or shameful.

Let us go down, and there *confound* their language, that they may not understand one another's speech.

Gen. xi. 7.

Let them be *confounded* in all their power and might, and let their strength be broken.

Daniel, xxi.

O scathful harm, condition of poverty,
With thirst, with cold, with hunger so *confounded*.

Chaucer's Cant. Tales.

O feined woman all that may *confound*
Vertue and innocence, thurgh thy malice
Is bred in thee, as nest of every vice.

Id.

So gan he to disclose the whole debate,
Which that straunge knight for him sustained had,
And these two Sarazins *confounded* late.

Spenser's Faerie Queene.

But soone the knights with their bright burning
blades

Broke their rude troupes, and orders did *confound*.

Id.

The gods *confound* thee! dost thou hold there still?

Shakspeare.

The sweetest honey

Is loathsome in its own deliciousness,
And in the taste *confounds* the appetite.

Id.

Crooked eclipses 'gainst his glory fight,
And time, that gave, doth now his gift *confound*.

Id. Sonnet 1x.

Wrapt and *confounded* in a thousand fears,
Like to a new-killed bird she trembling lies.

Id. Rape of Lucrece.

A thousand sparkling stars about her shone;
But she herself did sparkle more alone
Than all those thousand beauties would have done,
If they had been *confounded* all in one.

Davies.

So deep a malice to *confound* the race
Of mankind in one root.

Milton.

Two planets rushing from aspect malign,
Of fiercest opposition, in mid sky
Should combat, and their jarring spheres *confound*.

Id.

So spake the Son of God; and Satan stood
A while as mute, *confounded* what to say

Id. Paradise Regained.

I am yet to think, that men find their simple ideas
agree, though, in discourse, they *confound* one another
with different names.

Locke.

They who strip not ideas from the marks men use
for them, but *confound* them with words, must have
endless dispute.

Id.

A most *confounded* reason for his brutish conception.

Grew.

Thy speculations begin to smell *confoundedly* of
woods and meadows.

Addison's Spectator.

Now with furies surrounded,
Despairing, *confounded*,

He trembles, he glows,
Amidst Rhodope's snows.

Pope's St. Cecilia.

Sir, I have heard another story:
He was a most *confounded* Tory;

And grew, or he is much belied,
Extremely dull before he died.

Swift.

Sighs from a breaking heart my voice *confound*;
With trembling step, to join you weeping train
I haste, where gleams funereal glare around,
And mixed with shrieks of woe, the knells of death
resound.

Beattie.

Under misfortunes it often happens that the nerves
of the understanding are so relaxed, the pressing peril
of the hour so completely *confounds* all the faculties,
that no future danger can be properly provided for,
can be justly estimated, can be so much as fully seen.

Burke.

Cold, temperate, and torrid clime
Sees her infuriate lust of crime
Burst every social bond, *confound*
Order, spread insurrection round.

Hudibras.

But haughty still, and loth himself to blame,
He called on Nature's self to share the shame,
And charged all faults upon the fleshly form
She gave to clog the soul, and feast the worm;
Till he at last *confounded* good and ill,
And half mistook for fate the acts of will.

Byron. Lara.

CONTRACT, *part.* Lat. *contractum*. Broken.

CONFRATERNITY, *n. s.* Lat. *con* and *fraternitas*. A brotherhood; a body of men united for some religious purpose.

We find days appointed to be kept, and a *confraternity* established for that purpose, with the laws of it. *Stillingfleet.*

CONFRICATION, *n. s.* Lat. *con* and *frico*.

The act of rubbing against anything.

It hath been reported, that ivy hath grown out of a stag's horn; which they suppose did rather come from a *confrication* of the horn upon the ivy, than from the horn itself. *Bacon.*

CONFRIER, *n. s.* Fr. *confreirc*. One of the same religious order.

CONFRONT, *v. a.*

CONFRONTATION, *n. s.* } Fr. *confronter*; Ital.

CONFRONTER, *n. s.* } *confrontare*; Sp. *con-*

frontar. To stand, or cause to stand, face to face; to oppose one evidence to another in open court; to compare one thing with another. The act of bringing two evidences face to face. The person who confronts.

The East and West churches did both *confront* the Jews, and concur with them. *Hooker.*

Blood hath bought blood, and blows have answered blows,

Strength matched with strength, and power *confronted* power. *Shakespeare. King John.*

We began to lay his unkindness unto him: he, seeing himself *confronted* by so many, went not to denial, but to justify his cruel falsehood. *Sidney.*

He spoke, and then *confronts* the bull;

And on his ample forehead, aiming full,

The deadly stroke descended. *Dryden's Virgil.*

When I *confront* a medal with averse, I only shew you the same design executed by different hands.

Addison on Medals.

The argument would require a great number of comparisons, *confrontations*, and combinations, to find out the connexion between the two manners. *Swinburne.*

CONFUCIUS, or CONG-FU-TSE, the greatest of the Chinese philosophers, whose memory is cherished as that of a saint, was born in the kingdom of Lu, now the province of Chang-tong, about 550 years before the birth of Christ: by which he seems to have been prior to Socrates, and contemporary with Pythagoras and Solon. At a very early period of life he gave proofs of uncommon talents; and being a descendant of the imperial family of the Chang dynasty, he was put under the ablest tutors, for cultivating and improving them. He had scarcely arrived at the years of maturity, when he evinced his acquaintance with all the literature of that era, particularly the canonical and classical books, ascribed to the legislators Yao and Chun. He had naturally an agreeable temper; and was distinguished for humility, sincerity, and disinterestedness; moderating his appetites, and contemning riches. He embraced, we are told, every opportunity afforded by the important station which he occupied in the kingdom of Lu, to estimate exactly the state of morals among his countrymen, and though he found them extremely vicious, formed and succeeded in the idea of a general reformation of morals. The torrent of corruption and depravity however returned; or Confucius became like many other reformers unreasonable and impatient in his expectations. At any rate he left Lu, in

the hopes of succeeding better in some distant kingdom; but, finding virtue everywhere overwhelmed by vice, he adopted the more humble employment of a teacher of youth, and trained, it is said, above 3000 scholars. He divided his doctrines into four parts, and his disciples into four classes: 1. Those who studied the moral virtues; 2. Those who studied the art of reasoning and public speaking; 3. Those who studied law and government; 4. Those who studied eloquence. He terminated his career in the seventy-second year of his age. His works are, 1. Tay-hio, i. e. The Grand Science, or school of adults, inculcating the duties of self-government, and obedience to the laws of right reason; 2. The Chong-yong, or the Immutable Medium; 3. Lung-yu, or Moral and Pithy Discourses; 4. Meng-tse, or the Book of Mencius; so named from one of the disciples, who is said to have completed it from his master's writings. There are also Hyau-king, treating of the respect due from children to their parents; and lastly, The Syau-hys, sentences, maxims, and examples, extracted from ancient and modern authors. His religion appears to have been that of pure theism. Numerous structures are raised to his honor in China: his books are regarded by the Chinese as the fountain of wisdom, and his descendants enjoy to this day the title of mandarins of the first order. See our article CHINA.

CONFUSE, *v. a. & adj.*

CONFUSED, *adj.*

CONFUSEDLY, *adv.*

CONFUSEDNESS, *n. s.*

CONFUSELY, *adv.*

CONFUSION, *n. s.*

CONFUSIVE, *adj.*

Fr. *confus*; It. and Sp. *confuso*; Lat. *confusus*. — Confuse is from the same root as confound, and is closely allied to it in meaning. To confuse is to throw into disorder; to perplex; to render intricate; to deprive of the power of discerning and discriminating. Confusion signifies disorderly mixture; disarray; tumult; want of clearness in the ideas; hurry of ideas; amazement; distraction of mind; overthrow; destruction. The sense of the congenerous words is too obvious to require being defined.

Min herte may min harmes not bewrey;

I am so *confuse* that I cannot say.

Chaucer. Cant. Tales.

Alas! ybrought is to *confusion*

The blood real of Cadme and Amphion. *Id.*

A rout of people they before them bend,

Flocking together in *confuse* array,

As if that there were some tumultous afrray.

Spenser. Faerie Queenc.

Where when *confusedly* they came, they fownd

Their lady lying on the sencelesse ground. *Id.*

God is not a God of sedition and *confusion*, but of

order and of peace. *Hooker. Preface.*

These four nations are every where mixed in the

Scriptures, because they dwell *confusedly* together.

Raleigh's History.

This is a happier and more comely time,

Than when these fellows ran about the streets

Crying *confusion*. *Shakespeare. Coriolanus.*

The strength of their illusion,

Shall draw him in to his *confusion*.

Id. Macbeth.

God only wise, to punish pride of wit,
 Amongst men's wits hath this *confusion* wrought,
 As the proud tower whose points the clouds did hit,
 By tongues *confusion* was to ruin brought. *Davies.*

Thus roving on
 In *confused* march forlorn, the adventurous bands
 Viewed first their lamentable lot, and found
 No rest. *Milton.*

He *confusedly* and obscuredly delivered his opinion. *Clarendon.*

The *confusion* of two different ideas, which a customary connexion of them in their minds hath made to them almost one, fills their heads with false views, and their reasonings with false consequences. *Locke.*

The propriety of thoughts and words, which are the hidden beauties of a play, are but *confusedly* judged in the vehemence of action. *Dryden.*

Confusion dwelt in every face,
 And fear in every heart,
 When waves on waves, and gulphs in gulphs,
 O'ercame the pilot's art. *Spectator.*

I viewed through a prism, and saw them most *confusedly* defined, so that I could not distinguish their smaller parts from one another. *Newton's Optics.*

The cause of the *confusedness* of our notions, next to the natural inability, is want of attention. *Norris.*

We may have a clear and distinct idea of the existence of many things, though our ideas of their intimate essences and causes are very *confused* and obscure. *Watts's Logic.*

Can mortal strength presume to soar so high!
 Can mortal sight, so oft bedimmed with tears,
 Such glory bear!—for lo, the shadows fly
 From Nature's face; *confusion* disappears,
 And order charms the eye, and harmony the ears!
Beattie.

And now the tumults of the war,
 Mingling *confusedly* from afar. *Id.*

The nobility and the clergy, the one by profession, the other by patronage, kept learning in existence, even in the midst of arms and *confusions*, and whilst governments were rather in their causes than formed. *Burke.*

I saw thee gaze upon my face,
 Yet met with no *confusion* there:
 One only feeling couldst thou trace—
 The sullen calmness of despair. *Byron.*

CONFUSION, in a logical sense, is opposed to distinctness, or perspicuity; and may happen either in words, as when misconceived or misapplied; or in ideas, as when the idea of any thing presents something along with it, which does not properly belong to that thing. See **IDEA** and **NOTION**.

CONFUSION, in a physical sense, is a sort of union or mixture by mere contiguity. Such is that between fluids of contrary natures, as oil and vinegar, &c.

CONFUTE, *v. a. & n. s.* } Fr. *confuter*;
CONFUTEMENT, *n. s.* } It. *confutare*; Sp.
CONFUTER, *n. s.* } *confutar*; Lat.
CONFUTABLE, *ad.* } *confutare*. To
CONFUTANT, *n. s.* } convict of error;
CONFUTATION, *n. s.* } to disprove the
CONFUTATIVE, *ad.* } arguments or as-
 sertions of an antagonist. The confuter, or confutant, is the person who accomplishes the confutation, or confutement, of the confutable assertions. Confutative signifies that which confutes.

At the last day, that inquisitor shall not present to God a bundle of calumnies, or *confutable* accusations; but will offer unto his omniscience a true list of our transgressions. *Browne.*

Now that the *confutant* may also know, as he desires, what force of teaching there is sometimes in laughter. *Milton.*

An opinion held by some of the best among reformed writers, without scandal or *confutement*. *Id.*

We have promised that their own dearest doctors and divines should be their *confuters*. *Bishop Morton.*

He could on either side dispute;
Confute, change hands, and still *confute*. *Hudibras.*

For a man to doubt whether there be any hell, and thereupon to live as if there were none, but, when he dies, to find himself *confuted* in the flames, must be the height of woe. *South.*

Man, 'tis true,
 Smit with the beauty of so fair a scene,
 Might well suppose the Artificer divine
 Meant it eternal, had he not himself
 Pronounced it transient, glorious as it is,
 And, still designing a more glorious far,
 Doomed it as insufficient for his praise.
 These therefore are occasional, and pass;
 Formed for the *confutation* of the fool,
 Whose lying heart disputes against a God;
 That office served, they must be swept away. *Cowper.*

CONFUTATION, in rhetoric, &c. part of an oration, wherein the orator strengthens his cause by destroying the opposite arguments of his antagonist; by denying what is apparently false, by detecting some flaw in the reasoning of the adverse party, by granting his argument, and showing its invalidity, or retorting it upon the adversary.

CONGAREE, a considerable river of South Carolina, formed by the confluence of the Saluda and Broad Rivers. Its junction with the Wateree forms the Santee, after a south-east course of ten miles.

CONGE, *v. n. & n. s.* Fr. *congé*; Ital. *congedo*; Mid. Lat. *comiatius*. To take leave. Act of reverence; bow; courtesy. The word is sometimes written *congie*.

Where taking *congee*, each one by and by
 Departed to his home in dreadful awe.

Spenser. Mother Hubbard's Tale.

I have *congeed* with the duke, and done my adieu
 With his nearest. *Shakspeare. All's Well.*

Or make a Spanish face with fawning cheer,
 With the island *conge* like a cavalier. *Hall.*

The captain salutes you with *congé* profound,
 And your ladyship curtsies half-way to the ground.

Swift.

CONGES, in architecture, are rings, or ferrels, formerly used in the extremities of wooden pillars, to keep them from splitting, afterwards imitated in stone-work.

CONGE D'ELIRE is French; and signifies, in common law, the king's permission royal to a dean and chapter, in time of vacation, to choose a bishop. The king, as sovereign patron of all archbishoprics, bishoprics, and other ecclesiastical benefices, had in ancient times the free appointment of all ecclesiastical dignities; investing them first per baculum et annulum, and afterwards by his letters patent. In process of time he made the election over to others, under certain forms and conditions; as, that they

should, at every vacation, before they choose, demand of the king a *congé d'elire*, that is, licence to proceed to election.

A woman, when she has made her own choice, for form's sake, sends a *congé d'elire* to her friends.

CONGEAL, *v. a. & n.* } *Fr. congeler*; *It. CONGEALMENT*, *n. s.* } *congellare*; *Sp. congelare*; *Lat. congelare.*
CONGEALABLE, *adj.* }
CONGELATION, *n. s.* } To convert into ice; to fix into a substance by cold; to concreate. Congelation signifies the act of congealing; the state of being congealed. Congealable that which may be congealed; and congealment the concretion produced.

Little she weend that love he close conceald;
 Yet still he wasted as the snow *congeald*,
 When the bright sunne his beames thereon doth beat.

Spenser. Faerie Queene.
 Oh, gentlemen, see! see! dead Henry's wounds
 Open their *congealed* mouths, and bleed afresh.

Shakspeare. Richard III.
 Too much sadness hath *congealed* your blood. *Id.*
 Enter the city, clip your wives, your friends;
 Tell them your feats, whilst they with joyful tears
 Wash the *congealment* from your wounds.

Id. Antony and Cleopatra.
 In the midst of molten lead, when it beginneth to *congeal*, make a little dent, into which put quicksilver wrapt in linen, and it will fix and run no more, and endure the hammer. *Bacon.*

The consistencies of bodies are very divers: dense, rare, tangible, pneumatical, fixed, hard, soft, *congealable*, not *congealable*, liquefiable, not liquefiable. *Id.*
 Many waters and springs will never freeze; and many parts in rivers and lakes, where there are mineral eruptions, will still persist without *congelation*.

Browne's Vulgar Errors.
 When water *congeals*, the surface of the ice is smooth and level, as the surface of the water was before. *Burnet's Theory.*

There are *congelations* of the redundant water, precipitations, and many other operations. *Arbutnot on Air.*

The chymists define salt, from some of its properties, to be a body fixable in the fire, and *congealable* again by cold into brittle glesbes or crystals.

Id. on Aliments.
 In whose capacious womb
 A vapoury deluge lies, to snow *congeald*.

Thomson. Winter.
 If the moon had no atmosphere at the time of its elevation from the earth, or if its atmosphere was afterwards stolen from it by the earth's attraction, the water on the moon would rise quickly into vapour; and the cold produced by a certain quantity of this evaporation would *congeal* the remainder of it. *Darwin.*

Mr. Hunter by very curious experiments discovered that the living principle in fish, in vegetables, and even in eggs and seeds, possesses a power of resisting *congelation*. *Id.*

And if we now and then a sigh must heave
 At quitting even those we quit in strife,
 No doubt we weep for those the heart endears—
 That is, till deeper griefs *congeal* our tears.

Byron. Don Juan.
 How long in his damp trance young Juan lay,
 He knew not, for the earth was gone for him,
 And time had nothing more of night nor day
 For his *congealing* blood, and senses dim. *Id.*

CONGELATION is applicable to metals, when they resume their solid form after being heated; to water when it freezes, to wax, spermaceti, &c. when they become solid after having been rendered fluid by heat; and, in general, to all processes, where the whole substance of the fluid is converted into a solid: but it differs from crystallisation; because, in the latter process, though the salt passes from a fluid to a solid state, a considerable quantity of liquid is always left. The process of congealation, in all cases, dependz upon, or is at least accompanied with, the emission of heat, as has been evinced by experiments made not only in water, but on spermaceti, wax, &c.; for in all these, though the thermometer immersed in them continued, while fluid, to descend gradually till a certain period, yet it was as constantly observed to remain stationary, or even to ascend, while the congealation went on. The most difficult metal, of which the congealation has been actually ascertained, is mercury. This was long thought capable of resisting any degree of cold whatever; and it is only within these few years that its congealation, by artificial means, was known, and still more lately, that some climates were found to be so severe as to congeal this fluid by the cold of the atmosphere. See *COLD*.

CONGEMINATION, *n. s.* 'old *Fr. congeminatio*; *Lat. congeminatio*. A doubling; a frequent repeating.

CONGENERATE, *v. a.* } *Fr. congénere*,
CO'NGENER, *n. s.* } adjective, used only
CONGENERACY, *n. s.* } in anatomy and botany;
CONGENEROUS, *adj.* } *Ital. adj.*
CONGENEROUSNESS, } *congénere*; Latin,
congenerare. The verb, which is little used, signifies to beget; to cause. Congener, which is adopted, without alteration, from the Latin, means that which is of the same kind or stock.

The cherry-tree has been often grafted on the laurel, to which it is a *congener*. *Miller.*
 Those bodies, being of a *congenerous* nature, do readily receive the impressions of their nature. *Browne's Vulgar Errors.*

From extreme and lasting colds proceeds a great run of apoplexies, and other *congenerous* diseases. *Arbutnot on Air.*

CONGENIAL, *adj.* } *Lat. con and genus.*
CONGENIALITY, *n. s.* } Partaking of the same
CONGENIALNESS, *n. s.* } nature or disposition;
CONGENIOUS, *n. s.* } similar in feelings and habits; suitable, beneficial, adapted to. Congenious, which means being of the same kind, is obsolete.

He sprung, without any help, by a kind of *congenial* composure, as we may term it, to the likeness of our late sovereign and master. *Wotton.*

You look with pleasure on those things which are somewhat *congenial*, and of a remote kindred to your own conceptions. *Dryden's Dedicat. of Jew.*

In the blood thus dropped there remains a spirit of life *congenious* to that in the body. *Hales.*

Smit with the love of sister arts we came,
 And met *congenial*, mingling flame with flame.

Popo.
 He acquires a courage, and stiffness of opinion, not at all *congenial* with him. *Swift.*

And light along the fairy Pleasure,
Her green robes glittering to the morn,
Wantons on silken wing. And goblins all
To the damp dungeon shrink, or hoary hall,
Or westward, with impetuous flight,
Shoot to the desert realms of their *congenial* night.
Beattie.

If e'er in dusky cave or midnight bower
The young Endymion bless'd your tender care;
If e'er you felt the sympathetic power,
Congenial spirits in pure essence share;
Let me, fair queen of eve! in thy still hour,
Clasp her I love; like thee, most chaste, most fair.
Leftley.

Whate'er the theme—through every age and clime,
Congenial passions meet the' according rhyme:
The pride of Glory—Pity's sigh sincere—
Youth's ardent blush—and Beauty's virgin tear.
Sheridan.

Congenial to my pensive breast
O'er shadowing clouds the skies invest;
Fast falling showers deform the glade,
No cheering ray dispels the shade. *Huddesford.*
—————All is gentle: nought
Stirs rudely; but, *congenial* with the night,
Whatever walks is gliding like a spright.
Byron. The Day of Venice.

CONGENITE, *adj.* Lat. *congenitus*. Of the same birth; born with another; connate; begotten together

Many conclusions of moral and intellectual truths, seen, upon this account, to be *congenite* with us, conatural to us, and engraven in the very frame of the soul. *Hale's Origin of Mankind.*

Did we learn an alphabet in our embryo-state? And how comes it to pass, that we are not aware of any such *cony-nite* apprehensions. *Glanville's Sccepis.*

CONGER, *n. s.* Lat. *congrus*; Gr. γογγρος. The sea-eel.

Many fish, whose shape and nature are much like the eel, frequent both the sea and fresh rivers; as the mighty *conger*, taken often in the Severn. *Walton's Angler.*

CONGER, in zoology. See **MURÆNA**.

CONGER EEL'S HEAD, is a charge borne in heraldry; as *argent*, a conger's head couped on a pale, name Gascoigne, a family from the Isle of Ely.

CONGERRIES, *n. s.* Lat. A mass of small bodies heaped up together.

The air is nothing but a *congeries*, or heap of small, and for the most part, of flexible particles, of several sizes, and of all kinds of figures. *Boyle.*

Each bud has a leaf, which is its lungs, appropriated to it, and the bark of the tree is a *congeries* of the roots of these individual buds. *Darwin.*

CONGEST, *v. a.* } Lat. *congrerere*, *con-*

CONGESTABLE, *adj.* } *gestum*. To heap up;

CONGESTION, *n. s.* } to accumulate; to collect together; to bring into one mass. Congestion is, a heaping together; formation of a mass; a collection of pus, as in abscesses.

Yet his *congested* wealth shall melt like snow.

Sandys.

Congestion is then said to be the cause of a tumour, when the growth of it is slow, and without pain.

Wiseman.

CONGIARIUM, in antiquity, a largess or bounty of money, given by the Roman emperors to the people, upon certain occasions, by the hands of certain officers called *sequesters*, or *divisores*. Tiberius, Caligula, and Nero, stand in history among the most profuse in their *congiarii* to the people. Nero was the first who commemorated his corruption by stamping the money with which he bribed the slaves of Rome, with the image and superscription of baseness. The type of the medals or coins which represented, and were struck for the *congiarii*, exhibited the tyrant seated upon his *suggestum*, or chair, borne up by men, giving a *tessera*, or ticket.

CONGIARY, *n. s.* Lat. *congiarium*, from *congius*, a measure of corn. A gift distributed to the Roman people or soldiery, originally in corn, afterwards in money.

We see on them the emperor and general officers, standing as they distributed a *congiary* to the soldiers or people. *Addison.*

CONGIUS, a liquid measure of the ancient Romans, containing one-quarter of the amphora, one-quarter of the urna, or six sextarii. The congius, in English measure, contains 2,070,676 solid inches; that is, seven pints 4942 solid inches.

CONGLACIATE, *v. n.* } Lat. *conglaciare*.

CONGLACIATION, *n. s.* } To convert into ice; to effect congelation. The state of being converted into, the act of converting into, ice.

If crystal be a stone, it is concreted by a mineral spirit, and lapidifical principles; for, while it remained in a fluid body, it was a subject very unfit for proper *conglaciation*. *Brownie.*

No other doth properly *conglaciate* but water: for the determination of quicksilver is properly fixation, and that of milk coagulation. *Id. Vulgar Errors.*

CONGLETON, a market-town of Cheshire, seated on the Dane. It has considerable manufactories of silk, cotton, and leather gloves; with a market on Saturday. The town is governed by a mayor and six aldermen, and is extremely clean and neat in its appearance. There is also a small but elegant chapel of ease. It is seven miles south of Macclesfield, and 164 north-west of London.

CONGLOBATE, *v. a. & adj.* } Lat. *congl-*

CONGLOBE, *v. a.* } *bare*, from *con*

CONGLOBATELY, *adv.* } and *globus*, a

CONGLOBATION, *n. s.* } ball. To col-

CONGLOBULATE, *v. n.* } lect into a globular mass; to aggregate into a hard ball; to come together into a round mass. The act of forming such a mass; the mass itself. Dryden uses the adjective, *conglobate*. with the accent on the second syllable: 'Were fixed *congl'obate* in his soul.'

Then he founded, then *conglobed*

Like things to like. *Milton's Paradise Lost.*

Thither they

Hasted with glad precipitance, up-rolled,

As drops on dust *conglobing* from the dry *Id.*

In this spawn are discerned many specks, or little *congl'obations*, which in time become black. *Brownie.*

The testicle, as is said, is one large *congl'obated* gland, consisting of soft fibres, all in one convolution.

Grew.

Fluids are separated from the blood in the liver, and the other *conglobate* and conglomerate glands.

Cheyne's Philosophical Principles.

For all their centre found,

Hung to the goddess, and cohered around :

Not closer, orb in orb *conglobed*, are seen

The buzzing bees about their dusky queen.

Pope's Dunciad.

Compressed and *conglobated* into one gross and general idea. *Johnson.*

A number of them *conglobulate* together, by flying round and round. *Id.*

CONGLOMERATE GLANDS. See ANATOMY.

CONGLOMERATE, *v. a. & adj.* } Lat. *con-*

CONGLOMERATION, *n. s.* } *glomerare,*

from *con* and *glomerare*. To wind round, to form a bottom of thread, is the idea conveyed by the root of these words. The English verb also signifies to collect into a ball ; to intertwine separate fibres into one spherical mass ; to gather into masses. The meanings of the adjective and noun are obvious.

The beams of light, when they are multiplied and *conglomerate*, generate heat. *Bacon's Natural History.*

The multiplication and *conglomeration* of sounds doth generate rarefaction of the air. *Id.*

The liver is one great *conglomerated* gland, composed of innumerable small glands, each of which consisteth of soft fibres, in a distinct or separate convolution. *Greiv's Cosmologia.*

Fluids are separated in the liver, and the other *conglobate* and *conglomerate* glands.

Cheyne's Philosophical Principles.

CONGLOMERATE FLOWERS are those growing on a branching foot-stalk, to which they are irregularly but closely connected. This mode of inflorescence is opposed to that in which the flowers are irregularly and loosely supported on their foot-stalks, hence termed a diffuse panicle. See PANICLE. The term is exemplified in several species of the poa, fescue grass, and agrostis.

CONGLOMERATE GLANDS. See ANATOMY.

CONGLUTINATE, *v. a., v. n., & adj.* } French

CONGLUTINATION, *n. s.* } *conglu-*

CONGLUTINATIVE, *adj.* } *tin-*

CONGLUTINATOR, *n. s.* } *It. con-*

glutinare ; Span. *conglutinar* ; Lat. *conglutinare*. The original meaning of *conglutinate* is, to glue together ; whence, to effect a reunion of parts ; to cause to adhere ; to cement ; to heal wounds ; to unite by the intervention of a callus. Conglutinative remedies are *conglutinators* ; that is, remedies capable of making wounds unite, of producing conglutination.

Starch, which is nothing but the flower of bran, will make a clinging paste, the which will *conglutinate* some things. *Sir W. Petty.*

The cause is a temperate *conglutination* ; for both bodies are clammy and viscous, and do bridle the deflux of humours to the hurts. *Bacon's Natural History.*

To this elongation of the fibres is owing the union or *conglutination* of parts separated by a wound.

Arbutnot on Aliments.

The osteocolla is recommended as a *conglutinator* of broken bones.

Woodward on Fossils.

CONGO, an extensive country in the south-west of Africa ; it is bounded on the north by the river Zaire, or Congo, which separates it from Loango ; and on the west by the Atlantic. The

interior limits of the country are, at present, uncertain ; the observations of our modern travellers having been, principally, directed towards the exploration of the river Zaire, rather than to the extent of the country. It is supposed, however, to extend several hundred miles in every direction.

Angola and Benguela are situated to the south ; whilst the eastern frontier is stated to be composed of lofty and rugged mountains, inhabited by the savage tribe of the Giagas, who frequently make desolating incursions into the territory of Congo.

Before the expedition to explore the river Zaire, undertaken by captain Tuckey in 1816, we could scarcely be said to have any certain knowledge respecting the general appearance of the country. The missionaries, sent by the church of Rome, were, prior to this expedition, our only authorities, and their reports of the great splendor and civilisation of Congo have since been discovered to be much exaggerated. Captain Tuckey found the country far from being highly cultivated. He states that the alluvial banks, indeed, as far up as Embomma are covered with luxuriant verdure ; but this is the effect of nature and not of cultivation. Higher up the river Zaire, he found bare mountains from 2000 to 3000 feet in height, composed chiefly of mica slate, sienite, and quartz ; the villages and cultivated spots are, for the most part, situated in the ravines and tops of these mountains. Farther up still, the mountains open, and allow the river to flow in a wider channel. They are composed here of limestone and clay, and the greater part of the surface is fit for cultivation.

The vegetable productions of Congo appear to be ample, and, for several of the most valuable, it seems to have been indebted to the Portuguese. The large trees are only found in the valleys, or thinly sprinkled over the sides and summits of the hills ; those which principally characterise the landscape, and appear to be very general along the whole extent of the shores, are the *adansonia*, *bombax pentandrum*, *anthoaleista*, *masanga* of the natives (the genus related to *cecropia*), *elaeis Guiniensis*, *raphia rimifera*, and *pandanus coadlabrum*. On the alluvial banks, the mangrove, mixed with the palm, the *adansonia*, and the *bombax*, with occasional clusters of the Egyptian papyrus, forms the grand feature of vegetation. The principal articles of food are maize, cassava, both sweet and bitter, two kinds of pulse, the *cytisis cajaa*, and a species of *phaseolas*, and ground nuts (*arachis hypogaea*). The common yam, and another species of *dioscoxia*, so bitter as to require four days boiling to free it from its pernicious qualities ; sugar-cane, capsicum, and tobacco, are among the alimentary plants of secondary importance. The principal fruits are the plantain, pine-apples,—the first a native of the East and the other of the West Indies, pumpkins, the papaw, limes, oranges, the tamarind, and a fruit about the size of a plum, called *safa*. The plant, however, of the most importance to the natives, is the *elaeis Guiniensis*, or oil-palm, which flourishes here as in all parts of Western Africa, and is, to the inhabitants of Congo, what the cocoa-tree is to many of the Asiatic islanders. From the juice of this tree they make their best

palm wine, a beverage which is found extremely pleasant and refreshing.

The fruits indigenous to Congo, are the anona *Senegalensis*, *sarcocepholas*, a species of cream-fruit, *chrysobolaras icaca*, a species of ximenta, and another of antidesiva. Professor Smith, the celebrated botanist attached to the expedition already alluded to, enumerates 620 species and genera of plants, in his Herbarium, which he had collected in Congo; of these only about 250 are absolutely new; nearly an equal number flourish in other parts of equinoctial Africa: and about seventy are found in other regions within the tropics. No natural order, that is absolutely new, exists in Professor Smith's Herbarium, nor nas one family been found peculiar to equinoctial Africa.
